One of the central problems in understanding how life could have originated is posed by the interdependence of modern systems of informational molecules, such as DNA, and functional molecules such as proteins. Consideration of this problem led to speculation by the pioneers of molecular biology in the 1960s, most notably by Francis Crick, that catalytic RNA combining informational and functional properties might provide a solution to the seemingly intractable 'chicken-and-egg' problem. But such ideas were pure speculation until Altman and Cech, both working on RNA processing systems, demonstrated that RNA can indeed have catalytic properties similar to those of protein enzymes.

Altman's work concerned the bacterial enzyme ribonuclease P, which catalyses a specific cleavage reaction in the synthesis of mature tRNA molecules from larger precursors. In the 1970s Altman and colleagues had shown that ribonuclease P has RNA and protein components, both of which are essential for its enzymatic activity. They thought the RNA may be involved in recognizing the RNA substrates of ribonuclease P, but at first did not consider a catalytic role for the RNA component to be a serious possibility.

Meanwhile, Thomas Cech and his colleagues were investigating the process by which the 'intervening sequence' of the precursor of a ribosomal RNA of the protozoan *Tetrahymena thermophila* is excised and the flanking 'exons' joined to make the mature ribosomal RNA product.

In 1982 Cech's group obtained conclusive evidence that this excision and ligation process can occur spontaneously in the absence of any protein catalyst (*Cell* **31**, 147–157; 1982). Although not true catalysis, Cech's discovery provided the first firm evidence that RNA may be capable of specific catalysis. Altman and colleagues went on to find conditions in which the RNA component of ribonuclease P could, in the absence of protein, catalyse the maturation of tRNA (*Cell* **35**, 849–857; 1983).

Celebrations Colorado style, Thomas Cech (left) and at Yale, Sidney Altman. (AP.)

Following this pioneering work many examples of RNA catalysis have been discovered. In 1986 Cech's group showed that part of the RNA excised from the *Tetrahymena* ribosomal RNA precursor has catalytic activity comparable to that of protein enzymes. Among the variety of reactions catalysed by this RNA — all variations on the basic theme of transesterification — one, synthesis of polycytidylic acid from pentacytidylic acid substrate, bore a striking resemblance to RNA polymerization.

A further step towards realizing Crick's speculation of an RNA molecule with replicase properties has recently been taken by the construction of a derivative of Cech's *Tetrahymena* RNA catalyst that catalyses the ligation of multiple oligonucleotides aligned on an external template (*Nature* **339**, 519–522; 1989).

The practical consequences inherent in these discoveries stem from the prospect of being able to manipulate specific RNA molecules in cells with RNA catalysts. An important step towards this goal was achieved last year by the construction of RNA catalysts derived from 'self-cleaving' plant-virus satellite RNA capable of cleaving other RNA molecules at highly specific, predetermined positions. This opens the possibility of using RNA catalysts to block the expression of specific genes in cells and organisms, may also lead to a new way of preventing virus infections, and has already led to a patents dispute involving Cech (*Nature* **341**, 473; 1989).

Geoffrey North

NOBEL DISPUTE

French researcher asks for share

Paris

LAST week's award of the Nobel prize in medicine to the Americans, J. Michael Bishop and Harold E. Varmus (see *Nature* 341, 475; 12 October 1989), has been greeted with sourness in France.

Dominique Stehelin, who is now director of research at a National Scientific Research Centre (CNRS) laboratory at the Pasteur Institute in Lille, said last week that it was he who carried out the work that led to the demonstration of the cellular character of oncogenes. A postdoctoral fellow in Bishop and Varmus' laboratory in the early 1970s, Stehelin was the first author of papers in *Nature* and the *Journal of Molecular Biology* announcing the discovery.

"I did all the work from A to Z", Stehelin told Agence France Presse on hearing that he would not share the Nobel with Bishop and Varmus.

Stehelin has since softened his position, saying that he does not contest the decision of the Nobel jury, but still wonders why they could not have added a third name to the prize. Meanwhile, the director-general of CNRS, Francois Kourilsky, issued a statement congratulating Bishop and Varmus on the award but adding that "on this occasion, CNRS wishes to salute the role played by one of its researchers, Dominique Stehelin, in this discovery".

This role was sufficiently significant, says the statement, to earn Stehelin the Rosen and Griffuel prizes and the CNRS silver medal. Peter Coles

■ **Bishop and Varmus have not commented directly on Stehelin's complaint, but numerous colleagues have come to their defence. According to the *Washington Post*, Peter Vogt, the fourth author on the *Nature* paper, said that Stehelin's unhappiness was "understandable but regrettable". A statement issued by the University of California at San Francisco made it clear that Stehelin's work was done "under supervision".** □

NOBEL PRIZES: PHYSICS

Measures towards success

Washington

THIS year's award of the Nobel prize for physics, half going to Norman F. Ramsey of Harvard University and half shared by Hans G. Dehmelt of the University of Washington in Seattle and Wolfgang Paul of the University of Bonn, has its roots in the beginnings of quantum theory.

The technical accomplishments of all three prizewinners rely on the phenomenon, first recognized by Einstein, of stimulated emission, wherein an atom in an excited electronic state can be induced to fall to a state of lower energy by electromagnetic radiation of the frequency corresponding to the energy difference.

The prizewinners' innovations have been instrumental in testing the quantum theory of atoms with exquisite precision, and have also led to precise standards of measurement of general utility. The atomic clock, which depends on Ramsey's inventions, is now used to define one second of time as 9,192,631,770 oscillations of between hyperfine levels of caesium.

Ramsey's great achievement was the refinement of I. I. Rabi's method for inducing atomic transitions by passing excited atoms through a magnetic field and an electromagnetic radiation field of fixed frequency. Ramsey added a second radiation field, setting up an interference pattern with the first in which photons of the precise frequency needed to induce an atomic transition existed only in certain places. This restriction of the volume in which transitions could occur increased the coherence of the photons thus emitted.

A later development, by Ramsey and Daniel Kleppner, was the invention of the hydrogen maser, in which excited atoms are held in a suitably tuned cavity. The maser not only allowed direct high-precision studies of the structure of the hydrogen atom, but also became widely used as a reference source in, for example, interferometric techniques in radio-astronomy. The accurate frequency standard provided by the hydrogen maser allows observed radio signals at physically separated radiotelescopes to be compared, and from the differences high-resolution radio maps are calculated.

In Ramsey's work and its offshoots, precision is obtained by persuading many identical atoms to emit radiation coherently. In the work of Paul and Dehmelt, the goal has been to trap single ions or electrons in a suitable arrangement of electromagnetic fields, so that their properties may be studied directly. Paul's work began in the 1950s in Bonn, where he first invented methods to focus ions using multipolar magnetic fields (as is done in particle accelerators today), separate ions of different mass, and store them in traps of electric fields with a pervading radiofrequency radiation field.

The trap works by ingenious application of Einstein's rules for the emission and absorption of radiation. An ion moving towards a source of electromagnetic radiation can be excited to a higher level by picking up a photon of suitable frequency. But when it de-excites, it emits a photon whose frequency, with respect to the stationary apparatus, is slightly increased by the amount of the Doppler effect. The ion therefore emits a photon of higher frequency than that absorbed, and the extra energy is taken out of the ion's motion: in other words, it slows down. This principle works to cool ions, and to prevent them from moving out of the trapping volume.

Dehmelt and his colleagues developed a slightly different method, the Penning trap, which they used in 1973 to capture and hold a single electron. This has enabled Dehmelt's group to measure the electron's g-factor — the departure of its magnetic moment from the classical value — to an accuracy of a few parts in 1,000 million. Like Ramsey's work with the hydrogen maser, such measurements have tested (and so far confirmed) the correctness of the quantum theory of electrodynamics. The award of the Nobel prize to Ramsey, Paul and Dehmelt recognizes that physics, at bottom, is the art of measuring nature.

SCIENCE JOURNALS

Breaking the paper barrier

New Delhi

A 30-YEAR-OLD policy banning the publication of Indian editions of foreign science and technology periodicals in order to protect local publishers may soon be abandoned. The Indian Department of Science and Technology (DST) has been asked by the government to re-examine the issue, and has sent out a two-page questionnaire to a cross-section of the scientific community in India.

The present policy was instituted in the mid-1950s because the government feared that local editions brought out by foreign publishers would suffocate domestic journals. This was part of a general Indian policy to achieve self-reliance in science and technology that included import limitations and customs barriers to protect local technological products.

But five years ago the government made an about-turn, liberalizing the technology importation policy because it found that protectionism had led only to industrial stagnation. The government is now wondering if the publishing policy should be relaxed, for similar reasons: Indian publishing has not prospered, and the cost of importing foreign journals is an increasing burden.

The opinion poll is being carried out by *Current Science*, whose editor, S. Ramaseshan, says there are two extreme views on the issue. Behind the restrictive policy lies the idea that publication of foreign science and technology journals in India could "undermine not only the efforts to build up our own journals, but even the formation of a cohesive and committed scientific community".

But the opposing view is that local editions of foreign journals are essential if India's scientific and technological activities are to be on a par with international standards. Competition, Rameseshan believes, would "improve the quality of our science and our journals".

Some 15,000 scientists are expected to participate in the opinion poll, and DST hopes to make its recommendations to the government by the beginning of next year. Respondents will be asked whether or not they want a revision of the policy, and to list up to ten foreign journals that they would like see published in local editions.

For the time being, the French magazine *La Recherche* is the only foreign scientific publication appearing in India in English, but the demand for foreign science journals in a country with over 1,200 research establishments and 125 universities is something that overseas publishers are not likely to ignore.

K.S. Jayaraman

WORLD PSYCHIATRIC ASSOCIATION

Soviet's Freudian slip

Athens

THE Soviet All-Union of Psychiatrists and Narcologists (AUSPN) is preparing a special session on Freudian theory, and has already begun publishing Freud's collected works, Soviet psychiatrists told a press conference at the World Psychiatric Conference this week. Speaking on "Psychiatry and *Perestroika*", the Soviet team pointed out that (as with so many changes in the Soviet Union today), the reappearance of Freud, and other innovators of psychological theory, was a return to the "Leninist" policies of the 1920s, after decades in which the whole concept of psychoanalysis and the unconscious was republished as "pseudo-science". Soviet psychology and psychiatry were, they stressed, originally founded on the German school of the early 1920s, and the AUSPN now wanted to resume its contacts with Germans and other West European psychiatric associations.

"*Perestroika*," said Dr Alexsandr Karpov, of the USSR Ministry of Health, "like any great social event, has its effect on mental health too".

What the AUSPN was seeking, of course, was reinstatement in the World Psychiatric Association (WPA), from which (under its previous name of the All-Union Society of Psychiatrists and Neuropathologists it resigned in 1983 to avoid expulsion over the issue of the political use of psychiatry. The key issue, therefore, was whether or not Soviet psychiatry had mended its ways, or could be seen to have done so while its former leaders, such as Dr Marat Vartanyan and Dr N. Zharikov still held high office in the AUSPN. (Both of these were present in Athens; neither was at the press conference.) The Soviet team stressed that things are changing in Soviet psychiatry, urging that it would be better to look at a more positive future than to the painful events of the past. But human rights campaigners were distributing a letter just received from Aleksandr Podrabinek, of the unofficial Independent Psychiatric Association in Moscow, listing a number of new admissions over the past few months, which, the letter said, were made on political grounds.

The Soviet team argued that *perestroika* is a slow process, that there are now stronger legal guarantees of patients' rights, the "psychiatric register" of former patients has been greatly reduced, and that earlier this year, a "verification team" of US psychiatrists and lawyers had been given wide facilities to visit Soviet psychiatric hospitals.

The Soviet team, was challenged by Dr Anatolic Koryagin — a former Soviet psychiatrist who was himself incarcerated for having revealed (in *The Lancet*) details of Soviet abuses — about the AUSPN's letter of withdrawal from the WPA in 1983. If they recognized that political abuse of psychiatry had taken place in the past, he asked, how did they evaluate the signatures of the current leaders of Soviet psychiatry on the letter of resignation, which accused the UK Royal College of Psychiatrists of conducting a "slanderous campaign against them".

The President of the Royal College added his own demand for a formal apology; particularly as the chief signatory to the 1983 letter, Dr Georgii Morozov was, in 1988, elected an honorary president of the WPA — elected, it was stressed, by democratic, secret ballot and not imposed from above. The Soviet panel were reluctant to apologize on Georgii Morozov's behalf, but promised to inform him that an apology had been asked for. They would go no further than admitting that "mistakes were made in the past". But to the majority of press, psychiatrists and campaigners at the meeting, this answer was clearly insufficient. **Vera Rich**

RESEARCH FUNDS

MIT in the red

Boston

IN what could be a portent of difficult financial times ahead, the Massachusetts Institute of Technology (MIT) has posted its first budget deficit in six years. A recent university report discloses a shortfall of more than $5 million for the 1989 fiscal year, which ended in June. The deficit is largely a result of falling income at the Lincoln Laboratory, an MIT affiliate which is supported almost entirely by the Department of Defense (DoD).

This year's deficit could be early evidence of coming financial difficulties because of the university's substantial dependence on military funding. Kenneth A. Smith, vice president for research at the university, has predicted "significant cutbacks in military funds" for research by the 1991 fiscal year.

The deficit comes despite a small decrease in expenses from fiscal year 1988 which the university attributes to layoffs of subcontractors at Lincoln Laboratory. But operating revenues decreased faster. The resulting shortfall of more than $11 million was reduced to $5 million by consideration of nearly $6 million in unrestricted gifts and other income.

More worrying for the university is that the deficit has arisen in spite of a 19.3 per cent increase in support from non-federal sources. Fiscal year 1989 marked the first time that industry and other private funds surpassed the National Science Foundation as the fourth largest sponsor of research. The top three remained the same: the Department of Energy, the Department of Health and Human Services, and the DoD.

Despite rising concern, there are few solid proposals for replacing lost income. But Kosta Tsipis, director of the Program in Science and Technology for International Security and long a critic of MIT's reliance on military research dollars, is to hold a "high-level" meeting of corporate, academic, government and military leaders later this year to explore the prospects for converting some of the military-sponsored work at the university to more constructive research. Seth Shulman

GALILEO

Legal moves fail

Washington

AFTER surviving an eleventh-hour legal attack, the launch of the space shuttle *Atlantis*, carrying the Jupiter probe Galileo, had to be postponed from 12 October because of a technical problem. But by Saturday all was well again, and the launch had been rescheduled for early this week — Tuesday, 17 October. The unexpected delay gave the anti-nuclear opponents of Galileo's flight a chance to appeal against the earlier legal ruling, but that too failed.

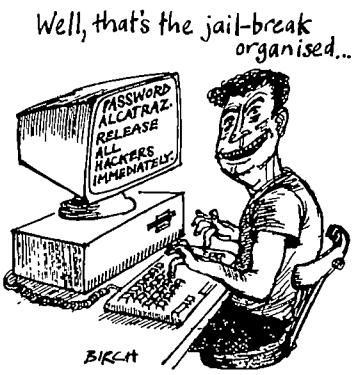
The delay, announced by the National Aeronautics and Space Administration (NASA) only an hour after it had been given legal permission to continue the countdown, was due to a malfunction in a computer controlling one of the main shuttle engines. Although the computer has a back-up, mission controllers decided to replace the offending part. This was successfully done on Saturday, allowing a new lift-off time at 12.57 p.m. on the following Tuesday.

A request for an injunction against the launch of Atlantis, on the grounds that the environmental hazards from accidental dispersion of the plutonium in Galileo's power generators had been improperly assessed (see *Nature* **341**, 374; 1989), was turned down by Judge Oliver Gasch in the US District Court for the District of Columbia late last Tuesday.

Gasch declared that the court was not willing "to substitute its judgement ... for that of the government agency", a pronouncement that NASA took as a vindication of its risk assessment analysis but which Andrew Kimbrell, who argued for the injunction on behalf of the Foundation on Economic Trends, said was an abdication of the court's responsibility.

With legal recourse having failed, protesters may now attempt to make good their promise to prevent the launch by infiltrating the Kennedy Space Center and occupying the launch area. NASA has tightened security at the site, but is not publicly anticipating trouble. **David Lindley**

COMPUTER ABUSE



Plan to outlaw hacking

London

THE definition of three new crimes to deal with the growing problem of computer hacking, the unauthorized entry into computer systems, is recommended in a British Law Commission report released last week. The commission, a statutory body advising the British government on the legal aspects of new legislation, was asked to review the present legal status of hacking.

The commission says that British criminal law at present fails to cover two main problems: the "costs, disruption and uncertainty" caused to owners by unauthorized entry to their computer systems and the loss and damage caused by alterations of stored data and programs. "Such attacks can be particularly serious if they are directed against computers performing industrial or commercial operations", the report says.

The report, *Criminal Law — Computer Misuse*, concludes that an adequate deterrent cannot be constructed simply by

patching up existing criminal law, and recommends the definition of three new crimes. Any attempt to gain entry to a computer system, whether for gain or for fun, should be a criminal offence with a maximum penalty of three months in jail. Entry with intent to commit a crime should be treated more severely, with a maximum penalty of five years' imprisonment.

The commission recommends that there should be a third more serious offence consisting of attempting "intentionally and without authority" to alter data or programs with the use of worms, viruses or logic bombs, or of circulating disks infected with such devices. The maximum penalty for this offence would also be five years' imprisonment. The Trade and Industry Secretary, Mr Nicholas Ridley, welcomed the report and was "inclined to accept" its recommendations.

Law Commissioner Richard Buxton QC, who heads the Law Commission's criminal law team, said the system was designed to operate in a graded manner. The first offence would deter the "widespread activity" of hacking. This will be reinforced by the two more serious offences. Buxton added that the rules were carefully designed not to penalize computer users whose waywardness consists merely of carelessness. **Ben Webb**

■ The prosecution of Cornell University graduate student Robert T. Morris can succeed only by proving that he knowingly intended to gain unauthorized access to a number of federal computers with the virus that infected the Internet system a year ago (see *Nature* **340**, 329; 1989). It has been argued by some in the United States that any law that made unauthorized entry a crime, regardless of intent or authority, would be unworkable: in the Morris case, a number of network users put together "patches" that protected computers from infection and distributed them, in a freelance manner, across the network. Under a law that condemned Morris, would they also be guilty? □

MICROELECTRONICS

JESSI enters critical phase

Munich

As part of its commitment to the European microelectronics initiative known as JESSI (Joint European Submicron Silicon), West Germany announced on 28 September the foundation of a new institute for silicon technology. The institute will concentrate on the development of smaller memory chips, with a diameter of 0.5 micrometres or less, using X-ray lithography and other techniques.

JESSI, a collaboration of five European governments, the European Economic Commission and three of the largest electronics companies in Europe, is an ambitious attempt to combine research with product development across national borders (see *Nature* **339**, 652; 1989). The latest announcement reflects the strong West German commitment to JESSI at a time when critical decisions are being made concerning individual JESSI projects and possible US participation.

The Fraunhofer Society for the Advancement of Applied Science was expected to confirm its sponsorship of the institute at a meeting on 18 October. The new institute, which will be located in Itzehoe in the north German *Land* of Schleswig-Holstein, will differ from other Fraunhofer Institutes in that just a few large firms, including European chip producers such as Siemens and Philips, will participate in the research and benefit from the results.

The Research Ministry (BMFT) and the *Land* of Schleswig-Holstein will share the construction and equipment costs of DM 400 million ($210 million). When the institute begins operation, by 1992, industry will provide 20 per cent of the staff and will share in salaries and costs.

The Fraunhofer Institute for Microstructure in West Berlin, which has worked with X-ray lithography in the past, will lose some researchers to the Itzehoe institute. BMFT has announced that the Berlin institute will be restructured, causing some upset among West Berlin politicians, who had hoped that JESSI would help attract new high-technology investment to their isolated city.

The most important decision that is expected in the next few months concerns participation by the United States in JESSI. The Europeans have made the participation of firms such as IBM contingent on a reciprocal acceptance of European companies, or their US subsidiaries, into the US electronics consortium Sematech. Both JESSI and Sematech are founded on the principle that Japan is the main competition in designing and producing chips.

According to a spokesman, JESSI representatives paid a visit on Sematech directors in the United States in mid-September and agreed to meet again in Munich in December to "explore possible cooperative efforts in standards, university programmes, equipment and materials programmes" and other areas. But despite these overtures, the question of foreign participation may run into obstacles in the US Congress, which would have to agree to change the rules by which Sematech is constituted if European participation is to be permitted.

Steven Dickman

CHANGE OF POST

New direction at ESA

Paris

REIMAR Lüst, in his fifth year as director-general of the European Space Agency (ESA), will move to Hamburg next autumn to be director of meteorology at the Max Planck Institute there.

The move had been expected: the director-general of ESA is elected for a four-year term, but Lüst had been asked to remain for another two years to avoid a change of leadership during important negotiations at The Hague in 1987.

The list of candidates for the next director-general will be closed at the end of this month, and Lüst's successor will be chosen at the ESA council meeting next March. An ESA spokesman would not speculate on the favoured candidate, but said that "it will not be a German" — successive director-generals have so far never come from the same member state. Meanwhile, Lüst has taken up another function as president of the West German Humboldt-stiftung. Peter Coles

US SCIENCE EDUCATION

Actions, not words, by 2007

Berkeley

DECLARING a state of emergency in science reminiscent of the days of Sputnik, a group of some 250 notables met here last week at the urging of Energy Secretary James Watkins and Nobel laureate Glenn Seaborg to find ways of improving the much-lamented state of mathematics and science education in the United States.

Among the actions called for were a mobilization of the country's many national laboratories, a nationwide teacher training programme and even a musical video to elevate mathematics and science in the minds of American elementary and high school students.

The Maths/Science Education Action Conference, convened at the Lawrence Hall of Science (LHS) in Berkeley from 9 to 11 October, was attended by representatives from education, industry, the National Science Foundation and a host of other government agencies. Its purpose was to identify specific programmes the government can adopt to reverse a steady decline in science and mathematics education.

This decline, demonstrated in several recent studies that show US students lagging behind their counterparts in many developed countries, is widely seen as threatening the technological edge of the United States. "No more talking . . . no more crying about the problem", proclaimed co-host and LHS director Marjorie Gardner. "Let's get on to the solutions. Science is a core subject, not an elective. Science is for everyone."

Despite such an admonishment, the conference was not wholly free of traditional platitudinizing — some speakers espoused such vacuous goals as making US mathematics and science students the best in the world. Nevertheless, some specific recommendations did emerge, which addressed seven areas of concern: teachers; curriculum; underrepresented students; the science student pipeline; inner-city/rural schools; national maths/science literacy; community involvement and professional involvement.

A final report is not yet available, but a draft summarizing the working group proposals argued for the development, within a year, of a streamlined process for awarding credentials to prospective teachers and a four-week training programme to reach ten per cent of existing mathematics and science teachers.

One of the conference's chief goals was to find ways to reach women and inner city and minority youth, who are traditionally underrepresented in science. It was hoped that, by establishing programmes at various national laboratories, the Department of Energy (DoE) would serve as a model for other federal agencies to help revitalize science education in targeted districts.

To that end, Watkins stopped at the Fermi National Accelerator Laboratory outside Chicago, on the way to the conference, to break ground for a $1.2 million science education centre. And Watkins told the conference that he expected to have 20 national laboratories starting similar activities within the year.

A working group chaired by Bob Goodwin, executive director of the White House Initiative on Historically Black Colleges & Universities, suggested that this effort could be expanded by bringing in private industry, colleges and state and local governments to help reach underrepresented students. The group proposed identifying ten school districts, and initiating programmes at half of them within the year. Another group suggested the music video as a way to reach those students usually left out of science and mathematics culture.

The draft summary urged the President's science adviser to establish and chair an interagency committee that would extend the DoE model by developing partnerships with other government agencies. This body would then work with the National Science Foundation (NSF) and the Department of Education on a national mathematics and science curriculum. The science adviser was also asked to establish alliances between the government and ten per cent of the country's school districts in the next year.

Those present clearly appreciated that a cabinet member had taken time to be the host of such a meeting: Watkins received a standing ovation near the end of the tiring final day. For his part, Watkins praised the reports of the working groups, saying that the bulk of them was "so much better than what we have, that we have to get a document out". Watkins also assured the meeting that its suggestions would be incorporated into DOE's National Energy Strategy, a draft of which is to be submitted to President Bush on 1 April 1990.

Although many of these ideas are aimed at producing short-term benefits, the goal of the conference was to enable the class of 2007 (children born this year) to acquire the knowledge necessary to build the country's technical and scientific base. This date is symbolic because it marks the 50th anniversary of the launching of the Soviet satellite Sputnik, an event important to conference organizers.

"We're facing many of the same problems in science and mathematics education that we faced then", said Seaborg, citing poor teacher training, an outmoded curriculum and general public illiteracy on science issues.

To put into practice the meeting's broad proposals will mean reorganizing and refocusing the already substantial resources committed to science and mathematics education, said Watkins. It will also, he admitted, take more money. "Will I have a fight? Probably. Will I get it? Yes — because I'll go and gripe to the President and he'll support me."

Robert Buderi

COMMERCIALIZATION

BTG looks towards Europe

London

THE British Technology Group (BTG), Britain's still-public technology transfer organization, is to spread its sphere of activity into mainland Europe. The group subsumes the activities of the National Research Development Corporation originally formed to patent and license the intellectual property rights (IPR) to scientific and technological discoveries made by academic researchers.

BTG has been asked by the European Institute of Technology (EIT), an international consortium supported by IBM Europe, AT&T, Glaxo, Enichem and Kodak, to deal also with innovations arising from the scientific programmes it supports at European universities. John Morton, company secretary of BTG, said EIT had recognized BTG's position as "market leader in IPR management".

EIT's objective is to stimulate cooperation between industry and universities by sponsoring research. In its first year it received nearly 1,000 research proposals, of which it supported 35, with funds ranging from 10,000 to 15,000 ECUs (1 European Currency Unit = £0.69). In phase II of the 1989 programme, nine projects will be selected, and will receive up to 750,000 ECUs each. BTG will be responsible for all the patenting and licensing of any technology in which the member companies of EIT decide they are not interested. Among other things, it will fall to BTG to decide how academics should be rewarded for their work.

Historically BTG has worked almost exclusively on British inventions, but it has lately realized that many overseas companies may have portfolios with under-developed inventions which BTG's expertise in technology and intellectual property protection skills could turn into money-spinners. BTG has strong links with the United States, and recent deals have established a firm base in Japan. The move onto the European mainland is the next stage of BTG's international expansion, and BTG has identified medium and small European enterprises as a potential growth area.

Ben Webb

CHERNOBYL CLEAN-UP

Resettlement demands

Moscow

TENS of thousands of people carried banners through the streets of Minsk, the capital city of Byelorussia, on 30 September to protest against delays and misinformation over the clean-up of contamination from the Chernobyl nuclear reactor explosion of April 1986. Although city authorities did not give official approval, the three-hour rally, attended by seven people's deputies of the USSR (members of parliament), went smoothly.

Ivan Lishtvan, vice-president of the Byelorussian Academy of Sciences, told the crowd that in Byelorussia, the republic worst affected by the Chernobyl disaster, the "optimistic forecasts" of the All-Union Committee for Radiation Defence, which has been directing the official clean-up, have proved "fallacious". He said that although the number of people affected by various illnesses is still growing, and although little is known about the effects of low-levels of radiation, the USSR Ministry of Health insists that people can live in contaminated areas.

"They want to make people live where they shouldn't", Lishtvan said, declaring that in the opinion of the Byelorussian Academy, people living in affected areas should be resettled without delay. The concerns of the academy have been echoed by the local population, which wants the federal clean-up programme in Byelorussia to heed the Academy's advice. In a few weeks, a new plan will be brought before the Byelorussian Supreme Soviet.

Academician Yevgeni Velikhov, a vice-president of the All-Union academy as well as director of the Kurchatov Institut and a people's deputy of the USSR, spoke at the rally to declare the support of the Union Academy of Sciences for the Byelorussian view.

Although there is now a policy of distributing personal dosimeters to the populace, the technical problem of making enough has yet to be addressed.

Some 1,500 dosimeters will have been produced by the end of the year, Velikhow reported, and over 100,000 in 1990. But this may not be enough to give a dosimeter to everyone who wants one, given that few people in Byelorussia are prepared to accept official statements on the extent of contamination.

Stanislav Shushkevich, pro-rector of the Byelorussian University and also a people's deputy, complained that from the outset there had been little truthful information. A demand was made for criminal charges, for misuse of office, to be laid against certain former and current officials said to be responsible for the atmosphere of secrecy around the Chernobyl explosion and its aftermath. "This will be done, sooner or later. There is no escaping an ecological Nuremberg", said author and people's deputy Ales Adamovich, who charged that because the magnitude of the disaster had been kept concealed, Byelorussia had been allocated insufficient federal money for the clean-up. And some of those resources that had been allocated were wasted, for example in the construction of new villages which will have to be evacuated anyway.

The relief fund for the affected areas of Byelorussia is now getting numerous donations, but is is not clear who will control the money, and how it will be distributed. *Izvestia* has recently reported that 542 million roubles from the federal charity fund, donated shortly after the Chernobyl explosion, was used to cover state expenses at the power station. To avoid similar misuses, speakers at the rally agreed that people's deputies for the affected areas of Byelorussia should have control of the donated funds. Whether the Supreme Soviet of Byelorussia listens to its deputies and its electorate will emerge later this month.

Igor Germenchuk/ *Novosti, Moscow*

SCIENCE IN SCHOOLS

No more creationism

San Francisco

THE state of California, which accounts for about 11 per cent of the US school textbook market, has given publishers a broad hint about the wares they should be offering. Last week, its influential Curriculum Commission voted overwhelmingly to give evolution a central place in its science framework, and to relegate creation theory to a religious setting. After a public hearing on 25 October, the state Board of Education is expected to vote on the framework in November. Textbook guidelines are revised every seven years in California, and the new recommendations will take effect in 1992. California is closely watched by publishers, who economize by producing standardized textbooks.

"Creation science is not a science and has no place in the science curriculum", said Curriculum Commission chairman Dan Chernow, a former member of the Board of Education. Creationism, he added, should be discussed along with other religious issues — either in the history and social science curriculum or the English and language arts curriculum. Robert Buderi

US AGRICULTURAL RESEARCH

Call for more spending

Washington

THE US National Research Council (NRC), the research arm of the national academies of science, medicine and engineering, is calling for an increase of $500 million in federal spending on competitive grants for research into agriculture, food and the environment.

This ambitious proposal from the NRC's board of agriculture appeared almost on the eve of President George Bush's expected announcement of across-the-board cuts in federal spending in order to meet deficit reduction targets.

But instead of watering down its recommendations in the light of the current financial climate, the NRC report, published on 6 October, argues that a substantial investment in agricultural research will improve international competitiveness and help reduce the budget deficit. The increase should be made next year and should not come from the reallocation of existing research programmes, it says.

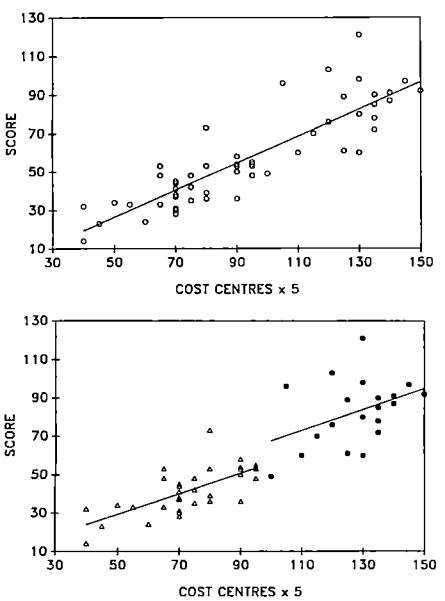
NRC complains that there has been "little, if any, real growth" in agricultural research spending since 1955. Last year, the US Department of Agriculture's (USDA's) total research spending was only 4.6 per cent of the total federal research budget. While problems in agriculture increase, the report says, opportunities are missed: the slow application of biotechnology to agriculture is cited as a notable problem.

NRC proposes that a new independent office be set up within USDA's office of science and education to administer new grants, and that six programme areas should be established: plant systems; animal systems; nutrition, food quality and health; natural resources and the environment; engineering, products and processes; and markets, trade and policy. At present USDA spends only $40 million on competitive research grants, and in a narrower field of research.

NRC also recommends that USDA should increase the duration of grants from the present two years, as well as their size, which now averages only $50,000 a year. By contrast, the average grant awarded by the National Institutes of Health is $155,000.

The aim of the suggested programme would be to secure the proven high economic return on investment in agricultural research. Other objectives would be to attract the best talent from the entire research sector into agricultural research, to expand knowledge in all the disciplines underpinning agriculture as well as contributing to advances in other areas.

Officials in the Department of Agriculture support the proposal, but its fate will be not be known until the president submits his 1991 budget proposal to Congress. **Christine McGourty**



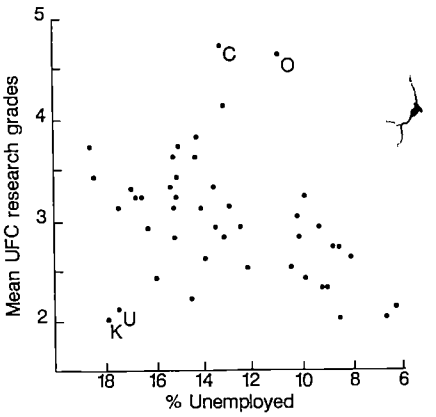
UK university rankings

SIR—The recent university research rankings by the Universities Funding Council have been based upon percentage scores, in which each university's actual score is expressed as a percentage of the maximum score the university would have obtained had each of its "cost centres" scored a 5. To get a fuller picture, it is useful to plot the published data graphically. The upper graph in the figure shows each university as a point located by its actual score (vertical axis) and its potential score (horizontal axis). Such plots are frequently used in assessing biometric data, for example in examining the relation between the size of an animal's brain and its overall body weight.

The graph shows, unsurprisingly, a high correlation ($r = 0.87$) between actual and potential scores. In other words, large institutions tend to have larger scores than smaller ones. Some universities he conspicuously above the regression line: these are the ones picked out in newspapers as "the best". Others fall below the regression line: these are the "worst".

There is a visual impression from the graph that the universities may fall into two groupings (lower graph): a group of larger institutions (cost centres $\times 5 > 100$) where the correlation between score and size is relatively weak ($r = 0.40$), and a group of smaller ones where the correlation is stronger ($r \times 0.69$). The group of larger universities has scores greater than those expected from their size alone, as indicated by the slightly elevated position of their regression line.

It can, however, be a serious conceptual error to take position relative to the regression line as the sole measure of merit. For example, if we do the same with the size of an animal's eye relative to its total size, we arrive at the incorrect conclusion that the eye of a sparrow is better than the eye of a horse. In fact, the best single indicator of the performance of an eye is its absolute, not its relative size. A small eye is adversely affected by diffraction and by poor magnification, no matter how minuscule the size of head in which it is lodged.



Top, universities' actual score (y axis), compared to potential score (x axis), bottom

Something similar, it seems to me, might be true of universities. Reliance on percentage scores will put pressure on universities to close weaker departments and thus reduce their diversity. This could be disastrous, particularly in the case of universities that are already small. Deciding that particular universities should 'specialize' in key areas simply freezes the intellectual *status quo*. Who is to say that tomorrow's electrical engineers will not need to interact with tomorrow's geographers? The best indicator of merit (if we want one) ought to combine absolute size and relative performance. As an example, one could add the rank order of size to the rank order of distance above the regression line. Taking into account only the percentage score leads to the absurd conclusion that a university can somehow improve by closing down its weaker departments, or by amalgamating them all into a cost centre for epistemological investigations. A university that teaches no foreign languages, or which has no statistics department, might then come out as 'better' than one that teaches a reputable range of subjects. No doubt this is what the government is seeking to bring about, with the able assistance of the chief executive of the council: but there is no reason why academics should connive in destroying their own institutions.

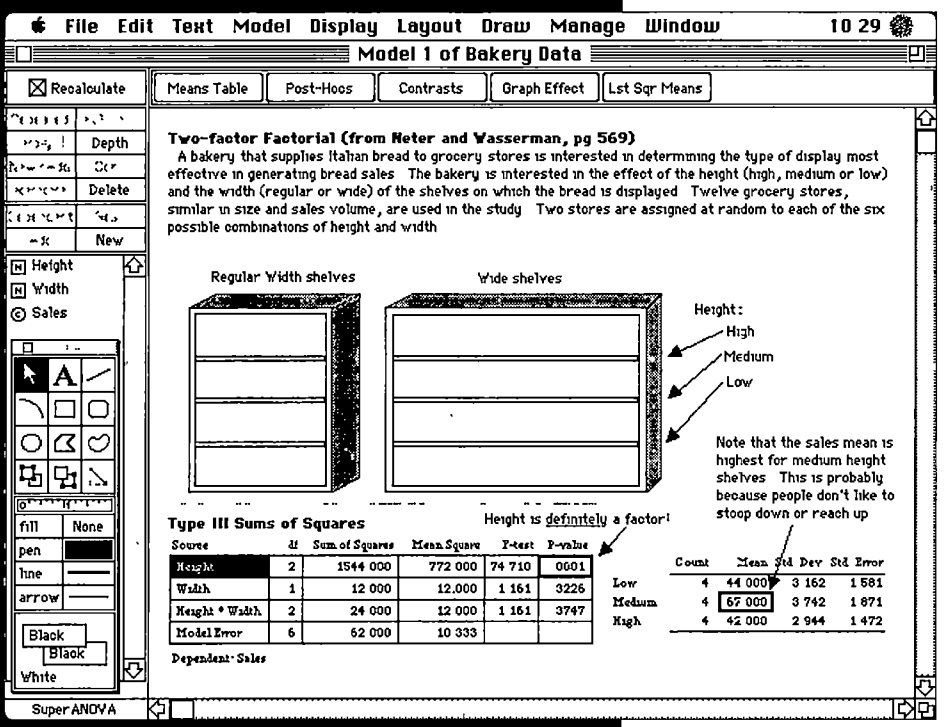
SIR—In the UK university system, activity in research is widely held to nurture good teaching, but supporting evidence is hard to come by. Teaching quality is difficult to assess directly but might be reflected in the employment record of graduates. In conjunction with the Universities Funding Council (UFC) research grades, employment records reported annually by the *Financial Times* provide some basis for evaluating the relationship between research and teaching performances at the level of the institution.

Far from the anticipated positive relationship between mean research grades and teaching quality, as indicated by the percentage of graduates unemployed or in short-term work, there is a negative association (see figure). The relationship is stronger in the absence of Oxford and Cambridge, which are exceptional in terms of research performance and whose graduates are moderately successful in avoiding the dole queue, and the universities of Ulster and Keele, where research and teaching both fare badly using the present criteria. No university excels in both research gradings and graduate employment, and, in general, poor research gradings are associated with enhanced graduate prospects of gaining a foothold in the world of work.



The relationship between mean research grades and percentage of graduates in 1988 unemployment or in short-term employment in 45 UK universities. Data published in the *Financial Times* on 26 August and 13 September 1989 respectively. Research grades for the colleges of the Universities of London and Wales were collated on the basis of numbers of departments assessed. Spearman's rank correlations for all universities and all universities except Oxford (O), Cambridge (C), Ulster (U) and Keele (K), are 0.400 (t=2.860, P <0.01) and 0 675 (t=5.712, P <0.001) respectively

The 1970s and 1980s have been traumatic decades for UK universities. The view, or rather the aspiration, that research and teaching quality is uniform throughout the system is no longer tenable. There are seemingly great disparities within the system, reflecting the relative importance placed on teaching and research in individual universities. It is possible that universities that have done badly in the recent UFC grading exercise have paid the penalty of over-investment in course development and teaching. Lack of time, equipment and manpower for research and the pursuit of funds from non-UFC sources ensure low research grades. Perhaps the major error of the underachievers in research, however, is to put the interests of their students ahead of personal ambition in their chosen field of research.

SuperANOVA

Accessible General Linear Modeling for the Macintosh™

- ANOVA, ANCOVA
- MANOVA, MANCOVA
- Multiple regression
- Repeated measures using multivariate or univariate methods
- Interaction and residual plots
- Means tables
- Unbalanced and missing cell designs
- A priori contrasts
- Post hoc means tests, including Tukey's HSD, Tukey Compromise, Duncan's New Multiple Range, Games-Howell, Fisher's LSD, Scheffé's S, SNK, and others
- Design and save models for later application to different data sets
- Canned model designs, including repeated measures, Latin squares, and split-plots
- A complete Macintosh interface

SuperANOVA is a *revolutionary* implementation of general linear modeling. Now you can easily build complex models without learning a command language.

SuperANOVA is from Abacus Concepts, the developers of the award-winning StatView line of statistical software for the Macintosh.

Custom Peptides

Quality and Quantity to meet your needs

CRB is one of the world's leading suppliers of pure, custom designed peptides. Using Fmoc-polyamide solid-phase synthesis and our economical continuous flow column technology, we'll make the peptide you need. At the purity you require. In the quantity you need. On any scale from milligram to kilogram.

Custom Synthesis of Peptides
Three reagent qualities to provide maximum economy in your peptide application.

1 Standard Reagent Grade – supplied with hplc profile and amino acid analysis.
2 Immunological Reagent Grade – for antibody production. Purity minimum 80%. Supplied with hplc profile, amino acid analysis and FAB mass spectrometric analysis result.
3 Bioassay Reagent (bR) Grade – for biological studies. Supplied by net peptide weight at a guaranteed purity in excess of 95% with complete analytical specification.

Large Scale Peptide Production
To meet the growing demands of the Pharmaceutical Industry, we have developed a new process to manufacture bulk peptides under GMP conditions. This NEW 'Continuous Flow Column Process' offers a rapid and economic method for large scale production.

CRB also offers:

Custom Conjugation of Peptides to Carrier Proteins

Custom Synthesis of High Purity Tritiated Peptides

To discuss your application and requirement – Contact us now.

GET THE LATEST IN BIOLOGY AN

9-10 November 1989 at the C

CONFERENCE SESSIONS

1 HUMAN GENETIC DISEASE

James Crow, U. of Winsconsin (chairman); Louis Kunkel, Harvard Medical School; Gerd Utermann, University of Innsbruck; Kenneth Kidd, Yale University; Eric Lander, Whitehead Institute (rapporteur)

2 PROSPECTS FOR GENE THERAPY

Leon Rosenberg, Yale (chairman); Irving Weissman, Stanford University; Richard Mulligan, Whitehead Institute; French Anderson, NIH; David Baltimore, Whitehead Institute (rapporteur)

3 HUMAN GENE RESEARCH:

PANEL DISCUSSION

4 TRANSGENIC MOUSE MODELS

Richard Palmiter, Washington U. (chairman); Douglas Hanahan, University of California SF; Erwin Wagner, IMP Vienna; Ron Evans, Salk Institute; Brigid Hogan, Vanderbilt U. (rapporteur)

5 GENE DISRUPTION AND DEVELOPMENT

Mario Capecchi, U. of Utah (chairman); Fred Alt, Columbia University; Janet Rossant, University of Toronto; Peter Gruss, Max Planck Institute Gottingen; Bruce Alberts, U. of California SF (rapporteur)

Nature has reserved a limited number of rooms at special rates for conferences delegates. When you register we will forward a special hotel reservation card for your convenience.

ATION

UMAN DISEASE

ey Plaza Hotel, Boston, MA

How readily can the genes responsible for predisposition to conditions such as ischaemic heart disease or schizophrenia be identified? What are the prospects of human gene therapy? Are transgenic animals the key to understanding the precise genetic control of development? How much more sophisticated can methods of genetic manipulation and gene identification become?

These are among the major questions that will be addressed by the distinguished speakers at Nature's 1989 conference. A chairman will outline the context and aims of each session, the speakers will review their area of expertise and report the latest advances, and a rapporteur will draw out the implications of each session. There will be a panel discussion of the ethical and legal problems raised by human gene research and therapy. For the convenience of delegates, the second day of the conference will finish in mid-afternoon, whereas the first day will be extended by the panel session followed by a wine and cheese reception.

We expect the conference to sell out well before opening, so urge you to make sure of your place now by returning the form below.

REGISTRATION FEES
Standard rate including reception $350
Special rate for full-time academics and government employees only $300

Sponsor's liability: should the conference be cancelled or postponed for any reason, the sponsor's liability is limited to the return of the registration fee. Cancellation policy: all cancellations must be received in writing. Cancellations before 30 August will be subject to $25 service charge. No refunds will be made after that date. Registrants unable to attend may send a substitute.

Please reserve ____ places for me at Nature's conference 9–10 Nov 1989 Total amound due: US$_____

Dog-days for the Soviet Union

Soviet scientists live more in the real world than most. The long winter that lies ahead will be particularly taxing for them. Mere organization will not help.

Moscow

THIS place is not in particularly good shape just now. The weather is neither one thing nor the other, neither mid-continentally baking hot nor arctic, and everything is a greyish-brown and damp. This is, of course, what farmers call the back-end of the year, when in the West they sell up their lifetime's plot of land and move into bungalows. In the Soviet Union, where land by definition belongs to the state, the Supreme Soviet, many people's nightly television fix has been the debate on the new law on property that, among other things, would allow land to be leased. One senses that merely to be the opening round in a five-year ideological argument. In any case, there are no bungalows into which to move.

Of the past five years of reform, only one ingredient can be counted an unmitigated success: *glasnost*. The daily and weekly newspapers and the periodicals keep turning up such interesting material that people find themselves distracted from more serious pursuits by the need to learn about the recent past. One weekly newspaper has begun to publish information about the Soviet development of nuclear weapons, complete with Beira's threat to Kurchatov that his head would be off if the first few kilograms of plutonium did not explode as promised. A principal in those events cannot accept that Beira also demanded that the estimated critical mass should be checked "with our man". *Novy Mir* has made a start on Solzhenzkin. But even free-floating *glasnost* has not yet seriously begun on Stalin's engineered famine in the Ukraine.

People also talk more freely of the situation in which they are. Some volunteer that all the past seventy years have been mistaken. Some say that it can only be a matter of time before communism is abandoned, but go on to say, "You realize I couldn't have been talking this way two years ago." Their worry, which they hide quite well, is that they may not be able to talk as freely two years from now, either.

This, it may be worth remarking, is not a selected but a general impression. Most people, when asked, answer along these lines, but usually with some degree of caution. One particularly clever man, having marshalled all the arguments why the system must be radically changed, denied that he meant that communism is dead.

Another disconcerting feature of *glasnost* is the licence it appears to have generated. Taxi-drivers habitually ask foreigners whether they have dollars to sell. (They usually offer 5 roubles to the dollar, well below the supposed black market rate of 10 or more.) Crowds of men outside hotel restaurants do the same. They seem curiously unafraid of the consequences, which on paper are horrendous; one must assume that they have squared their protectors.

It seems also to be well-established that all the newly-created cooperatives intended two years ago as the cutting edge of Mr Mikhail Gorbachev's economic reforms are not always as white as driven snow. The principle, of course, is that a cooperative can be a business in some kind of Western sense, charging what prices seem economic, but that its members must share equally in its profits. There is one account of a bookselling cooperative that bought stocks of best-selling books from a state-owned bookshop, and then sold them at more than twice the state-fixed price. It is supposed that the cooperative fixed the bookshop manager. It is no wonder that Mr Gorbachev turned last week's attack on the cooperatives in the Supreme Soviet only by referring the law concerned back to a committee.

Glasnost has also licensed magic. One television programme is said to offer healing by faith, courtesy of the public microwave channels. There is a strikingly un-Marxist credulousness in the air. Theses on the nature of the Universe (and its origin) are two a penny. Is this what the twelfth century was like?

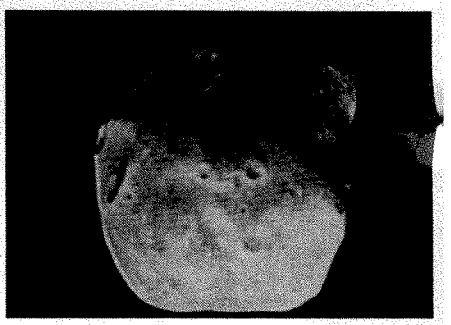
Political parties are also springing up, but amateurishly. The founder of the Ecological Socialist Party, a mathematician turned environmental database keeper who is also a member of the real Party, was able to talk for longer about his party's objectives than about its membership (twelve) and its method of getting itself elected.

Glasnost, and compliance with the Helsinki accords, has also encouraged emigration, which is a mixed blessing. High authorities at the Soviet Academy of Sciences are sufficiently alarmed at the rate at which able people are leaving for the United States that they wonder whether a tax on overseas earnings would be equitable — and, no doubt, whether it could be administered. More poignantly, a woman friend confesses that she feels quite lonely now that her friends, mostly Jewish, are living in California and Texas.

What seems to worry people most is the problem of the republics, the partners with the Russian Republic (reaching from the Baltic at Leningrad to the Pacific) in the Union of Soviet Socialist Republics. Many people are haunted that the problem of Armenia and Azerbajan has not been dealt with.

The Armenian problem is a kind of civil war, more costly to the Soviet Union than ever Ulster has been to Britain. There is much gloomy talk about the prospect that there will be a more general civil war. One person (who himself hunts deer) says that there are too many illegal guns in people's hands. But the more common gloomy supposition of how the present confusion will be unwound is that there will be a military government for a time. If the security of the Soviet Union should be threatened, would it not be logical that the military people, even reduced in number by 400,000 as they have been, should step in?

In the circumstances, it is remarkable that there has been any progress. Yet the past two years have seen enormous change. People travel with unprecedented freedom. Almost always, they return. Laboratories are being better equipped, but exceedingly slowly, at a fraction of the rate that might allow them to "catch up". Perhaps the best sign, in the past two years, has been the appointment of really able scientists as heads of academy institutes on no other basis than merit; many of the new guard are not even members of the Party. Yet the cleverest are happiest when their laboratories are aweay from Moscow.



That, for the scientific enterprise in the Soviet Union, must be where the future lies. For better or worse, the Soviet Academy of Sciences is still well-respected and could regain much of the influence it is losing to the State Committee on Science and Technology if it were more efficient. There is endless speculation as to how the next elections, due in the first half of next year, will resdistribute people among positions, but the academy and its members have hardly begun to think of how it should itself be organized. Yet as things are, the weekly meetings of the governing council (praesidium) bring together more than 50 people from all over the Soviet Union for a day-long meeting. A little procedural *perestroika* would not come amiss.

John Maddox

PHOBOS 2 ENCOUNTER

Probing martian space . . .

Mark Saunders

The eponymous Phobos.

OF all the planets, Mars must surely evoke the greatest sense of mystery and fascination. Excitement was high, therefore, when earlier this year the Soviet Phobos 2 spacecraft became the first probe since NASA's two Viking landers in 1976 to reach the red planet. Despite the premature failure of both its spacecraft (Phobos 1 was lost while *en route* to Mars and contact with Phobos 2 ceased after just 57 days in orbit; Sagdeev and Zakharov discuss these failures in detail in their review article[1] on page 581), the ambitious Phobos project did return new and important scientific data, as is clear from the initial results reported on pages 581–618 of this issue.

Before the Phobos mission, martian space was even less well understood than the space environments of the more distant planets Mercury, Jupiter and Saturn. The only previous missions to study aspects of the interaction of the solar wind with Mars were the Mariner 4 flyby in 1965, which at closest approach barely crossed the bow shock, and three Soviet orbiters (Mars 2, 3 and 5) in the early 1970s. The Soviet spacecraft all orbited at least 1,000 km above Mars, an altitude that is too high for critical aspects of the solar-wind interaction to be studied. Interpretation of the scant Soviet recordings thus became controversial, especially on the question of Mars's intrinsic magnetic field. So, before Phobos, it was unclear whether the solar wind at Mars was deflected totally by an ionosphere (as at Venus) or whether a magnetic field (as at Earth) also played a role.

During its 57 days in orbit Phobos 2 made made 5 elliptical orbits with a closest approach to Mars of 850 km followed by more than 100 circular orbits at an altitude of 6,000 km. But the elliptical orbits are proving the most rewarding, because they reached the lower altitudes vital for answering the key questions. Remote data concerning the surfaces of Mars and Phobos (the larger of the two martian moons after which the mission was named) are highlighted in the accompanying News and Views article by McKinnon opposite.

Although Phobos 2's orbits were not ideal for probing the plasma around Mars, initial data analyses[2-4] suggest that the character of martian space is controlled by the solar wind and its embedded interplanetary magnetic field (IMF), but there is also tentative evidence of a weak planetary field[2]. Major boundaries are similar to those found at Venus, although the scales are much shorter, indicating the relevance of microscopic plasma effects. The outward leakage of Mars's thin atmosphere seems large enough to have influenced the planet's evolution. These findings may have wider relevance in the Solar System as similar space environments occur at Venus, at the comets and at Titan.

One important result to emerge from the new data is that the solar wind at Mars interacts dominantly with an ionosphere[2]. This is clear from the Phobos 2 passes through the martian wake, which show that at altitudes of 6,000 km, Mars has a well-developed magnetic tail consisting of two opposed bundles of magnetic flux (called lobes) whose polarities are controlled by the direction of the upstream IMF (Fig. 1). Thus it seems that most of the magnetic flux in the martian magnetotail is accreted from the solar wind in the manner Alfven[5] proposed for comet magnetic tails and which is observed at Venus. Such tail accretion is a direct consequence of the interaction of a flowing magnetized plasma with a planetary ionosphere. The magnetometer team[2] also report spectral-analysis evidence for a small internal magnetic field, but this result should be viewed with caution until substantiated further.

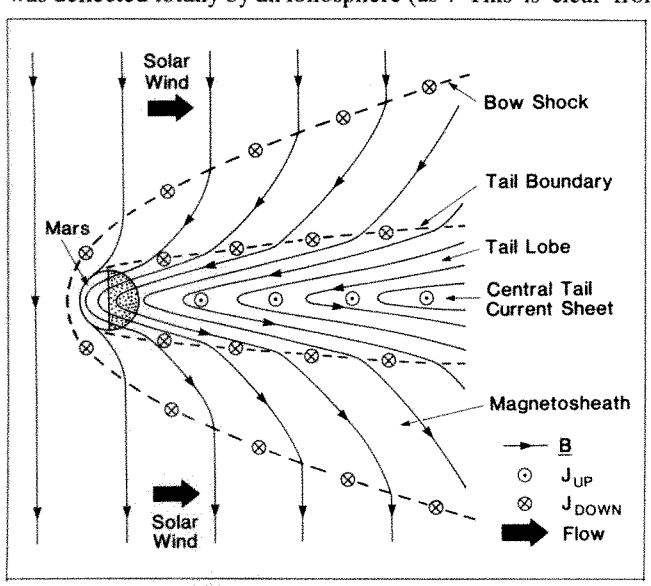


FIG. 1 Electromagnetic aspects of the interaction of the solar wind (bold arrows) with Mars, consistent with the initial Phobos 2 findings and illustrating the structure of an accreted magnetic tail. The diagram is drawn for steady east–west interplanetary magnetic field conditions and field lines, *B*, are shown projected into the plane of the figure. Circled dots and crosses indicate the direction of electric current flow *J*.

Also important is the information obtained on the plasma and magnetic structure of Mars's dayside space environment, the only region probed thoroughly on previous missions being the bow shock. Figure 2 illustrates the main dayside boundaries and their locations, inferred from measurements from the elliptical orbits. The plasma boundary nearest the planet has been called the planetopause (though ionopause may be a more appropriate term). It separates the shocked solar-wind plasma in the magnetosheath from a region of purely ionospheric plasma consisting mainly of atomic oxygen O^+. The interplanetary magnetic field piles up above the planetopause (Fig. 2), but a large amount of magnetic flux penetrates this boundary because the solar wind's dynamic pressure usually exceeds the plasma pressure of Mars's ionosphere[6]. The compressional stresses exerted on these slowly moving dayside field lines will act to squeeze plasma tailward along the draped magnetic field. This effect may be significant for the observed[3,4] downtail escape of ionospheric plasma.

A further source of tailward plasma loss is the accelerated field-aligned beams of O^+, with energies of up to several kilo-electron volts, found[3,4] near the central tail current sheet. The origin of these beams remains uncertain. One suggestion is that they arise from the same acceleration process occurring above the Earth's auroral oval; however, Phobos 2 did not detect aurorae at Mars. An alternative origin may involve current sheet acceleration associated with the hairpin bend of the field lines in the central tail (Fig. 1).

The tailwards escape of ionospheric plasma in the martian wake is estimated to be between 1 and 2 kilograms per second[3,4]. This rate may seem small but, if maintained, it would result in Mars's thin atmosphere being lost within 10^9 years, which is less than the age of the Solar System. Assuming that the atmosphere was replenished through the evaporation of surface water or ice frozen into the martian soil, then the weakness (or absence) of an intrinsic magnetic field may well have contributed to the loss of

both the martian atmosphere and hydrosphere through the direct impact of the magnetized solar wind on the ionosphere.

There is a special aspect of the martian system that makes its plasma environment particularly challenging to understand. Whereas the main features of other planetary environments are described well by the equations of magnetohydrodynamics, in which the motion of all particles is ascribed to a fluid flow, the observed scale sizes at Mars are comparable to the ions' local radii of gyration in the magnetic field (1,000 km for a solar-wind ion). Thus the solar wind's interaction with Mars is modified by effects due to such finite Larmor radii[7]. One clear example of such a microphysics effect is the width of the foot boundary associated with the bow shock[2,8]. As is evident in Fig. 2, the shock foot (a shock precursor one ion-gyroradius wide)

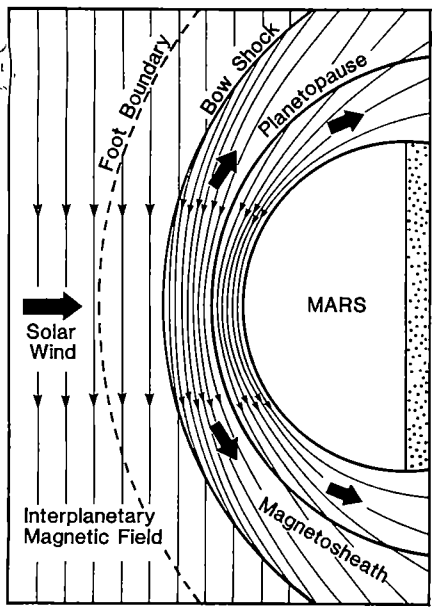

FIG. 2 The dominant dayside features of the solar-wind interactions with Mars seen by Phobos 2. The diagram emphasizes the main boundaries, the magnetic field geometry (arrowed lines) and the plasma flow (solid arrows).

is now comparable in width to the magnetosheath and is not an insignificant feature as it is at Earth.

Further important findings will follow these early analyses, but it is doubtful that Phobos 2 can answer the crucial question of whether Mars has a small or zero intrinsic magnetic field, because the 850 km periapsis (rather than the nominal 500 km) was too high to probe the ionospheric regions where an internal field would be most detectable. Indeed a periapsis as low as 100–200 km may be required for a definitive answer, and this will have to await the planned NASA Mars Observer and Soviet MARS 94 missions. □

. . . and martian surfaces

William B. McKinnon

THE loss of Phobos 2 in Mars orbit is a tragedy, of course, but it is not the end of the story. Although it is not widely recognized, many of the experiments on board were intended for Mars as well as Phobos, and it is probably these experiments that yielded the most new data and that will, eventually, provide the most new scientific understanding. The thermoscan (thermal infrared) images, in particular, are spectacular[9]. They instantly show much of the information previously painstakingly obtained by the Viking IRTM (infrared thermal mapper), and at better spatial resolution. And they allow one quickly to note the relatively warm and cool areas, interpret them in terms of albedos and thermal inertias (that is, soil-like or rock-like thermal properties), and correlate all this with local geology.

The long history of Viking IRTM analyses shows that many factors, such as surface pressure, must be taken into account for proper interpretation, so it is premature to expect detailed geological interpretation at this time. Nevertheless, analysis of thermoscan images can draw on the IRTM experience. For example, high-resolution but broadband thermoscan radiometer data can be combined with lower resolution but multispectral IRTM data for maximum effect.

Phobos 2 also carried an infrared imaging spectrometer (ISM), and was the first spacecraft to do so at another planet. Several hundred spectra of Phobos were obtained along with some tens of thousands of spectra of Mars. The martian spectra sampled most of the principal geological terrains on the planet, with the unfortunate exception of the polar caps. In principle, it should be possible to use the details of the spectra collected to identify or place constraints on the types or amounts of various minerals in the martian soil and bedrock (if exposed). The example in the paper on the ISM results[10] is the relative depth of the water hydration band near 3 μm. The authors are careful not to overinterpret the results, as the depth of an absorption feature does not uniquely indicate the relative amount of the absorber: grain size, the presence of opaque (and hence masking) minerals, degree of crystallinity and even temperature affect spectral band depths.

Refined analyses exploiting the results of years of ground-based spectroscopy should provide more secure identification of primary igneous minerals, and most importantly, perhaps shed some light on the controversy surrounding identification of carbonate-bearing minerals in the martian soil. Carbonate is, naturally enough, a sink for atmospheric CO_2, and its presence may indicate a more aqueous (and clement) Mars in the past.

The spacecraft brought a multichannel infrared radiometer to Mars as well, but the results presented so far concern only Phobos[11]. The data indicate intriguing inhomogeneities in the inner moon's structure and composition. ISM data for Phobos also indicate variations in hydration and silicate spectral features[10]. The 3-μm hydration absorption feature is markedly weaker than for Mars, which may at first seem surprising given that Phobos (and Deimos) are often viewed as captured carbonaceous asteroids and that carbonaceous meteorites are mostly water-rich clay minerals. However, the surfaces of many carbonaceous asteroids, particularly those in the outer asteroid belt, are rather dry, and ground-based spectroscopy has recently shown that Deimos possesses at most only a small absorption feature at 3-μm, implying that it is relatively dry[12]. The ground-based experiment is too difficult to do for Phobos because of scattered light from Mars, but the telescopic and ISM data combined may indicate that Phobos and Deimos are similar carbonaceous bodies with closer to anhydrous surfaces.

It is also interesting to note that the Phobos mission indicates that the moon's density is about 1.95 g cm^{-3}, which is somewhat less than that determined by Viking. The imaging team reports that this is consistent with substantial internal porosity for a rock body[13], which is true, but some noted astronomers still favour an icy interior. Paradoxically, an icy interior would not conflict with a dry surface, because this is what is expected of outer belt asteroids according to current thinking[14]. The prospect of icy moons circling a thirstless desert below is only one of many martian mysteries to be explored by further analysis of Phobos 2 data. □

AIDS

Complexities and strategies

Peter Newmark

SET the difficult task of deciding the best research strategies in AIDS, participants at a recent meeting* were somewhat diverted, but not particularly cheered, by the recent US decision in favour of giving AZT, still the only licensed drug against HIV (human immunodeficiency virus), to those who are HIV-infected but have no symptoms of disease. Several speakers voiced the opinion that the decision was made before it was certain that AZT at an early stage does more than delay progression, in which case it might be wiser to hold back on treatment for more advanced stages of the disease. With the US data not available for scrutiny, N. Clumeck (St Pierre University Hospital, Brussels) announced that equivalent European trials would be continued for the time being.

In any case, AZT is orders of magnitude too expensive to be used in developing countries, which account for about half of the 5–6 million people in the world who are estimated already to be infected with HIV (J. Chin, WHO), although only the tip of that iceberg is so far visible, in the form of a cumulative total of 180,000 cases of AIDS.

As G. Noble (Centers for Disease Control, Atlanta) put it, trying to monitor trends in HIV prediction by extrapolating backwards from HIV cases is becoming extremely antiquated, and will be even less adequate as drugs such as AZT lengthen the time from infection to AIDS. Thus, there is a pressing need for widespread surveys of rates and trends in infection. The ideal system would be random door-to-door surveying, but this is controversial, expensive and subject to an excess of refusals among those most at risk. Testing of anonymous blood samples is better but leaves unanswered the question of the likely cause of infection. What is often lacking, concluded many of the delegates to the conference, is the political leadership necessary to bring about and finance adequate surveys.

Equally lacking is the leadership necessary to promote measures that would reduce the rate of infection of those most at risk. An example of what can be achieved is the reduction in annual infection rates of a cohort of San Francisco homosexuals from 20 per cent in 1982 to 1–3 per cent in the past three years. This is attributed largely to behavioural changes, although if more susceptible individuals were the bulk of the 50 per cent of the cohort that had already become infected by 1982, the annual rate would be bound to have fallen to some extent thereafter even without behavioural change (Current estimates are that AIDS will kill 4 per cent of the population of San Francisco.)

Another example is the fall in the annual infection rate of intravenous drug users in San Francisco in the past two years, associated with a programme of education, the provision of bleach as a needle disinfectant and (in the face of California state law) the promotion of a scheme of needle exchange (D. Francis, Dept. Health Sciences, Berkeley). It was generally concluded that attempts to promote behavioural change work best at a local level based on an adequate understanding of local high-risk practices.

Animal models

Unfortunately, monkeys are still the best animal models, but even they have limitations. More than six years after being innoculated with human brain tissue containing HIV-1 (autopsy samples from what are now known to have been cases of AIDS dementia), chimpanzees show no sign of disease (C. Gajdusek, National Institutes for Health). Lymphadenopathy follows the infection of rhesus monkeys with HIV-2 (G. Hunsmann, German Primate Centre, Gottingen), but after several months no other signs of AIDS have appeared. This is perhaps inevitable, given that a study of Senegalese prostitutes infected over three years ago with HIV-2 has shown it to be far less pathogenic than HIV-1 (M. Essex, Harvard University). So, by fairly general agreement, the best system at present remains the AIDS-like disease that follows infection of rhesus monkeys with simian immunodeficiency virus (SIV) from other species. If the molecularly cloned SIV that kills monkeys in as few as ten days after infection (J. Mullins, Stanford University) is shown to be a viable model for the very much slower HIV-induced diseases, progress should be much speeded.

A potential substitute for the monkey is the cat, which develops an AIDS-like disease when infected with the recently discovered feline immunodeficiency virus. However, its complete sequence shows it to be only a distant relative of HIV (and all other lentiviruses) and epidemiological evidence suggests that it can be transmitted by close contact, unlike HIV (E. Sparger, University of California, Davis). An even more recent rival is the SCID-hu mouse — a genetically immunodeficient mouse with circulating human T cells derived from implanted human fetal liver and thymus. If HIV is given in the thymus or intravenously, it infects thymus cells and replicates there; AZT will inhibit but not completely prevent the infection (J. McCune, SyStemix, Palo Alto). It has yet to be shown, however, that SCID-hu mice can mount an immune response against HIV, so the model is not yet, and may never be, useful for vaccine testing.

Vaccines

The extent of the immune response evoked in 10 volunteers given a vaccine comprising the envelope protein of HIV, made in yeast, with a synthetic muramyl tripeptide adjuvant was reported by D. Dina (Chiron). In most cases, antibodies were produced but the response was neither sustained, nor did it include neutralizing antibodies, which are considered to be essential for protection. It is both on this kind of outcome and on theoretical grounds that the tide of the meeting turned against simple subunit vaccines. At the other extreme is the possibility of using killed-virus vaccines. Delegates were informed, unfortunately second-hand, of the apparently successful protection of a number of rhesus monkeys by a killed-SIV vaccine.

It seems unlikely, however, that killed-HIV vaccines will ever be considered safe enough for human use. Instead, a strong case was made for focusing efforts on live vector viruses, such as vaccinia virus or adenovirus engineered to contain appropriate HIV genes (G. Ada, Johns Hopkins University). These would have the great advantage over subunit vaccines of being able to generate an immune response against cells containing HIV, which is probably the predominant form in which the virus is transmitted. An unsophisticated live vector vaccine would contain, for example, the whole HIV envelope gene; more sophisticated versions would express only those parts that generate strong immunity, including the 9-amino-acid peptide identified by D. Bolognesi (Duke University) as the principal neutralizing epitope on the envelope protein. Antibodies against this epitope do not

A PROBLEM in comparing AIDS research from different laboratories is the lack of standard reagents, including viruses. This is particularly the case in research on vaccines. Help is now at hand in Europe in the form of a new European Communities initiative, known as EVA (European vaccine against AIDS).

Most of EVA's total budget of ECU 2.5 million (£1.8 million) will be used on the production and distribution of reagents. They will be produced in a number of laboratories to agreed specifications. Quality control, storage and distribution will be looked after by the National Institute for Biological Standards and Control in South Mimms, UK, which is open to suggestions as to which reagents are most needed until the end of this month. □

* Institut de la Vie symposium, *Biomedical Research Strategy on AIDS*, Yverdon-les-Bains, 24–28 September 1989

block binding of the protein to its receptor, the CD4 molecule, but prevent fusion of the virus with the cell thereafter.

It is most unlikely that a single epitope will provide sufficiently broad protection against the great variety of strains of HIV. And it was generally agreed that to produce broad T-cell-mediated immunity will require several epitopes. Some, but not much, concern was expressed that the ability of certain antibodies to enhance, rather than prevent, the entry of HIV into cells (J. Levy, University of California, San Francisco) might compromise the use of vaccines.

Another matter of concern, not only to the development of vaccines but also to the understanding of AIDS, emerged from suggestions that the HIV/SIV isolates on which most studies are based may not be representative of disease-causing forms. For example, the SIV with a truncated envelope protein that appears when isolates from macaque monkeys are cultured in the laboratory is the result of adaptation to growth in human cells rather than the predominant form *in vivo* (Mullins)[2].

More dramatically, the most frequently represented variants among the population of HIV molecules found after culturing an isolate are usually only minor components in the uncultured population, sampled directly by polymerase-chain-reaction technology, at least in terms of their *tat* gene sequences (S. Wain-Hobson, Pasteur Institute)[3]. Further studies along these lines should help establish not only whether the most pathogenic variants of HIV and SIV require the help of other variants in order to replicate, as some researchers believe, but also the functional importance of the apparent evolution of HIV variation in individuals during progression towards AIDS (Wain-Hobson; E. Fenyo, Karolinska Institute).

Although it remains unclear exactly how HIV causes disease, and why there is a long period of latency, several new facts have come to light. First, it now seems that the virus is present in a much greater proportion of peripheral blood cells than has been thought, although still only one in every hundred or few hundred cells is infected even in AIDS (D. Ho, University of California, Los Angeles; see also ref. 4). Second, there is increasing evidence that CD8 lymphocytes suppress HIV replication in CD4 cells, perhaps by means of a lymphokine (Levy). Finally, the product of the *tat* gene, secreted from HIV-infected cells, may be one of the factors promoting the development of Kaposi's sarcoma (R. Gallo, National Institutes for Health).

Whereas those at the meeting charged with trying to reach a consensus view on the best strategies to follow were able to select some areas on which to focus, new information on the complexities of HIV and the diseases it causes made it clear how foolhardy it would be to narrow the focus more than a little at present. □

QUANTUM TUNNELLING

Barrier traversal time

Rolf Landauer

Consider a large box with a particle that can escape through a thin tube. The particle spends a long time bouncing around the box until it escapes and then a shorter time in the tube, while escaping. A similar distinction in timescale exists for quantum mechanical tunnelling out of a trap through a barrier, although this has received limited recognition. The time taken by the final escape event has now been measured in a subtle and definitive experiment by a group at Saclay[1].

In classical mechanics, a particle moving sufficiently far against an opposing force field will eventually have its velocity reduced to zero, at which point it will turn around. In quantum mechanics, a particle has some probability of going further and penetrating a barrier or wall, which would certainly stop the classical particle. This tunnelling has been observed and discussed in many contexts such as α-particle emission from nuclei, fusion catalysed by muons, the Esaki diode and the scanning tunnelling microscope. It is frequently maintained that the final tunnelling escape through the barrier takes zero time[2], or that quantum mechanics does not allow us to discuss the timing. The latter view, typically held in casual discussions, is based on a presumption of excessively simple methods of measuring the barrier traversal time.

In the past decade a degree of consensus has emerged in the theory of this barrier traversal time (see, for example, refs 3–7). Although each contributor has a variation of a related viewpoint, the papers all emphasize an expression in which the usual imaginary sign of the momentum in tunnelling, $p=\sqrt{2m(E-U)}$ (U the potential energy exceeding E, the total energy), is disregarded, and the magnitude of that momentum, divided by the mass m, is regarded as a barrier crossing velocity. This barrier traversal time is familiar from instanton theory approaches to tunnelling, but there it is an imaginary time, without physical intepretation. Some controversy continues, for example between Büttiker and myself[8] and Lowe and Collins[9], and between Hauge *et al.*[10] and Leavens and Aers[11].

It has been argued that this expression for the traversal time was confirmed by an experiment[12] in which a tunnelling current was reduced by the presence of a deflecting magnetic field. But this result can be interpreted equally well by direct appeal to the time-independent Schrödinger equation, without use of the traversal time[13]. A more dynamic form of experimental confirmation is desirable. Three such experiments have been proposed, including one which has yielded only preliminary results[14]. A second[15,16] uses a configuration in which, during tunnelling, the electron is attracted to an electrostatic image charge on the electrode which it is leaving. The extent to which this image charge has time to spread, while the electron is tunnelling, is used as a clock for measuring the tunnelling time. The third experiment by Esteve *et al.*[1] has now yielded very clear results. More important than the exact result and its relation to theoretical controversies, is the fact that a timescale associated with the barrier traversal can be measured, and is a real (not imaginary) quantity. The occasional advocacy of complex traversal time is puzzling: we have yet to see a stopwatch with complex numbers on its dial.

Esteve *et al.* use a Josephson junction (an electrical insulator sandwiched by two superconductors) supplied with a constant

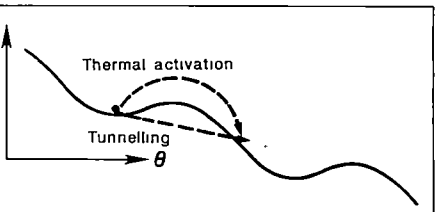

FIG. 1 Metastable states of a circuit containing a Josephson junction Movement along the abscissa, the phase difference across the junction, generates a voltage V: $d\theta/dt = 2eV/\hbar$. The energy U depends on θ and the (constant) current J through the junction according to $U = (J_0\cos\theta - J\theta)\hbar/2e$, where J_0 is the maximum current the junction can carry without a voltage J_0 determines the height of the undulations, and J, the tilt of the 'washboard' potential With $J<J_0$ the potential exhibits pockets of local stability; the circuit can remain in such a metastable state for some time (akin to the particle of the first paragraph rattling in a box) before tunnelling out Resistive dissipation during the tunnelling lowers the energy of the system (the broken arrow indicating tunnelling is not horizontal). The value of the effective resistance depends on whether the barrier traversal time is larger or smaller than the characteristic timescales of the rest of the circuit, and also affects the probability (rate) of tunnelling escapes.

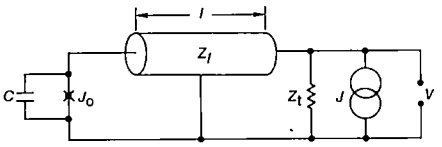

FIG. 2 Circuitry of the experiment by Esteve *et al.*[1] The Josephson junction (✖) passes a current J, less than its critical current J_0, from a constant source, it has a capacitance, C. It is also connected to a 'terminating' resistor, Z_t, through a transmission line Z_l (or delay line) of variable length l (and hence variable delay) The decay of a metastable state is apparent because of the voltage V that is generated and which can be measured. After each decay event, the circuit can be reset, and the time elapsed until the next decay measured.

current. The junction permits the tunnelling of electron pairs through an insulator, with the electrons in the pair coupled by the mechanism responsible for superconductivity in the adjacent electrodes. The state of such a junction is characterized by the difference in quantum-mechanical phase across the insulator, related to the voltage V by $d\theta/dt = 2eV/\hbar$ (e is the electron charge; $\hbar$, Planck's constant; t, time). Esteve *et al.* exploit the fact that the energy of their circuit containing the junction varies with the phase: under the appropriate conditions, there is a series of states of local stability in which the circuit can remain (Fig. 1).

A circuit trapped in one of the metastable wells can escape either by thermal activation over the barrier or by tunnelling quantum mechanically through it (Fig. 1). It is the barrier traversal in the latter process, which dominates at low temperature, that Esteve *et al.* time. Their experiments are carried out at 18 millikelvin and above. In addition to the tunnelling pairs there is a normal current arising from single electrons flowing across the junction. This flow can arise from leakage or from the tunnelling of uncoupled single electrons, and also from current carried through any additional conductor 'shunting' the junction. These are all dissipative transport mechanisms, supplying viscous damping for the motion in the potential depicted in Fig. 1. The viscous forces reduce the probability (or rate) of tunnelling: roughly speaking, the circuit loses energy as it tunnels and so drops further below the barrier, which consequently becomes more impenetrable. By measuring the mean lifetime of the metastable state — simply by timing many decay events — Esteve *et al.* can measure the effective resistance during the barrier traversal and so derive, as described below, the time taken for the traversal itself.

A transmission line, of mechanically variable length and terminated by a resistor, is connected across the junction (Fig. 2). The resistance of the termination is considerably smaller than that of the transmission line, so that voltage waves or pulses propagating towards it are reflected back to the junction. As the circuit tunnels through the potential barrier, $d\theta/dt$ is positive, so that a voltage is generated (as given by the equation above) which propagates down the transmission line.

What effect does the terminating resistor have on the tunnelling event? With a sufficiently long transmission line, the tunnelling event will be concluded before the voltage wave reaches the resistor. The dissipative energy losses will be determined by the characteristic impedance of the transmission line. If the line is shorter, the voltage wave can reach the termination and be reflected back to the junction while the traversal occurs. The effective damping will, then, depend also on the resistor.

Esteve *et al.* study the cross-over between the two situations and find a traversal time whose magnitude agrees with that predicted in refs 3–7. The experiment requires sophisticated subsidiary measurements to determine the circuit parameters, and the analysis includes a full treatment[17] of the frequency dependence of the circuit's response.

In most solid-state tunnelling situations, electrons, rather than the state of a whole circuit, are involved in the tunnelling. That leads to traversal times which relate to atomic distances and to typical electron velocities. These times are of the order of 10^{-14} or 10^{-15} seconds. The actual value found by Esteve *et al.*, 78 picoseconds, is remarkably long by comparison, which is why a mechanically variable transmission line, functioning on a similar timescale, can be used in the timing. □

PALAEONTOLOGY

Hearing in early mammals

Kenneth Kermack

CHANGES in the detailed anatomy of the ear are central to mammalian evolution, but most attention has been devoted to the middle ear. The inner ear is wholly enclosed within the petrosal bone of the skull and is consequently much less accessible. Serial sectioning of the petrosal is the ideal way of learning about the inner ear. Using this technique in a new study[1] of *Morganucodon watsoni*, from the early Jurassic, Graybeal and co-workers show that the hearing of this primitive mammal was much closer to that of birds and reptiles than to that of modern mammals.

In most vertebrates, the jaw hinge is formed from the quadrate in the skull and the articular in the lower jaw. In mammals, these two bones form part of the chain of three bones transmitting sound from the eardrum to the inner ear; the jaw joint is formed from two other bones, the squamosal in the skull and the dentary in the lower jaw. This unique squamosal–dentary jaw articulation is a diagnostic feature of mammals. *Morganucodon* had this joint between the squamosal and the dentary, but retained the older articulation between the quadrate and articular[2,3]: the two latter bones formed part of the jaw hinge as well as transmitting sound from the eardrum to the inner ear.

The hearing of mammals differs from that of other vertebrates in a manner that is often overlooked. The latter have an upper limit of frequency of about 10 kHz, the sensitivity of the ears even of owls declining rapidly above 12 kHz (ref. 4). Mammals are in a different league: the ears of the domestic cat are efficient at over 50 kHz, and even man, a poor performer among mammals, can better 15 kHz. This increased frequency range in modern mammals was made possible by two novel developments. The first is the separation of the mechanism for the conduction of sound from the jaw articulation: the middle-ear bones become much lighter and less constrained in mammals than in their immediate ancestors, and so conduct high-frequency sounds with greater efficiency. Second, the basilar membrane, which supports the organ of Corti (the actual sound receptor), becomes much longer. This is housed in a duct in the inner ear called the cochlea, so a long basilar membrane implies a long cochlea. In marsupials and placentals the cochlea is coiled up like a snail shell inside the petrosal. In living monotremes (the platypus and spiny echidna) the cochlea is shorter and curved rather than coiled.

Several petrosal bones have been preserved among the *Morganucodon* material from South Wales, including one

almost perfect specimen. The external features of the petrosal have been described in detail[5]. Graybeal and co-workers[1] sectioned four incomplete petrosals, traced the courses of nerves and blood vessels inside the bone and identified the openings at which these canals terminate with more certainty than is possible from inspecting the external surface of the bone alone. It is gratifying that they confirmed the existence of many of the canals and openings identified from the original description[5], although some of these had been lost on their less complete specimens. Graybeal *et al.* conclude that the relative length of the basilar membrane in *Morganucodon* resembled that of a bird or a modern reptile more closely than that of a modern mammal.

The obvious deduction from this is that the frequency response of the inner ear of *Morganucodon* was also much more like that of a reptile or a bird than a modern mammal. This was inevitable. *Morganucodon* stands right at the beginning of mammalian evolution: it is a mammal because the squamosal and dentary played a part in the jaw articulation, but the quadrate and articular had not been freed to become solely part of the sound transmitting mechanism of the middle ear, as in modern mammals. There is no use in having an inner ear capable of detecting high frequency sounds which the middle ear cannot transmit. □

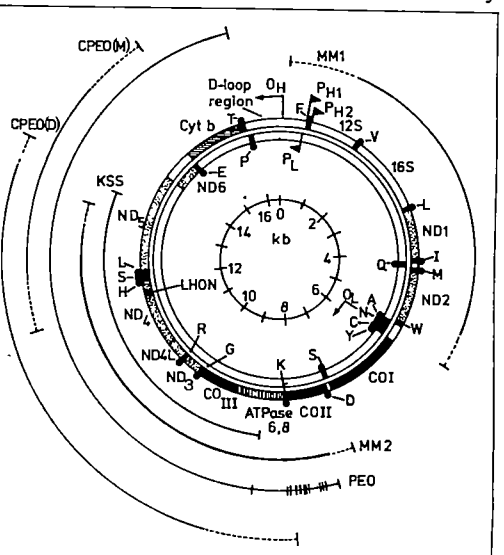
MITOCHONDRIAL DNA

Small, beautiful and essential

L.A. Grivell



HUMAN mitochondrial DNA (mtDNA) is remarkable both for its small size and for the immaculate economy of organization of the genes encoded by it[1]. Regarded by some as merely a relic of the event that brought a symbiotic bacterium into an ancestor of the eukaryotic cell, by others as a molecular biological curiosity for the ways in which conventional mechanisms are flouted during expression of its genes, and by yet others as a convenient marker for tracing recent evolution, mtDNA is now attracting attention for another reason. As a spate of recent reports demonstrate[2–8], a number of human neuromuscular diseases have structural abnormalities of mitochondria as their common feature and these appear to be caused by mutations in mtDNA. In some cases, the diseases, like mtDNA itself, are maternally inherited. In others, mutations appear to arise spontaneously during development, perhaps as the result of the action of a nuclear-gene product on the replication or recombination of the mtDNA molecule.

The biogenesis of a functional mitochondrion in all types of cells is a complex affair, with the information for most of the many hundreds of proteins required to construct the two membranes of the organelle coming from the nucleus (see ref. 9 for a recent review). Small though it is, human mtDNA makes an essential contribution to this process, as the figure indicates. The 16,596-base-pair molecule encodes the two structural RNAs of the mitochondrial ribosome, the 22 tRNAs required for mitochondrial protein synthesis and 13 proteins that, together with about 48 other proteins encoded by nuclear genes, make up the five multisubunit enzymes of the mitochondrial respiratory chain in the organelle's inner membrane (see also ref. 10).

One of the many unusual features of mtDNA in most organisms is its capacity for rapid change. In mammals, despite the extremely tight packing of information for gene products, the molecule fixes mutations 10–12 times faster than nuclear DNA[7]. The true rate of mutation is probably much higher, as many mitochondrial mutations occurring in the germ line may prevent formation of functional ova/spermatozoa, or the development of zygotes after fertilization. In somatic cells, the effects of potentially deleterious mutations may not be immediately obvious. Human cells normally contain thousands of mtDNA molecules and phenotypic expression will depend both on the extent of segregation of the mixed population of normal and mutant mtDNAs and on the cell's need for mitochondrial function. In this last respect, studies with respiratory inhibitors suggest that the tissues most likely to be affected are those of the brain and the central nervous system, followed by skeletal muscle, heart, kidney and liver[7].

In contrast to the ease with which mitochondrial dysfunction can be detected in lower eukaryotes such as yeast and *Neurospora*, diagnosis of mitochondrial diseases in man is far from straightforward. A mitochondrial myopathy is suspected if patients display impaired muscle oxidative metabolism, detectable by exercise stress testing, or ^{31}P-NMR, but a full diagnosis generally depends on examination of biopsy material. Histological examination of Gomori trichrome-stained muscle tissue may reveal fibres with a mottled or irregular appearance and red staining of peripheral or intermyofibrillar zones (ragged red fibres). Electron microscopy often shows numerous, enlarged mitochondria, containing whorled inner membranes and crystalline inclusions of protein in the matrix or intracristal spaces. However, unambiguous proof of dysfunction usually requires isolation of mitochondria, followed by direct measurement of respiratory chain function.

In terms of clinical presentation, perhaps one of the simplest types of mitochondrial disease is Lebers hereditary

Simplified clinical map of human mtDNA, showing mutations associated with the mitochondrial myopathies described in the text. Genes encoded by the heavy (H) and light (L) strands are shown on the outer and inner of the two circles, respectively tRNA genes are encircled and identified by their cognate amino acid, in the one-letter code. COI–III: genes for subunits I–III of cytochrome *c* oxidase ATPase 6,8: genes for subunits 6 and 8 of the mitochondrial ATPase ND1–6: genes for 6 subunits of the NADH dehydrogenase (complex I). Cytb: gene for cytochrome *b*. P_{H1} P_{H2} and P_L are promoters of transcription. O_H and O_L designate the origins of DNA replication for the two strands. LHON indicates the approximate position of the G to A substitution in the gene for ND4. Arcs represent the size and position of deletions found in various myopathies with stippled lines indicating regions of uncertainty. MM1, MM2 refer to the mitochondrial myopathies described in ref. 4; KSS to the Kearns–Sayres syndrome patients described in ref. 5, PEO to the progressive external ophthalmoplegia patients described in ref. 6, CPEO (M) and CPEO (D) to the mother and daughter with chronic progressive external ophthalmoplegia described in ref. 13.

optic neuropathy (LHON). The disease results in sudden loss of vision between adolescence and adulthood, due to death of the optic nerve. Affected relatives are invariably related through the maternal lineage. Using the polymerase chain reaction to facilitate analysis of segments of mtDNA from patients belonging to several different pedigrees, Wallace *et al.*[2] could show that each affected individual contains only a single type of mtDNA. Sequence analysis showed that a G to A transition, converting a highly conserved arginine residue to a histidine in the gene for subunit 4 of NADH dehydrogenase, was the only change that could be correlated with the presence of the disease in 33 individuals from 9 pedigrees. Although not yet formally proven, it seems reasonable to assume that this subtle missense mutation affects the efficiency of either electron flow or energy transduction through the enzyme, thus reducing ATP production enough within the optic nerve to cause premature cell death and blindness.

A more complex clinical picture is presented by patients with a maternally inherited mitochondrial encephalomyopathy that results in myoclonic epilepsy associated with ragged red fibres (MERRF). Patients display varying degrees of mitochondrial abnormality, as manifested by impaired muscle oxidative metabolism and reduced respiratory chain activity[3]. Generally speaking, the order of affected tissues is consistent with their reliance on mitochondrial function and the severity of the biochemical defects correlates with the severity of the symptoms. Molecular analysis of mtDNA, although excluding large deletions or insertions, has so far failed to pinpoint the change responsible. The wide range of clinical symptoms suggests, however, that the patients are in fact mosaics of wild type and mutant mtDNAs, the relative proportion of each type of molecule varying along the lineage, so determining the severity of the affliction. The disease is thus most probably caused by one or more deleterious mutations, that can only be maintained in the heteroplasmic state, in association with wild type mtDNA.

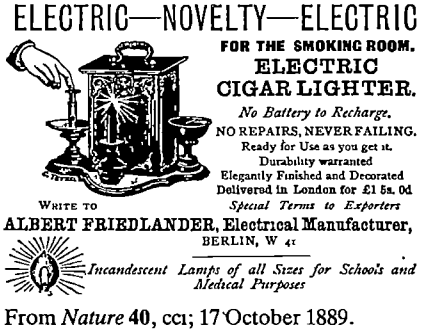
Heteroplasmy of mtDNA is a common feature of a number of other mitochondrial abnormalities associated with a wide range of neuromuscular diseases, including the Kearns–Sayres syndrome (KSS) and chronic progressive external ophthalmoplegia (CPEO). In these cases, patients' muscle tissue contains mtDNA molecules with large-scale deletions extending over several genes[4,5,8]. These mutant molecules are always mixed with normal mtDNAs and represent 20–90 per cent of the total number of molecules. Curiously, there is no obvious correlation between the severity of the clinical symptoms or biochemical abnormality and either the location of the deletion or the number of deleted genes. But as transcription of mtDNA generates polycistronic transcripts corresponding to the full length of each DNA strand, a major deletion anywhere in the genome may have serious consequences for expression of genes not covered by the deletion.

In contrast to LHON and MERRF, diseases associated with deleted mtDNAs have usually not been inherited. Usually, deleted molecules within the muscle fibres of an individual have the same structure, suggesting that they arise by the clonal amplification of a single spontaneous mutational event that probably took place at some stage during fetal development. The pleiotropic nature of these diseases, thus, is likely to depend on the relative proportion of normal and deleted mtDNAs in different organs. This view is supported by recent findings[11] that a deletion in mtDNA is the probable cause of a strikingly different human disease, namely Pearson's syndrome, a fatal disorder of the haemopoietic system.

Of interest for the mechanism of mutation is the fact that all deletions so far analysed in detail have their endpoints in short repeated sequences, which seem to be especially abundant in human mtDNA. One site in particular, consisting of direct repeats of 13 base pairs separated by approximately 5 kilobases, seems to be a hot spot for mutation. In a study of 30 patients with KSS or CPEO, 12 were found to have identical deletions with endpoints in a direct repeat of 13 base pairs, whereas an identical deletion is found in a patient suffering from Pearson's syndrome[11], suggesting that this site is a hotspot for mutation. Intramolecular homologous recombination or slipped mispairing during replication, which are both plausible mechanisms for generation of large deletions in other DNAs, may be a significant source of the deletions in these diseases, but neither explanation is really satisfactory.

First, there are no reports of any DNA-repair phenomena in animal mitochondria and orthodox recombination mechanisms appear to be absent[12]. Second, slippage mispairing, which depends on the generation of single-stranded regions in complementary strands carrying direct repeats, may not apply to animal mtDNAs, which are replicated from two origins, one on each strand, by a mechanism that is not expected to expose long stretches of complementary single-stranded DNA at any stage. But as Holt *et al.* have suggested[8], a discontinuous synthesis mechanism may operate during periods of rapid mtDNA replication, such as during oogenesis when many of the mutations may occur.

Also of interest in terms of mutational mechanisms is the finding[13] of a mother and daughter suffering from CPEO who possess mtDNA deletions of different sizes (2.5 and 5.0 kilobases). Thus, either the female germ line of this lineage contains two different deleted mtDNA molecules or, more likely in view of the complexity of interactions between nuclear and mitochondrial genomes during mitochondrial biogenesis, some other hereditary factor predisposes the mtDNAs of these patients to deletion.



Involvement of nuclear factors is also suggested by the results of a recent study[6] of an Italian family containing several individuals affected by a late-onset mitochondrial myopathy with symptoms similar to those of KSS. Like KSS and

DNA amplification

"The principles for extensive synthesis of the duplexed tRNA genes which emerge from the present work are the following. The DNA duplex would be denatured to form single strands. This denaturation step would be carried out in the presence of a sufficiently large excess of the two appropriate primers. Upon cooling, one would hope to obtain two structures, each containing the full length of the template strand appropriately complexed with the primer. DNA polymerase will be added to complete the process of repair replication. Two molecules of the original duplex should result. The whole cycle could be repeated, there being added every time a fresh dose of the enzyme. It is however, possible that upon cooling after denaturation of the DNA duplex, renaturation to form the original duplex would predominate over the template-primer complex formation. If this tendency could not be circumvented by adjusting the concentrations of the primers, clearly one would have to resort to the separation of the strands and then carry out repair replication. After every cycle of repair replication, the process of strand separation would have to be repeated. Experiments based on these lines of thought are in progress."

Members of the growing band of biomedical scientists who use PCR — the 'polymerase chain reaction' for amplifying specific DNA sequences, described by Kary Mullis and colleagues at the Cetus Corporation in 1985 — may like to dust off the *Journal of Molecular Biology* for 1971 (vol. 56, pages 341–361) and read a paper from H. Gobind Khorana and colleagues, the last paragraph of which is reprinted here. □

100 years ago

From *Nature* **40**, cci; 17 October 1889.

CPEO patients, these individuals are heteroplasmic, with the mutant mtDNA molecules containing large deletions whose boundaries lie in short repeated sequences. But, whereas KSS and CPEO arise sporadically, this particular disease is inherited. Moreover, it is inherited in an autosomal dominant fashion, suggesting that a mutation in a nuclear-coded protein may accelerate the accumulation of mitochondrial mutations. All deletions in these patients have their 5′-ends located close to the D-loop, a region of mtDNA that plays a crucial role in its replication and transcription, and hence is likely to be a site of important DNA–protein interactions. Strikingly, the deletions in different patients display different 3′-end-points, suggesting that the heteroplasmic mtDNA populations are not transmitted *per se*, but are generated *de novo* by a common mechanism.

What lessons can be learnt so far? The first is that the findings bring a unifying picture to a diverse group of human diseases. The concepts developed should simplify the diagnosis of even mildly affected individuals and they will probably allow the recognition of new forms of disease, whose origins lie in mitochondrial dysfunction. Of particular importance in this respect are late-onset degenerative diseases and possibly also those associated with ageing[14]. The high rate of mutation means that mtDNA will accumulate mutations during the whole life of an individual, thus giving rise to a range of cells with varying capacity for energy production and survival. The recognition of the mitochondrion as a common factor in such diseases should, however, also facilitate efforts at therapy. As initial promising results indicate (reviewed in ref. 10), it should be possible to counteract the effects of the mutations by stimulating cellular energy production by administration of cofactors and redox compounds. Finally, further study of those diseases in which gene expression in mitochondria is affected by changes in nuclear-encoded proteins should yield insight into the nature of the cross-talk between the two genetic systems that controls the biogenesis of this fascinating organelle. □

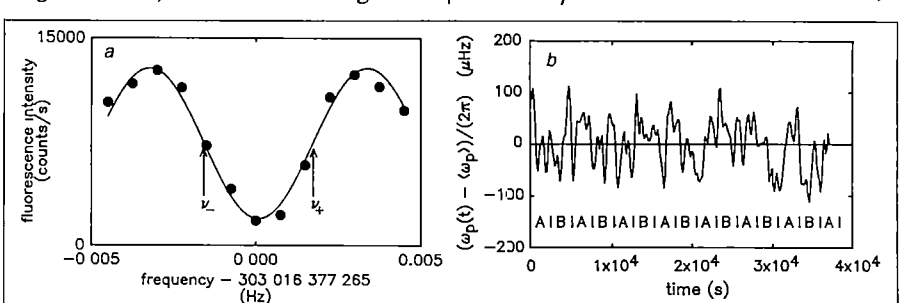
THEORETICAL PHYSICS

Is quantum mechanics linear ?

Richard Thompson

QUANTUM mechanics has been subjected over the years to many stringent tests, in which theoretical predictions for specific systems have been compared with experimental measurements to high precision. Really, however, these should be seen as tests of the accuracy of the hamiltonian equation, which describes a particular physical system, rather than of quantum mechanics itself. Earlier this year, Weinberg[1] suggested a way of testing whether nonlinear corrections to the framework of quantum mechanics are necessary. Applying his method to data from an ion-trap atomic-clock experiment at the National Institute of Standards and Technology (NIST) in Boulder, Colorado, he found a minuscule upper limit for any such corrections. The NIST researchers now report[2] a new experiment, based on Weinberg's approach, designed to reveal any nonlinearities; their upper limit is a further five orders of magnitude smaller than Weinberg's.



The existence of nonlinearities in quantum mechanics could have profound consequences for theoretical physics: the superposition principle, for example, could be vulnerable. Certainly, it is important that the very formalism of quantum mechanics should be tested.

The nonlinearity now being investigated is similar to that seen in all nonlinear oscillators for which the resonant frequency depends on the amplitude of the oscillations excited. A pendulum provides an example of such a system: as Galileo observed, for small oscillations the period is constant; but for large angular amplitudes, the period becomes longer. For a simple two-level quantum-mechanical system, the nonlinearity results in a change of the resonant frequency as the degree of excitation into the upper level is changed. A two-level system is equivalent to a spin one-half particle in an external magnetic field, for which the degree of excitation is related to the 'tipping angle' θ, which is the angle between the magnetic field and the spin. Here, $\theta=0$ corresponds to the pure ground state and $\theta=\pi$ to complete excitation into the upper state. Thus in this case, the precession frequency would not be constant, as predicted in linear quantum mechanics, but would be a function of θ

This nonlinearity should not be confused with that of, for example, a material which exhibits nonlinear optical phenomena at high light intensities. That system and its nonlinear response to light is described by (linear) quantum mechanics, depends on the material's properties and is well understood. Nonlinear quantum mechanics would result in transition frequencies that are a function of the degree of excitation of the system, showing some similarity with the predictions of earlier neoclassical theory reviewed by Mandel[3].

In his original paper[1], Weinberg showed that one weak driving frequency would not be able to drive the whole system from an initial (pure) state to the other state, because the system would become detuned during the process, owing to the nonlinearity. Only if this detuning were less than $1/t$, where t is the time taken for the excitation, would complete excitation be possible. Thus, if the complete transition is observed, this sets a limit on the nonlinearity present.

To understand Weinberg's approach, consider first the form of the standard Schrödinger equation used in quantum mechanics: $i\hbar d\psi/dt=H\psi$. The idea is to find a wavefunction ψ, which is a (possibly complicated) function of space and time, that satisfies the equation. H, the hamiltonian, depends on the interactions in the system — for example, the Coulomb attraction between the nucleus and electron in an atom — and the equation is linear in ψ. ▶

Search for nonlinearities. *a*, Ramsey signal of the 'clock' transition of $^9Be^+$ When the microwave pulses of the Ramsey probe are tuned to the precession frequency ω_p, the maximum number of ions are transferred from the ion's fluorescing state, so that the detected laser-induced fluorescence is minimized *b*, Be^+ precession frequency $\omega_p(t)$, referred to a passive hydrogen maser, as a function of time. The periods marked A (B) correspond to the tipping angles θ_A (θ_B) No systematic variation is discernible. (From ref 2)

Weinberg recasts this equation in such a way that H is a function of ψ and its complex conjugate ψ^*. The approaches are equivalent if H is linear in the product of ψ and ψ^*. With higher powers of ψ and ψ^* involved, the equation becomes nonlinear. Weinberg maintains certain conditions that apply to normal quantum mechanics in investigating the implications of the generalized equation: for example, the hamiltonian must be 'homogeneous' so that systems separated from one another are treated properly.

Although this formulation has been designed to add nonlinearity as generally as possible, it has been pointed out[4] that if the other postulates of quantum mechanics are left intact, it leads to violation of the second law of thermodynamics, which states that entropy always increases. Weinberg[5] replies that the definition of entropy used in ordinary quantum mechanics cannot be taken over into its nonlinear generalization, so a new definition must be sought. Thus, at present there does not appear to be any reason to exclude nonlinear corrections on theoretical grounds.

In general one would expect no more than a small nonlinear correction to the normal hamiltonian to arise — large corrections would have become apparent long ago. The most simple choice for the correction in the case of a spin-half particle in a magnetic field yields a precession frequency ω_p given by

$$\omega_p = \omega_0 - 4(\varepsilon/\hbar)\cos^2(\theta/2)$$

where θ is the tipping angle and ε measures the strength of the nonlinearity (ω_0 is the precession frequency normally predicted and $\hbar$ is Planck's constant).

The experimental system used for this investigation is a cloud of trapped and cooled beryllium ions[6], exposed to two coherent bursts of microwave radiation separated by a long period of free precession (the Ramsey technique; see the News pages for more on Ramsey's Nobel-prize winning work on atomic spectroscopy). The Penning ion trap, which uses a combination of static electric and magnetic fields to confine the ions to a small volume, contains of the order of 10,000 $^9Be^+$ ions. These are maintained at low temperatures (about 0.25 K) by collisions with roughly 100,000 $^{26}Mg^+$ ions held in the same trap. The ions are laser cooled (see my previous News and Views article[7]) by interaction with a laser beam tuned to a frequency just below their resonance line at 280 nm. Each time an ion absorbs a photon from the beam it slows down by an amount corresponding to the absorbed photon momentum until sub-kelvin temperatures are reached. The Be^+ ions are then cooled 'sympathetically' by the cold Mg^+ ions. The lifetime of the ions in the trap is essentially infinite as the whole system is maintained in an ultra-high vacuum (at pressures below 10^{-13} atmospheres).

The transition investigated is a nuclear spin flip in the Be^+ ions, which is field independent to first order at B=0.82 tesla and has a frequency of roughly 303 MHz. It is probed by irradiating the ion cloud with two coherent pulses (which would usually be $\pi/2$ pulses, changing θ by $\pi/2$ radians) separated by a period of the order of 100 seconds. It is only in an ion-trap experiment that such long interaction times and low temperatures can be achieved and this is what makes the measurement so sensitive. After irradiating the ions with the 303 MHz radiation, the number of ions to have made the transition is determined by measuring the population left in the initial state from the amount of fluorescence produced when the ions are irradiated by light at the Be^+ resonance wavelength of 313 nm.

The point of the experiment is to determine a difference in the precession frequency for different values of θ, so the first coherent pulse used in the Ramsey probe is chosen to give either $\theta=\theta_A=$ 1.02 radians or $\theta=\theta_B=2.12$ radians. Using a conventional feedback system, the probe oscillator is locked to the ion's precession frequency with $\theta=\theta_A$ for roughly 40 minutes, then with $\theta=\theta_B$ for 40 minutes and so on. A sample plot of this locked frequency against time is shown in the figure and does not show any clear oscillation between two values as θ is changed, as would be expected if the precession frequency were changing with θ in the manner predicted.

The accuracy of the experiment is limited by the frequency reference available and the detected frequency shift, which is consistent with zero, is 3.8 ± 8.3 μHz (the error corresponds to less than one complete cycle per day), yielding a value for ε of 1.8 ± 4.0 μHz. Thus the maximum possible value of ε is equivalent to an energy of 2.4×10^{-20} eV, or less than 4 parts in 10^{27} of the binding energy per nucleon of the beryllium nucleus. This limit is 10^5 times smaller than the previous one and can still be improved by roughly an order of magnitude with the present apparatus. Therefore, at the moment there is no reason to suppose that the framework of quantum mechanics shows nonlinearity at a significant level, though doubtless the search for such effects will continue. □

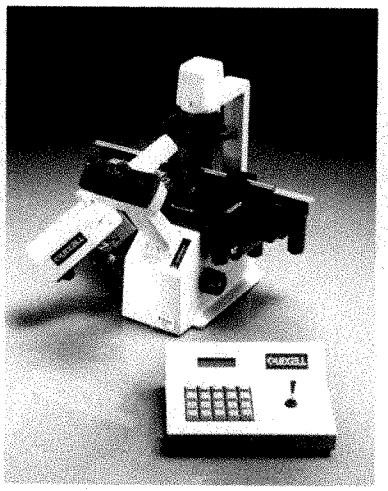
DAEDALUS

Stirrings of life

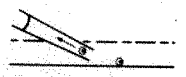
LAST WEEK Daedalus invented his circularly polarized microwave reactor. It spins the polar molecules in a solution, driving them along like little propellers if they have the right asymmetry. The slow, diffusion-limited kinetics of chemical reactions is thus vastly accelerated. The chemistry of life, dominated by polar chiral molecules, should be particularly speeded up.



DREADCO's botanists are therefore constructing a novel 'Microtational forcing house' for plants. A powerful circularly polarized microwave field should speed their growth tremendously. Provided with extra warmth, intense light, concentrated nutrients and a carbon-rich atmosphere to fuel their furious growth, they should hustle from seed to maturity in a mere few hours or days. Indeed, when perfected, the new forcing house may be best laid out as a conveyor-belt production line, with seeds being continuously set on the belt at one end of the building and harvested as fully grown plants as they emerge at the other. Agriculture should be wonderfully compressed in space and time, releasing vast tracts of land for airports, motorways, leisure centres, theme parks and other progressive amenities.

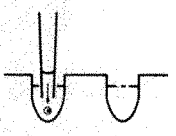
The biochemical effects of circularly polarized microwaves on human and animal growth should be equally dramatic, and DREADCO's biologists are exploring them cautiously. Animal growth and metabolism should be directly accelerated. Microtational pig sties, cow sheds and hen houses should bring livestock to rapid maturity without the problems and side effects of hormone treatment. Medicine may gain as well. DREADCO's microtational sick bay could well speed up the healing of wounds, the regrowth of lost hair or nails and the defeat of infection. (On the other hand, bacterial multiplication may be accelerated even more.) Impatient body builders should also welcome a microtational gymnasium.

More revolutionary still, a microtational pregnancy smock might deliver an accelerated baby in far less than the traditional nine months. But a microtational cradle or nursery, to speed its subsequent physical progress, could have grave drawbacks. The long drawn out human childhood has evolved to give the growing child time to absorb the vast amount of information it will need as an adult. And learning, like all mental activities, depends ultimately on the speed of neural transmission — an ionic process unaffected by circularly polarized microwaves. So an accelerated child would gain rapidly in stature, but not in wisdom. He would reach physical adulthood while mentally still very childish and backward. He might also be biologically that much older and would grow old and die before his chronological time. David Jones



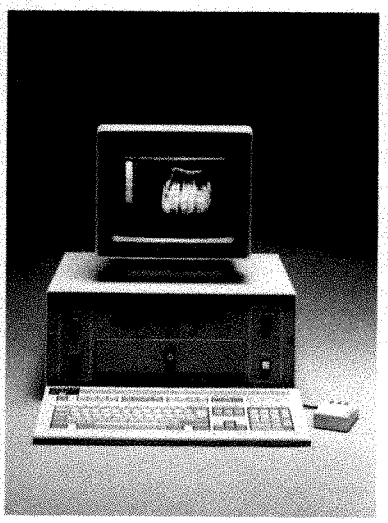
Introducing... QUIXELL CELL TRANSFER SYSTEM

► ***QUIXELL*** is a revolutionary new system for the rapid collection and transfer of individual cells, clones and other organisms from one vessel to another. The unique positive displacement micro pipette makes possible the controlled collection of a cell while remaining under full observation. a single collect/transfer operation takes only seconds allowing a microtiter tray to be rapidly seeded with individual cells. A wide range of pipette diameters are available to suit multiple applications.



The joystick control is used to guide a cell towards the tip of the pipette,

the cell is drawn into the pipette,



and a single keypress transfers the cell to a well in the microtiter tray. The system is now ready to collect the next cell.

Introducing... Autograph RADIO ISOTOPE IMAGING SYSTEM

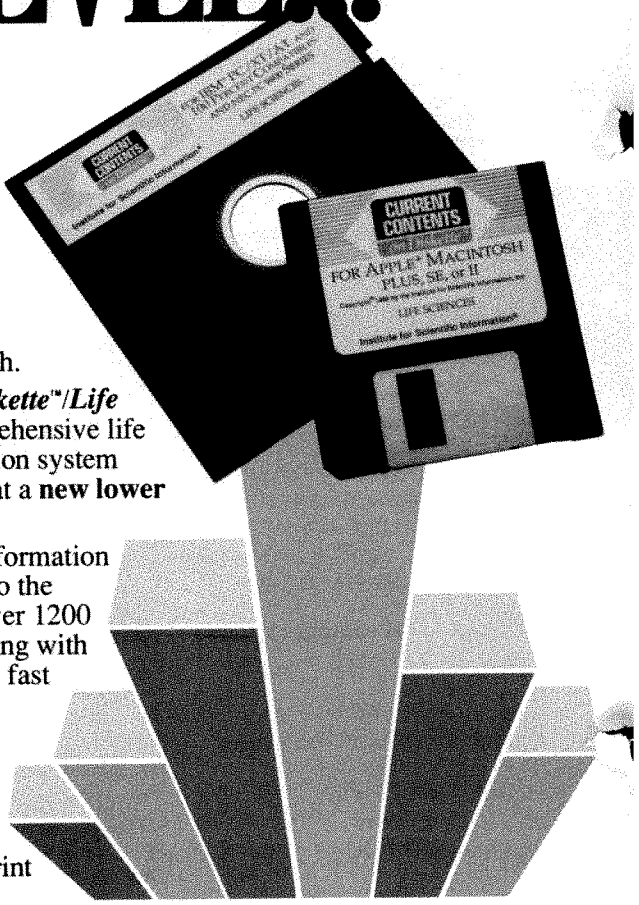
► ***AUTOGRAPH*** represents a breakthrough in digital imaging technology for the rapid evaluation of radio-isotope labels in chromatography gels, blots, tissue sections and similar samples.
The system is able to form an image at least fifty times faster than film thus providing conclusive experimental data in minutes rather than days or weeks. Extensive computer imaging software and display capabilities combined with extremely low background counts provide the capability of resolving many more 'shades of grey' than film making it possible to resolve even the weakest of radio-isotope concentrations.
All software is personal computer based and operates with a user friendly 'pull down' menu environment. Further applications software provides full quantification facilities for even the most complex images.

Developed and manufactured by Oxford Positron Systems Ltd.

Technical Specifications

- Live area : 210 mm x 210 mm
- Spatial Resolution : 1 mm
- Sensitivity :
  19 dpm in sq cm of ^{14}C in 6 min
  Background : 1.7 cpm per cm^2
- Chamber gas:
- Argon 95%, Carbon Dioxide 4%, Isobutane 1%
  Isotopes: ^{32}P ^{35}S ^{14}C ^{125}I. . . .

Software Specifications



- 256 colour display
- Simple user interface based on pull-down menus
- Continuous on-line image formation
- Scaling linear, log, automatic, or user defined
- Automatic user background correction
- Specimen Formats:
  Southern, Northern blots, Dot blots, Microtitre places, tissue sections, TLC plates. . . .
- 1-D or 2-D quantitation, displays and hard copy output
- User defined area, line and point quantification
- Further applications software available.

The protein assay of choice.

More researchers prefer the Bio-Rad protein concentration assay over all others, according to a recent survey. The main reasons are the sensitivity and reproducibility of this popular assay. Speed and convenience of the one-step Bio-Rad assay also rank high among users. In fact, more than 50 million Bio-Rad protein assays have been performed over the last 10 years.

The Bio-Rad protein assay has been cited thousands of times. For details on the assay, a free copy of our updated Applications Bibliography, and a copy of our Methods for Automation, contact:

There's nothing hard about our software.

System Gold,™ the Personal™ Chromatograph, teams an advanced HPLC system with a powerful personal computer* to make balancing many LC functions a lot easier.

The software is what makes it so easy. A mouse, drop down menus, truly helpful help screens and enhanced graphics give you the easiest control of your data ever.

All System Gold LC modules are fully programmable, and linked on a bi-directional digital network. So you control and monitor the entire system from a single point.

Superior integration algorithms always give you accurate, reproducible results. Stunning post-run graphics make data comparison and spectral analysis especially easy. Because of multi-tasking, you can even review data while the system is doing another run.

And it's easy to configure System Gold for any application — methods development, QC, analysis of amino acids, proteins, peptides and more.

Contact your Beckman HPLC Representative at 800/742-2345. Or Beckman Instruments, Inc., Altex Division, 2350 Camino Ramon, P.O. Box 5101, San Ramon, CA 94583. Offices in major cities worldwide.

There's nothing hard about it.

Olympus autofocus photomicrography takes the error out of focusing

What the naked eye perceives as sharp and clear often translates into a blurred image on film or paper.

Now Olympus brings you the Vanox-S—the world's first autofocus photomicroscope system—designed to eliminate focusing error in low magnification photomicrography (objectives from 1X to 10X), and ensure needle-sharp imagery throughout the entire magnification range. All you have to do is push the AF button.

And the Vanox-S also enables the use of two 35mm cameras and a large-format camera, incorporated into the body, together with automatic exposure and four photo eyepieces. Light intensity is adjusted with neutral density filters, maintaining color temperature consistency.

The new Vanox-S research photomicroscope system lets you reproduce the actual image you see accurately and with high quality. More easily and consistently than ever before.

Experience Magical Power

New Silver Staining kit
for Polyacrylamide Gel

Two dimentional electrophoresis (human serum)
2D · SDS-PAG PLATE 10/20 (code No. 120483)

It's fast and easy!

Easy 10 steps of procedure completes staining in just over 1 hour.

It's beautiful!

Proteins are stained evenly and uniformly while providing high contrast against clear background for improved resolution.

It's versatile!

Plastic or glass supported gels and IEF gels can also be stained just as beautiful as regular PAG plates.

It's free from overstaining!

You don't need to watch developing image every second. Yet, you will never overstain your gels.

It's

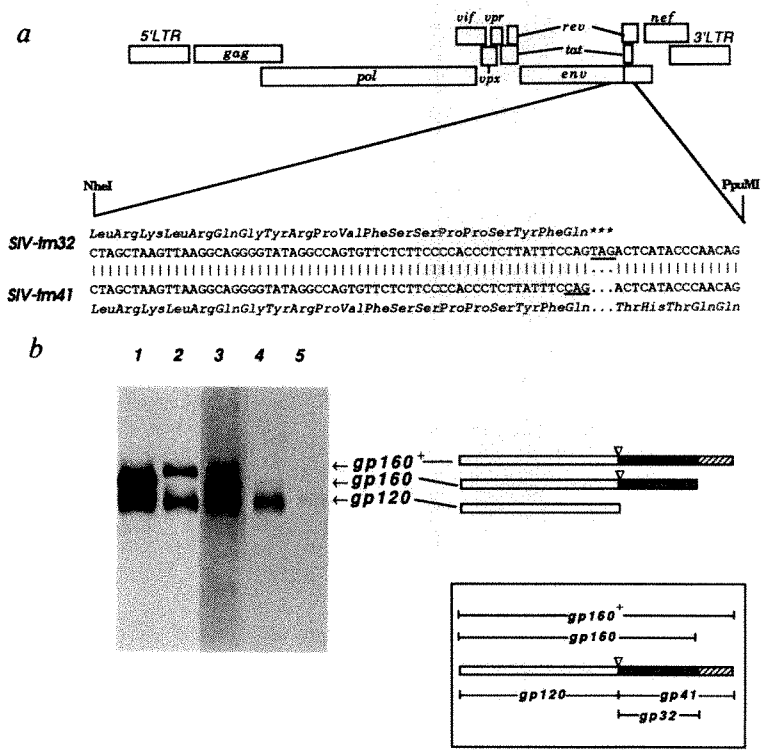
SIV adaption to human cells

SIR—Molecular cloning of simian immunodeficiency virus derived from rhesus macaques (SIV_{MAC}) has revealed[1-4] an in-frame stop codon in the envelope gene that truncates the cytoplasmic domain of the transmembrane glycoprotein relative to that of the human immunodeficiency virus HIV-1. As a result, SIV_{MAC} expresses a transmembrane glycoprotein of M_r 32,000 (gp32), rather than the 41K transmembrane glycoprotein of HIV-1 (gp41). We investigated the importance of the stop codon by removing it from an infectious molecular clone of SIV_{MAC} (pBK28; designated pSIV-tm32). Our findings indicate that this stop codon is an adaptation of a non-human primate lentivirus to growth in human cell lines.

We removed the stop codon from the *env* gene of pSIV-tm32 by replacing a 78-base-pair (bp) fragment with a synthetic 75-bp fragment that lacked the stop codon (see *a* in figure). This generated a clone designated pSIV-tm41. pSIV-tm32 and pSIV-tm41 were transfected in parallel into HUT-78 cells and equivalent amounts of reverse transcriptase activity were detected in culture supernatants 10 days later. Analyses of SIV-specific glycoproteins revealed the presence of an elongated *env* precursor (gp 160+) in cells transfected with pSIV-tm41, and a smaller gp160 in cells transfected with pSIV-tm32 (see *b* in figure). Transmembrane proteins of the predicted size were observed by western blot analysis.



Filtered supernatants derived from transfected cells were used to infect HUT-78 cells. Infectivity titres of these stocks in HUT-78 cells were 10^4 $TCID_{50}$ ml^{-1} for SIV-tm32 and $<10^1$ $TCID_{50}$ ml^{-1} for SIV-tm41. Paradoxically, both stocks appeared to have roughly equivalent amounts of virus particles as judged by reverse transcriptase activity and gag protein production. A persistent infection was established in only one of eight attempts to infect HUT-78 cells with cell-free SIV-tm41. This culture (referred to as SIV-tm41/32) produced gp160+, and also gp160 (see figure), as expected for SIV-tm32. To investigate this unusual finding, we used polymerase chain reaction (PCR) to amplify the region surrounding the original SIV-tm32 stop codon and determine the DNA sequence (see table). This analysis revealed a C → T point mutation in the CAG codon immediately preceeding the original stop codon, thereby regenerating a stop codon in some viral genomes in this culture. Selection of a stop codon mutant indicated that tm32 conferred a growth advantage to SIV in the human cell line, HUT 78.

The host range of SIV-tm32 and SIV-tm41 was evaluated in additional human cells (H9 and peripheral blood mononuclear cells (PBMC)) and rhesus macaque PBMC. SIV-tm41 grew preferentially in rhesus PBMC. By contrast, SIV-tm32 was stably propagated in human cells. PCR analysis of SIV-tm32-infected rhesus PBMC revealed mutants lacking the stop codon by day 17 (see table). Thus, forms of the SIV transmembrane glycoprotein are selected based on the host cells used for virus propagation; an extended glycoprotein is preferred in rhesus PBMC and a truncated one in human cells.

We next sought to determine which transmembrane glycoprotein structure(s) are present in SIV-infected macaques. Four rhesus macaques were inoculated with SIV-tm32 or the SIV-tm41/32 virus mixture described above. All animals became persistently infected. Genomic DNAs from PBMC collected 10 months post-inoculation were analysed by PCR for stop codons (see table). Regardless of the original inoculum, the dominant genotype detected in circulating PBMC was SIV-tm41. By contrast, co-cultivation of human cells with PBMC from one infected macaque resulted in re-selection of the SIV-tm32 genotype. Thus, tm41 is the naturally occurring form of the SIV_{MAC} transmembrane glycoprotein in infected macaques. This conclusion is consistent with the observation that SIV-infected macaques have antibodies reactive to synthetic peptides derived from the region C-terminal to the stop codon of the transmembrane protein[5].

We have observed a similar conversion from a 41K to a 32K transmembrane glycoprotein in human cells (H9) transfected with a molecular clone of SIV from sooty mangabeys (SIV_{SM}), an African SIV closely related to SIV_{MAC}[6]. This conversion was due to an out-of-frame duplication (130 bp) in the region of the stop-codon in SIV_{MAC}. Truncation of the transmembrane glycoprotein has also been observed in SIV from African green monkeys SIV_{AGM}[7], and in HIV-2[8,9]. The form of transmembrane glycoprotein genes in SIV_{AGM} or HIV-2 infected individuals has not been determined. Similarly located stop codons have not been observed in HIV-1 clones. Furthermore, deliberate truncation of the HIV-1 glycoprotein in an analogous position seems to destroy its infectivity for HUT-78 cells (data not shown).

The cytoplasmic domain of viral envelope proteins has been implicated in virus assembly, cytopathic effects, and *env* protein transport to the cell surface[10-14]. We have not identified the biochemical basis for the selective growth characteristics of SIV with differing length *env* cytoplasmic domains. However, apparent levels of SIV-tm41 *env* glycoproteins in

a, Construction of SIV-tm 41. A map of open reading frames of the SIV genome is shown. The nucleotide and deduced amino-acid sequences of the synthetic restriction fragment used to remove the SIV-tm32 stop codon is shown below, aligned with the sequence of the original clone pSIV-tm32. pSIV-tm41 was constructed by ligation of a synthetic oligonucleotide lacking the stop codon into pSIV-tm32. *b*, Analysis of SIV glycoproteins. The env proteins of SIV-tm32 (lane 1), SIV-tm41 (lane 2), and the SIV-tm41/tm32 revertant virus mixture (lane 3) are shown following lentil lectin affinity purification and radioimmunoprecipitation[18]. Extracellular glycoprotein (gp120) of SIV-tm32 (lane 4) and SIV-tm41 (lane 5, faint band on this exposure) from purified virions are indicated. A diagram indicating the derivation of these proteins is also shown.

human cells are reduced relative to other viral proteins (data not shown), indicating that impaired replication of this virus in human cells may be the result of decreased stable *env* glycoprotein expression.

Our findings demonstrate that SIV_{MAC} genomes encoding a truncated transmembrane protein are selected by their ability to grow in human cells in culture. Thus, *in vitro* propagation may select for mutant forms of virus, skew the representation of genotypes within a virus mixture, and obscure the full potential of viral genomes by altering open reading frames. Tissue culture adaptation could conceivably select against AIDS pathogens (both SIV and HIV) by fortuitious host cell selection, defective replication, or differential cytopathic effects. For example, feline and murine leukaemia retroviruses which causes AIDS-like diseases in cats and mice, respectively, are replication defective. However, their closely related but minimially pathogenic helper viruses are replication competent[15–17]. In addition, less cytopathic viruses may predominate in surviving cells as highly cytopathic variants kill their host cell more efficiently. This report highlights the problems inherent in studying complicated host–pathogen relationships in tissue culture systems. The SIV-tm32/41 adaptation we described here does not appear to effect pathogenicity. However, molecular clones of SIV derived from tissue-culture-adapted virus are minimally pathogenic in macaques. Thus, functional analysis of viral genomes derived directly from tissues will be necessary to explore fully the pathogenic spectrum of AIDS viruses.

Genotypic changes in the SIV *env* gene following propagation in cell culture and *in vivo*

Viral DNA sequences surrounding the original stop codon were amplified by PCR from infected cells in culture or uncultured PBMC, cloned and their DNA sequence determined. The percentage of the genotypes defined by the presence or absence of a stop codon (underlined) and the number of clones analysed (in parentheses) are indicated. Viral DNA sequences were amplifed from 1 μg cellular DNA during 35 heating–cooling–extension cycles (94 °C for 45s, 55 °C for 1 min, 72 °C for 1 min) in a Cetus-Perkin Elmer thermal cycler. Each 0.1-ml reaction contained 50 mM KCl, 10 mM Tris-HCl, pH 8.3, 0.01% gelatin, 200 μM each of all four deoxynucleotide trisphosphates, 2mM $MgCl_2$, 2.5 U *Thermus aquaticus* polymerase (Cetus-Perkin Elmer), and 10 pmol of oligonucleotide primers. Samples (10 μl) from PBMC were reamplified in fresh reaction buffer for an additional 35 rounds with an internal, or 'nested' set of primers containing restriction sites at their 5° ends to facilitate later cloning. Products were cloned into either m13mp18 or pUC18 and sequenced using T7 DNA polymerase.

Too many leucine zippers?

SIR—The leucine zipper was first proposed[1] as a hypothetical structure facilitating dimer formation of the nuclear proteins C/EBP, Fos, Myc, Jun and GCN4. Its characteristic motif is a periodic repeat of leucines at every seventh position (a heptad repeat) in a segment of 22–29 residues, and its overall composition (in particular, the absence of prolines and glycines, and a high density of ion pairs) is compatible with α-helical secondary structure, suggesting that dimerization is based upon coiled coil interactions[1,2]. However, a distinction has been made between the leucine zipper and the coiled coil interfaces in fibrillar proteins like tropomyosin, keratin and lamins on the basis of the almost exclusive use of leucines in the $i+7$th positions and the non-conservation of hydrophobic residues in the $i+4$th positions (in Fos and Myc)[3]. More recently, it has been claimed that many other proteins contain the leucine zipper motif, including the fusion glycoproteins of paramyxoviruses[4], voltage- and ligand-gated ion channels[5] and glucose-transporter glycoproteins[6]. Note, however, that unlike the situation in C/EBP, the motif in the paramyxoviruses entails predominantly charged and uncharged polar residues in the $i+4$th positions, and the motif in the glucose-transporter proteins entails two

substitutions of isoleucine for leucine.

We wish to caution against the too ready acceptance of the significance of leucine heptad repeats found in databank searches. In particular, we address the following questions concerned with the statistical background of such searches. How many leucine heptad repeats might one expect to find merely by virtue of chance? Are leucine heptad repeats relatively more frequent in proteins than heptad repeats of other amino acids (taking into account the biases in residue composition)? Are heptad repeats of leucine more frequent than repeats of other period length?

In the table we list the probability of occurrence of 4 or 5 leucine repeats in random protein sequences of given size and leucine content. Natural protein sequences are not random, but the tabulated probability values may serve as a reference in estimating the statistical significance of the observed repeats. It is seen, for example, that 4 repeats in a 300–500 residue sequence of average leucine content (10%) occur with only 3–4% probability, but that this probability is considerably increased for sequences of higher leucine content or greater length.

We have screened in excess of 450 distinct mammalian proteins of mean length 450 residues and average leucine content 9.7% for occurrences of the motif L-X_6-L-X_6-L-X_6-L, where L is leucine and X is any other amino acid. The motif is found in more than 30 of the sequences, but in only about half of them, including ribophorin I, spectrin and interleukin-3, is X never a proline. Heptad repeats of other amino acids occur much less than half as frequently as the leucine heptads, in agreement with the fact that leucine is by far the most common amino acid over all the proteins analysed. The second most frequent heptad repeat (occurring more than five times as often as expected) contains glutamic acid residues instead of leucine (as, for example, in the $i+3$th positions of the Fos leucine zipper).

Probability of observing a success run of r periodically repeated leucines in a sequence of length n for a given frequency f of leucine in the sequence.

	$r = 4$			$r = 5$		
n/f	6.5%	10.0%	13.5%	6.5%	10.0%	13.5%
200	0.003	0.02	0.06	0.001	0.002	0.008
300	0.005	0.03	0.08	0.001	0.003	0.01
500	0.008	0.04	0.13	0.001	0.004	0.02
1000	0.02	0.09	0.25	0.001	0.009	0.04

The probability is closely approximated by $(1 - fx)/[(r + 1 - rx)(1-f)x^{n+1}]$, where x solves $(1 - f)x(1 + fx + .. + f^{r-1}x^{r-1}) = 1$ (ref. 7). A lower bound for the probability of observing an r-repeat of any (not predetermined) amino acid is given by the same formula with values $r - 1$ and $f = 5\%$ (0.03–0.06 for $r = 4$ and $n =$ 300–500).

For the same set of proteins, leucine repeats of length 4 with spacing 5 or 7 (rather than 6) are found in about 20 proteins each. Also, spacings 3 and 6 are preferred over spacings 4,5,7 and 8 between (not necessarily nearest) neighbouring leucines. This relative excess of leucine heptad repeats is consistent with the role of leucines in establishing hydrophobic faces of α-helices, including those involved in coiled coil interactions. Interestingly, the same preference for spacing 6 holds for glutamic acid residues, possibly reflecting their role in establishing hydrophilic faces of α-helices.

Thus the leucine repeat by itself occurs widely on both probabilistic and empirical grounds. This abundance undoubtedly reflects the particular structural role of the motif but it also warrants a cautioning note with respect to the prolific citation of leucine zippers, particularly when pattern searches allow for substitutions in the leucine positions. While one might rightly want to accommodate true variations in primary sequence yielding equivalent three-dimensional structures, attention ought to be given to the concomitant increase in the level of false positive occurrences. Based on our probability estimates and data work, we think that perhaps as many as two of every three leucine zipper motifs are simply chance occurrences.

Moving proteins

SIR—The use of Con A labelled with 40-nm gold particles to show forward movement of membrane glycoproteins in locomotor cells[1] is exciting, but it should not be forgotten that during the past decade, several groups in the leukocyte chemotaxis field have reported forward distribution of cell-surface receptors in polarized and actively moving leukocytes, albeit using less refined techniques. Many workers have considered that this distribution is the result of an anterior movement of membrane proteins rather than their reinsertion at the leading edge.

Anterior distribution has been reported for Fc receptors[2-4] and for receptors for a chemoattractant peptide[5]. A variety of functionally unrelated proteins, including Thy-1 (ref. 4) and CD45 (ref. 6) also show forward distribution on locomotor lymphocytes. This anterior distribution is independent of the ligand used to stimulate polarization and locomotion, and occurs rapidly[7]. We have suggested[8] that forward movement of chemotaxis receptors is an intrinsic component of chemoattractant-induced polarization, that it is intrinsic to the directional locomotor response, reinforcing the persistence of that response in cells moving up a gradient, and that it also accounts for the long stretches of persistent locomotion in a given direction seen in cells moving randomly when the chemoattractant is uniformly distributed.

A question remains about mechanism. Kucik *et al.* discuss myosin I which is linked to both actin and to membrane sites, as a possible motor. However, Thy-1, a protein which is inserted by a phosphatidyl-linkage into the outer leaflet of the lipid bilayer, nevertheless moves forward and maintains an anterior distribution in motile lymphocytes, indicating that linkage of cytoskeleton to forward-moving proteins may be indirect.

SIR—Kucik *et al.*[1] state that "no forward transport of particles has previously been reported" on locomoting cells and, again, that "only rearward transport of surface particles had been observed". This is not the case. As detailed in my recent review[2] of the entire literature on the use of inert particles as markers for cell surface membrane dynamics during cell motility, workers have observed the forward movement of inert marker particles (carmine, India ink, carbon particles) along the surface of locomoting freshwater amoebae.

Mass loss in PSR 1957+20

SIR—Although the precise mechanism of the eclipses in the binary system containing pulsar PSR 1957+20 is still unclear[1-5], it is generally agreed[1-4] that the $\sim 0.02M_{\odot}$ companion[1] in circular orbit ($e < 0.0002$) (ref. 2) is losing mass. Measurement of the mass-loss rate of this very light companion can provide a critical test of theories of this millisecond pulsar as well as the theory of millisecond pulsar evolution[3,4,6,7]. As pointed out by Kluźniak *et al.*[3], the mass loss need not lead to a significant change of the orbital period, P_{orb}, if the ratio of the specific angular momentum lost to the specific angular momentum of the companion star, k, is close to unity, because

$$\dot{P}_{orb}/P_{orb} = 2(k-1)\dot{m}/m_c \qquad (1)$$

where m_c is the mass of the companion. Here we point out that if the change in speed of the neutron star, v_1, another observable quantity, were measured, then the mass-loss rate could be deduced as

$$\frac{\dot{m}_c}{m_c} = \frac{\dot{v}_1}{v_1} + \frac{1}{3}\frac{\dot{P}_{orb}}{P_{orb}} = \frac{\dot{a}_1}{a_1} - \frac{2}{3}\frac{\dot{P}_{orb}}{P_{orb}} \qquad (2)$$

where a is the semimajor axis.

Equation (2) is model independent. Therefore, observational determination of mass-loss rate can be made by measuring v_1 and P_{orb} as well as their time derivatives.

From theoretical arguments, if the evaporation of the companion is fast enough to explain the original solitary millisecond pulsar PSR 1937+214, $m_c/\dot{m}_c < 10^8$ yr is needed. Six months of data on PSR 1957+20 gives $3P_{orb}/\dot{P}_{orb} > 10^7$ yr (ref. 2), while $v_1/\dot{v}_1$ is easily measured from the Doppler shift of the pulse period. Within five years, we would probably reach the limit of theoretical interest even if $\dot{P}_{orb}/P_{orb}$ is the dominant term.

Kinematics of the Alpine arc

SIR—Platt *et al.*[1] provide a compilation of kinematic data for the Alpine arc which will find far wider use than their particular purpose of establishing the independence of the Adria plate from both the European and African plates. They stress that "we have included only data for which we could find good evidence of age". Their ages are out of date, however, in that they have not taken account of some recent research or of changes in stratigraphic correlations. This is most clearly the case in the south-west Alps, where they have allocated all their south-west-directed motions in the external zones and in the nappes of Embrunais–Ubaye (their arrows 37,40,45,46,47,49–51) to ages that are post-Eocene.

A principally sedimentological study[2] in an area between the Embrunais–Ubaye nappes and the Provençale platform found south-west-directed thrusts that had cut the surface during deposition of calcaire nummulitique (Eocene). The study shows that south-west-directed thrusting constrains the geometry of the Grès d'Annot basin (Eocene). Most thrusts in the upper parts of the external zone succession, and many in the sub-Briançonnais of the lower Embrunais–Ubaye nappes[3] are folded by structures that formed during nappe emplacement[3,4]. The hypothesis that the nappe loading caused the thrusts in the external zone beneath and which has generally been accepted as a basis for structural correlation, is therefore not valid and an earlier (Eocene) age for much of the thrusting is established.

It is also necessary to reinterpret ages in the literature. Many biostratigraphic zones were once considered of Oligocene age, but are now firmly established as Eocene (see ref. 5, for example). Whereas the shift of the zonal scheme has been 'absorbed' relativly easily, many early attributions of Oligocene age to structural events persist in the structural geology literature. The emplacement of the lower Embrunais–Ubaye nappes is important in structural correlation and is well constrained stratigraphically.

Referring to the nannoplanktonic (NP) zonal scheme, the topmost beds of the Grès d'Annot are NP 19–20 (Muller, cited in ref. 5). The nappes override these beds, after deposition of an olistostrome[6], but were uplifted, subjected to subaerial erosion, and become the source of the sediment near the base of zone NP 22 at Barrême[7]. Emplacement was therefore within a time window corresponding to zones NP 20 and NP 21. If we now accept the zonal boundary NP 21–22 as the Eocene/Oligocene boundary (as for example p. 393 of ref. 5), the nappe emplacement and all associated structures must be of Eocene, not Oligocene, age.

The pitfalls of structural correlation in the Embrunais–Ubaye region are discussed elsewhere[8]. Readers of Platt *et al.*[1] are advised that these amended ages do not invalidate the general time-divisions of their Figs 1 and 2 but that, in the south-west Alps and possibly elsewhere, some of the data which they have treated as post-Eocene may be of Eocene age. In any event, their data set is misleading in that it does not indicate the scale and complexity of Eocene Alpine tectonics which, in the south-west Alps at least, was dominated by southwestward displacements[8].

NORMAN FRY

Cardiff CF1 3YE, UK

PLATT REPLIES—The evidence cited by Fry (unpublished when we wrote our paper[1]) for a late Eocene onset of deformation in the external zone of the south-west Alps is of considerable interest, as precise timing of the beginning of deformation in different parts of the Alps should help constrain the rate of convergence. The main evolution of the thrust belt in this region, however, is clearly post-Eocene: Grès d'Annot and flysch of Priabonian (late Eocene) age are imbricated in the thrust sheets; and in the Digne and Nice arcs, Triassic rocks have been thrust over sediments of late Miocene to Pliocene age.

The presence of detritus derived from the Embrunais–Ubaye nappes in late Eocene sediments is not a valid constraint on the timing of external-zone deformation. These nappes, which form part of the internal zone, had been incorporated into the Alpine orogenic wedge and could have been subject to erosion by late Eocene time: kinematic data reflecting this deformation are shown on our map (data sets 41, 42 and 44 in Fig. 1 of ref. 1) and generally trend west or north-west. The accretion of external-zone rocks beneath these nappes occurred later and caused folding, reimbrication and back-thrusting in the older parts of the wedge (data sets 43, 45 and 46): these structures are generally associated with north-east–south-west-directed kinematic indicators parallel to those associated with the co-eval south-west-directed thrusting in the external zones (data sets 37, 47 and 49).

THE BEST SEAT FOR THE LATEST DEVELOPMENTS

EMBASE - a biomedical and pharmacological database – gives you access to the most up-to-date information about medical and drug-related subjects. Our medical specialists select and index articles from over 3,500 international biomedical journals.

The indexed citations, most of which have abstracts, are entered into the EMBASE database. The throughput time for this process is less than 30 days. EMBASE provides you with the most current data available.

EMBASE is managed by Excerpta Medica, a division of Elsevier Science Publishers, an internationally respected publisher. This is your guarantee that the information supplied is selected with care and professionally processed. Every year, 300,000 new citations are added to EMBASE. The database now contains over 3.5 million records.

You can directly benefit by using this up-to-date and extensive database. Just access EMBASE via the usual online information retrieval systems, which are updated weekly. The staff of EMBASE also provides all the support you need to ensure maximum benefit from your use of the database.

Would you like to be in the best seat? Then fill in the coupon immediately and send it to Excerpta Medica. We will send you more information or contact you to make an appointment for a demonstration.

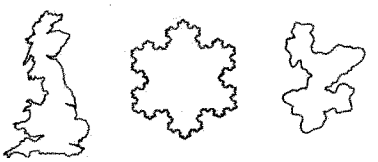
More info in less time

1988. XIV, 337 pages with 8 figures and 8 tables. Hardcover. DM 68.00. ISBN 3-527-26863-4

This book explores the problem-solving potential of True BASIC (Version 2.0), an entirely newly structured version of BASIC. True BASIC retains all the simplicity of the earliest versions of BASIC and has superb machine-independet graphics, making it arguably the best high-level language for beginners. True BASIC also has features which will be quite unrecognizable to old-time BASIC addicts: modern control structures, named subroutines with arguments and local variables, modules, pictures (graphics subroutines) and so on. These features enable it to take its place as a serious scientific problem-solving language of the first degree.
The book can be used as a "teach yourself" guide.

1989. XII, 714 pages with 46 figures and 25 tables. DM 98.00.
ISBN 3-527-27807-9



This versatile introduction to the application of (personal) computers in chemical research activities presents mathematical solutions and sample programs for a large number of common chemical and physical problems. Computer graphics, the use of PCs in modelling and simulation studies, and data processing are also treated.
Special feature: Enclosed are two diskettes (in ASCII code) which contain all the programms given in the book in both BASIC and PASCAL. The diskettes are suitable for all IBM-conpatible PCs.

A Random Walk Through Fractal Dimensions

1989. XXVI, 421 pages with 316 figures. Hardcover. £ 49.45. ISBN 3-527-26468-X.
Softcover. £ 22.95. ISBN 3-527-27876-1

Fractal geometry is revolutionizing the descriptive mathematics of applied materials systems. If you have been intrigued by the pictures of fractal systems that have appeared in the scientific literature, this book will enable you to discover where you can apply fractal systems in your work.
Written from a practical point of view, it avoids the use of equations but is richly illustrated with graphic examples. You thus gain an appreciation of the importance of fractal systems without being swamped by symbols.
The book is also useful as a first text for students. It contains enough suggestions for experiments to keep an army of research students working for the next ten years.

The sublime and synaptic

John C. Marshall

Beauty and the Brain: Biological Aspects of Aesthetics. Edited by Ingo Rentschler, Barbara Herzberger and David Epstein. *Birkhäuser: 1988. Pp.325. SwFr.68.*

THEODOR Adorno's last book (*Aesthetic Theory*, 1970) opens with the line: "Today it goes without saying that nothing concerning art goes without saying". One should not, then, be unprepared for the existence of a volume with the subtitle *Biological Aspects of Aesthetics*.

No human culture is devoid of music and dance, the visual arts, poetry and story-telling. All normal children stomp unprompted to the band, scribble on the walls or doodle in the sand; devoted to our doggerel din, they demand the selfsame story 'til their parents' imperfect patience wears exceeding thin. No obvious utilitarian value attaches to such phenomena. The notion that the young are merely exercising their muscles and memories lacks conviction; the pleasure seems to be genuinely 'aesthetic' (although one might be hard pressed to provide rigorous corroboration) and intrinsic to our species.

In the rest of the animal world parallels are not easy to find. In Chapter 2 of *Beauty and the Brain*, Eibl-Eibesfeld mentions the 'tachist' paintings of Desmond Morris's chimpanzees and some interesting experiments (by Rensch) on monkeys, raccoons and birds. These latter studies in which the animals apparently showed preferences for symmetry and regularity are not sufficiently elaborated upon. It is true, of course, that birds sing, frogs croak and beavers build; bees prefer bright colours and primates beat their breasts. But these behaviours have a solid biological function; the attraction of mates or the repulsion of enemies; the provision of appropriate food and shelter.

To credit other creatures with the capacity for aesthetic response is superfluous to Occam's razor. As far as we know, no Prince Charles of the spider-kingdom waves its legs in horror at the design of modern webs; no rodent that eats the green berries whilst avoiding the (poisonous) red ones would nonetheless collect the latter on the grounds of aesthetic superiority. Louder croakers may acquire fatter mates, but there is no firm evidence that painting abstract pictures for 12 hours a day will necessarily secure one a more attractive spouse (or pay the rent).

It is thus tempting to propose that the aesthetic sense is a distinct faculty of mind, represented physically in a dedicated brain-module; an autonomous, species-specific organ characterized by rule-governed creativity, the free play of which is engaged in for its own sake. This position is not dissimilar to current views of the organ of language, and is equally likely to produce apoplexy in those evolutionists who believe (as an article of faith) that all differences between related species are solely incremental. I exaggerate, of course, but not much. Indeed, Gregor Paul, one of the contributors to *Beauty and the Brain*, writes: ". . . if Chomsky's hypothesis that there exists a universal grammar is acceptable, then a similar hypothesis concerning universal aesthetic rules is even more convincing". Sadly, he does not develop this argument to the extent of telling us why Schönberg's fervent desire to be regarded as a high-class Tchaikovsky has not (yet) been fulfilled.

Beauty and the Brain derives from a series of symposia that took place in Bad Homburg between 1979 and 1983. The participants — "a group of neuroscientists, psychologists, anthropologists, philosophers, artists, musicians, and a poet" — met the magic number of seven times to lay the foundations for "the emerging field of *neuroaesthetics*". The book that has resulted from these deliberations is fascinating but very patchy.

As might be expected, the notion of hemispheric specialization looms large (although it is odd that the biological significance of artistic prodigies, either *idiots savants* or 'normal', is nowhere discussed). Regard and Landis show that preference judgements between simple forms differ as a function of the cerebral hemisphere to which the material is projected; Levy suggests that musicians and painters "have an unusual degree of bilateral representation of artistic skills, which permits superior interhemispheric integration". Grüsser, Selke and Zynda add a historical dimension by analysing the head position of 933 portraits from the fifteenth to the twentieth century; a distinct preference for showing the left side gradually decreases over the centuries. These chapters are not uninteresting although somewhat unbalanced. Data in search of theory or vice-versa is a general characteristic of the volume.

Thus Turner and Pöppel discuss metered poetry, to little artistic effect. They point out that two sounds must be (minimally) 0.03 seconds apart before their sequence can be perceived, that syllables are (typically) 0.3 seconds in duration, and that 3 seconds is "the length of the human present moment". But their account of meter is trivial and poorly integrated with their calculations: ". . . poetic meter serves a number of functions generally aimed at tuning up and enhancing the performance of the brain". Enhancing it for what? Epstein shows that across many

Notes for the aesthete — the first page of the autograph score of Mozart's *Eine Kleine Nachtmusik*, written in 1787. In some eyes, the score has a beauty of its own; some people, apparently, also enjoy the music when played.

cultures from Tibet to the Kalahari (via New Guinea and Venezuela) "tempos in musical performance change by low-order integral ratios". Both the biological and the aesthetic significance of the observation remain opaque. Siegfried analyses the space–time structure of the grasshopper dance performed by !ko-Bushmen. The pulse beat (indexed by the deepest flexion of the knees) is remarkably stable across extremely complex movement patterns but the author's interpretation is sloppy: "The rules provide a framework within which the dancer can cause shivers by trying new exciting movement combinations". You should see me do the tango!

The visual arts suffer much the same fate. Zollinger provides a good introduction to colour perception and naming, while Baumgartner writes lucidly on form perception. But neither explicitly relates the modular character of the visual system to the pictorial effects that can be manipulated in drawing and painting. The sole chapter that does make an effort to do so is by Rentschler, Caelli and Maffei. They demonstrate how reducing image information by band-pass and orientation-selective filtering can simulate the look of a Monet or a Feininger, or soften a Duccio into a Leonardo.

We now have a general model of the psychophysiology of the visual system: separate pathways for colour, different aspects of static form perception, and movement and depth, that are integrated into a unified percept. But why should (some ways of) de-unifying that percept by selectively enhancing, attenuating or distorting components of the *gestalt* produce interest, insight and pure pleasure? The editors of *Beauty and the Brain* did not invite "a recognized specialist in the field of art history or aesthetics" to their symposium. Future meetings may need to include contributions from those areas if neuroaesthetics is ever to replace the theory of the nine Muses. When actually listening to Mozart it is difficult not to feel that God decided to amuse herself by dictating a few piano concertos. And that choosing Amadeus as amanuensis was the best joke of all. □

On the road to Montreal

Philippa Lloyd

Ozone Crisis: The 15-Year Evolution of a Sudden Global Emergency. By Sharon L. Roan. *Wiley: 1989. Pp. 270. $18.95, £12.95.*

ONCE thought of as 'dream' compounds because of their chemical stability and lack of toxicity, chlorofluorocarbons (CFCs) first came under suspicion in 1974. In a paper published that year, Mario Molina and Sherwood Rowland of the University of California, Irvine, looked at what happened to them after they had been released into the atmosphere.

Because of their stability, CFCs reach the stratosphere unaltered but there they are broken up by short-wavelength ultraviolet radiation. Molina and Rowland deduced that this photodissociation would allow the release of free chlorine atoms which would then react with and ultimately destroy the ozone layer, the filter that protects the Earth from that same ultraviolet radiation. The worldwide production of CFCs at that time was almost a million tons a year, for use as refrigerants and in air-conditioning systems, as well as in spray cans, and the implications for the ozone layer were appalling.

Sharon Roan sets out to give a behind-the-scenes account of the controversy that ensued in the United States over the environmental safety, or otherwise, of CFCs. Writing very much from the viewpoint of Molina and Rowland, she vividly portrays the frustrations they faced in trying to alert the government and the chemical industry to their fears. But industrialists did not want theories, they wanted proof before they would be persuaded to take any kind of regulatory action.

The fight between industry and the atmospheric scientists was long and bitter, but in 1976 the Food and Drug Administration and the Environmental Protection Agency announced plans to phase out the use of CFCs in spray cans. The political climate was changing, however, and regulations to ban the use of non-aerosol CFCs failed to reach the statute book. In 1980, the new Reagan administration was reluctant to intervene in environmental issues — and in this case there was still a great deal of uncertainty over the extent to which CFCs were damaging the ozone layer. With science unable to resolve matters, lobbyists for industry were able to convince the legislators that any further regulations would be premature.

More evidence was needed to support Molina and Rowland's claims. In 1984 it arrived from an unexpected source. Joe Farman and his team at the British Antarctic Survey had for several years been monitoring ozone levels in the Antarctic stratosphere from their station at Halley Bay, and their data for 1977–1984 showed that a dramatic decline in ozone levels occurred in the southern spring. Farman's paper initially met with some scepticism, particularly as satellite data over the same area had not indicated any such loss of ozone. But it transpired that because the satellite instruments sometimes gave erroneous results, any readings below a certain value were flagged as 'bad' and thrown out. On reassessing the satellite data, the ozone depletion and its extent could easily be seen.

The reaction among the atmospheric science community was one of bafflement; although it had been predicted that CFCs might destroy ozone, nothing on the scale of the Antarctic 'ozone hole' had been forecast by any of the atmospheric models. The next step was to identify the cause, and in August 1986 13 scientists journeyed to the South Pole to take measurements in order to see what was going on. Uncertainties remained — there were both chemical and dynamical theories for the ozone hole — yet the following September delegates from around the world met in Montreal to sign a protocol proposing a 50 per cent cutback in the production of CFCs. A further expedition in August 1987 confirmed that CFCs were indeed the culprits and that November, after publication of the results, there were calls to strengthen the Montreal Protocol.

Since then, the Ozone Trends Panel has reported (in March 1988) that small ozone losses were occurring in the Northern Hemisphere, and in February of this year an international expedition to the Arctic announced that the chemical preconditioning necessary for ozone depletion had been found there too. NASA has just reported that this year the ozone hole over the Antarctic is as deep as that previously recorded (in 1987); it may turn out to be even deeper.

Just under half of Sharon Roan's text is devoted to events before 1984, the remainder to the discovery of the ozone hole and its ramifications — scientific, political and for industry. As a science writer on the *Orange County Register* in California, the author was well placed to cover the issues as they have developed over the past two decades. Her journalistic background betrays itself in the rather breathless prose, and the book is stronger on the politics and some of the personalities behind the ozone–CFC debate, rather than the science. But this is nonetheless a highly readable and informed account of its subject. □

Philippa Lloyd is an Assistant Editor of Nature.

Erratum

In the review of the Elsevier journal *Cell morphology* (*Nature* **341**, 362; 1989) price and frequency of publication should have been given as Dfl.298 and 4/yr, respectively. In the same issue (p.352) the price outside North America of *Chinese Journal of Biochemistry and Biophysics*, published by Allerton, should have read $280.

The correlation business

D. L. Dineley

Stratigraphy: Principles and Methods. By Robert M. Schoch. *Van Nostrand Reinhold: 1989. Pp.375. $41.95, £29.50.*

Time lapse — medial and lateral moraines of the Barnard Glacier in Alaska, formed by deposition of debris from ice-flow. This photograph was reproduced from *The Nature of the Environment, Second Edition*, by Andrew Goudie, published by Basil Blackwell.

BORING stuff, stratigraphy — that seems to be a commonly held opinion in many quarters. To judge from the programme of the Twenty-eighth International Geological Congress in Washington last July, however, it is alive, well, and indeed so robust as to command an appreciable amount of the time available. Not only has a great deal of recent stratigraphic description revealed new and surprising phenomena, but the integration of stratigraphic studies with those on tectonics, neotectonics, sedimentation and conceptual modelling is providing new interpretations of geological processes and history. The stratigraphers of course have always maintained that it would and that writing historical geology — at least the last couple of thousand million years of it — is primarily dependent upon it.

The (simple) description of the rock strata of the crust of the Earth is now a highly technical business. All concerned have been keen to see established a common means of communicating and understanding knowledge of the stratigraphic record in different parts of the world. The North American Stratigraphic Code, produced by a North American Commission on Stratigraphic Nomenclature no less, has been closely followed in other parts of the world. An International Stratigraphic Guide followed (1977). An International Commission on Stratigraphy (ICS) had been set up and was in time recognized by the International Union of Geological Sciences (IUGS). In turn it has spawned a litter of subcommissions on the stratigraphy of the different systems, working groups on boundary problems and so on. The aim is to facilitate international uniformity of practice and ease of understanding, and the ICS guide is now being revised, as has been the American (1983).

Such activities as these bodies espouse may cut across national practices, and may appear legalistic and quibbling, but in the end their influence is for the good. They have to keep in mind technological progress as well as philosophical advances — magnetostratigraphy, ecostratigraphy, chronostratigraphy — and what *they* contribute to one of the prime aims of the whole wordy business. That aim is the global correlation of rock bodies and of the events and processes they have undergone. Telling the geological time is a complementary process and product.

So much for the background, which goes to show why it is strange yet understandable that few authors have recently sought to produce a single volume that gives a global view of the principles of the discipline. Robert M. Schoch of Boston University has attempted just that task in the book under review. He has succeeded very well in what he describes as an introduction to a science in which there are often more questions than answers. To his 279 pages of text he appends a bibliography of 27 pages, plus the rather dated North American Stratigraphic Code (1983), a note on the definition and concept of geological–climate units, the timescale compiled by A.R. Palmer (1983) and the generalized lunar stratigraphy and geological timescale for the Moon.

The text is admirably concise and unambiguous. Schoch provides a general introduction to the science, describes the material basis of stratigraphy, and presents some of its conceptual foundations; the codes and conventions of stratigraphic nomenclature are dealt with, as are the different fields of physical stratigraphy, biostratigraphy and magnetostratigraphy, and the vexed topics of chronostratigraphy and 'geochronology'. (This last term is ambiguous, and the ICS is now avoiding it. The International Stratigraphic Guide uses it for the class of Period, Epoch, Age, chronozone while the Subcommission on Geochronology is concerned with radiometry leading to a geochronometic scale calibrating global chronostratigraphy.)

One may find minor points to disagree with in the book, but overall it is quite an achievement. The author is gratifyingly conversant with the history and development of his topic and this historical perspective is well treated. Keeping abreast with the developments of the past decade presents problems to every writer. Schoch, perhaps wisely, refrains from commenting on many of the most recent recommendations of the ICS and its subcommissions; for these, the reader will need to refer to the IUGS news magazine *Episodes*.

Something less than first class is the provision and choice of illustrations. They are insufficient in number, some are not very informative and others are simply not very good. Surprisingly, there is not a single graphic in the chapter on biostratigraphy and magnetostratigraphy.

For all that it is well written, this is a volume to be read in small spans. Most teachers and many researchers will find it very useful and informative, and one hopes (but rather doubts) that Earth scientists who are not primarily concerned with stratigraphic matters will browse in it. Part of the reason for that doubt is that the book is nicely produced but somehow 'low key': it is not eye-catching and in appearance is similar to a legal treatise. Stratigraphy is not boring, nor is this book — it just looks as if it is. □

Two diseases

Ann Harris and Martin Bobrow

Cystic Fibrosis. Edited by Peter Goodfellow. *Oxford University Press: 1989. Pp. 96. Pbk £15, $26.95*
The Fragile X Syndrome. Edited by Kay E. Davies. *Oxford University Press: 1989. Pp. 138. Pbk £15, $24.95*

THESE two slim, soft-covered books are the first in a new series, "Molecular Medicine", published by Oxford University Press. Each consists of five chapters by different authors, most of whom are actively engaged in research on the disease in question. In neither case do the editors appear to have imposed a uniform style, so that the individual 'mini-reviews' vary somewhat in style and quality.

Cystic fibrosis (CF) and fragile-X syndrome must be near the top of most people's list of fascinating monogenic human disorders. Cystic fibrosis is the most common serious recessive in populations of Northern European origin, with a gene frequency of about 2 per cent. The reason for this extraordinary frequency of a mutation which was, until recently, an effective genetic lethal, is unclear. Apart from this basic biological question, the disease is a considerable health problem in many countries. Electrophysiologists have gradually accumulated evidence that the basic defect lies in transmembrane ion transport. Within the past few weeks, CF has become the second major human disease locus to yield to pure 'reverse genetics', with the publication in *Science* (8 September, 1989) of the complete cDNA sequence and identification of the dominant disease-causing mutation. This achievement makes the book out of date, but renders it a useful standpoint from which to review the recent developments and those that will inevitably follow.

The first chapter is a straightforward account of the clinical features of CF, and the second deals with disease management. Against this clinical background, Chapter 3 is an excellent account of the complexities of ion transport systems and their abnormalities in CF. A basic introduction is followed by specific discussion of the sweat gland and airways' epithelia, which are known to exhibit abnormalities in CF. The fourth and fifth chapters (on molecular genetics and prenatal diagnosis) have been overtaken by events.

With a trait frequency of about 1 in 2,000 males, the fragile-X syndrome is also a formidable health-care problem and a tantalizing biological puzzle. It causes some degree of mental impairment in the great majority of male hemizygotes and a substantial minority of female heterozygotes. The clinical disorder behaves as a partially penetrant X-linked trait; the name reflects the presence of a site of preferential chromatid breakage at (or close to) the gene location of Xq27, manifest in a variable proportion of metaphase spreads from cultures treated with specific inducers or special media. Such site-specific cytogenetic manifestation of a monogenic disorder represents a unique interface between gene action, chromosome structure and clinical abnormality.

The opening chapter is again an account of the clinical aspects. It is followed by an excellent review of epidemiological studies of the disorder and its prevalence, and then a catalogue of some behavioural manifestations of fragile-X. The molecular geneticists' search for closely linked RFLPs in a condition of possible linkage heterogeneity, and with complexities in defining the phenotype, is described in Chapter 4, leaving an impression that the cloning of this particular gene may still be a little way off. A very competent review of the cytogenetics is for some reason left to the end of the book; this is a disorder that was first really defined at the cytogenetic level.

The format and pricing of these books make them accessible to a wide audience of students, and to both scientists and clinicians, each of whom is likely to learn something of the other's point of view. □

Our star

J.C. Brown

The Restless Sun. By Donat G. Wentzel. *Smithsonian Institution Press: 1989. Pp. 279. $27.95, £21.75*
The Sun: An Introduction. By Michael Stix. *Springer-Verlag: 1989. Pp. 390. DM.148, £48.50.*

As the Sun rises towards its peak magnetic activity, solar oscillation observers monotonically increase their efforts as too, it seems, do authors of solar physics books. The past few years have seen several new monographs on aspects of the subject at advanced student and introductory research level, notably those by Zirin (*Astrophysics of the Sun*), by Durrant (*The Atmosphere of the Sun*), and by Tandberg-Hanssen and Emslie (*Physics of Solar Flares*). Several others are on the way. All of these books have been valuable in meeting a long-standing need for updating recorded knowledge of various aspects of the field. But none has yet given coherent coverage of the whole subject rather than mainly the special interests of the authors.

The two volumes reviewed here are very different from one another in both level and style. Despite the generality of their titles, however, both once again fall short of providing thorough accounts of solar physics.

Wentzel's book is aimed at a general audience but is also announced as one that will be welcomed by specialists. The material is certainly easily readable and gives a clear impression of some areas of recent research. On the other hand, I found the style and presentation somewhat banal and the coverage in many areas thin and rather arbitrary. The general tone is reflected in the reference on the dust-jacket to the coronal temperature in degrees Fahrenheit. Such units are not likely to be welcomed by the general scientific reader, let alone the specialist, any more than are the trite comments to the effect that work in this field "needs only modest equipment" and "developing countries have the advantage of lower labor costs". Although such a general book cannot be expected to be comprehensive, it is disappointing to find that most areas of the subject are presented, and referenced, only in terms of very specific observations and theories, some outmoded and some speculative. On the other hand, the monochrome illustrations are too poor and the colour plates too few greatly to enhance a coffee table.

In contrast, Stix's book is aimed at advanced students. It is a careful, well-written, scholarly text, giving thorough coverage of a considerable number of selected areas, both observational and theoretical, and from physical and mathematical viewpoints. As the author himself emphasizes, the areas covered well centre on his own interests in the solar interior (oscillations, convection and magnetism), and there are sound chapters on observational tools and problems, and on the lower atmosphere. Thereafter there is a brief account of the solar chromosphere, corona, wind and flares. Unfortunately this final chapter is very restricted in both subject matter and references, giving a distorted picture of the main directions of much recent research in these topics. Nevertheless, within its limits *The Sun* is a solid piece of work.

At the advanced level, solar physics is most comprehensively covered by *The Sun as a Star*, edited by S. Jordan, and the three-volume set *Physics of the Sun*, edited by P.A. Sturrock. But these collections of articles are dating fast, and there remains a gap in the literature for a scholarly monograph covering all of the field. □

POWER FROM THE WIND

This new 26 minute video from the Central Electricity Generating Board examines the centuries old challenge of harnessing the power of the wind. Presented by David Bellamy and shot on location in Barbados, Holland, the Orkneys and mainland Britain, it considers the historical use of the wind's energy and the current revival of interest in wind power to produce electricity. David Bellamy looks at the development of 'wind-turbines' and at the part that they can play in electricity production, both in small island communities and in complex industrial societies. He also considers plans in Britain to construct three 'wind farms', and the environmental impact of wind power technology.

The most accurate and up-to-date guide to the status and development of human therapeutic proteins . . .

Genetically Engineered Human Therapeutic Drugs

D. Copsey and S.Y.J. Delnatte, *Pantech Partners*

Genetically Engineered Human Therapeutic Drugs is a comprehensive reference source that provides up-to-date information on human therapeutic proteins in a convenient, logically organized format. Based on evidence from clinical studies reported in the academic, clinical and biological research journals, the information provided in this work is among the most accurate and objective information available.

PART I: Clinical Drug Development

Part I consists of reviews of 77 proteins under 18 therapeutic categories. These reviews examine the clinical research being undertaken in the major unsatisfied therapeutic areas. Where available, each review provides information on: Therapeutic Indications • Clinical Research Background • Clinical Studies.

PART II: Commerical Drug Development

Part II examines 90 proteins under 25 therapeutic categories currently being developed for their commercial potential as therapeutic drugs. It is organized alphabetically by generic rDNA protein. Following the introductory section for each protein, are tables organized by stage of development: Launched Products • Registered / Approved Products (Not yet launched) • Products in Clinical Trials • Products in Research or Pre-Clinical Development • Products under Clinical Agreements

NEW FROM OXFORD

NEW EDITION

Gel Electrophoresis of Proteins: A Practical Approach

Second Edition

Edited by **B. D. Hames and D. Rickwood**

Contents: One dimensional polyacrylamide gel electrophoresis; Isoelectric focusing; Two-dimensional gel electrophoresis; Immunoelectrophoresis; Peptide mapping; Appendices.

0 19 963074 7, 250 pp., illus., spiral bound, IRL Press, January 1990 £27.00
0 19 963075 5, paperback £18.00

Solid Phase Peptide Synthesis: A Practical Approach

E. Atherton and R. C. Sheppard

Contents: Peptide synthesis—An introduction; Solid phase peptide synthesis—The Merrifield technique; Fmoc-polyamide solid phase peptide synthesis—General principles; The solid support; Fluorenylmethoxycarbonyl amino-acids; Linkage agents; Activation procedures; Instrumentation for Fmoc-polyamide solid phase synthesis; Analytical and monitoring techniques; Reaction procedures and operating techniques; Resin cleavage and purification techniques; Illustrative synthesis.

0 19 963066 6, 250 pp., illus., spiral bound, IRL Press, October 1989 £27.00
0 19 963067 4, paperback £18.00

Fermentation: A Practical Approach

Edited by **B. M. McNeil and L. M. Harvey**

Contents: Setting up equipment for laboratory fermentation; Laboratory fermentation; Innoculum preparation and fermenters; Fermentation modelling; Fed batch and continuous culture; Electrodes for fermentation; Instrumentation and control; Sterilisation; Animals cell culture.

0 19 963044 5, 276 pp., illus., spiral bound, IRL Press, November 1989 £29.00
0 19 963045 3, paperback £19.00

Proceedings of the Sixteenth Symposium on Nucleic Acids Chemistry

Edited by **Hiroshi Takaku**

Contents: Thirty-nine papers were presented by distinguished Japanese scientists, abstracts of which are presented in this volume. The subjects covered include the identification of the mutation responsible for the beta-thalassemia, the DNA marker linked to congenital malformations, and effects on DNA of antitumour antibiotics.

Nucleic Acids Symposium Series No. 21
0 19 963127 1, 150 pp., illus., paperback, IRL Press, October 1989 £30.00

Medical Mycology: A Practical Approach

Edited by **E. G. V. Evans and M. D. Richardson**

Contents: General guidelines on laboratory diagnosis and antifungal monitoring; Direct microscopy; Culture and isolation of fungi; Identification of the agents of superficial mycoses; Identification of yeasts; Identification of the agents of subcutaneous mycoses; Identification of the agents of systemic mycoses; Identification of common culture contaminants; The maintenance and preservation of fungi; Serological tests; Methods of antifungal drugs; Histopathology.

0 19 963010 0, 318 pp., illus., spiral bound, IRL Press, 1989 £37.50
0 19 963011 9, paperback £25.00

NEW EDITION

Gel Electrophoresis of Nucleic Acids: A Practical Approach

Second Edition

Edited by **D. Rickwood and B. D. Hames**

Contents: Gel electrophoresis of RNA; Gel electrophoresis of DNA; Pulsed field electrophoresis of DNA; two dimensional gel electrophoresis of nucleic acids; gel retardation analysis of proteins binding to DNA and RNA; Nucleic acid footprinting; Electrophoresis of nucleoproteins; Appendices.

0 19 963082 8, 272 pp., illus., spiral bound, IRL Press, February 1990 £27.00
0 19 963083 6, paperback £18.00

Electrophoretic Studies on Agricultural Pests

Hugh D. Loxdale and J. Den Hollander

Includes: Electrophoresis in agricultural pest research—A technique of evolutionary biology; Electrophoretic studies: Perspectives for population biology; Genetic studies of species differences and their relevance to the problem of species formation in *Drosophila*; the complexities of host races and some suggestion for their identification by enzyme electrophoresis; Population genetics studies of fruit flies of economic importance, especially medfly and olive fruit fly, using electrophoretic methods; Host-associated differentiation in armyworms (Lepidoptera: Noctuidae): an allozymic and mitochondrial DNA perspective; Other topics.

Systematics Association Special Volumes No. 39
0 19 857710 9, 400 pp., illus., Clarendon Press, December 1989 £65.00

Nucleic Acids Sequencing: A Practical Approach

Edited by **C. J. Howe and E. S. Ward**

Contents: Contributors; Abbreviations; Introduction; The use of single-stranded DNA phage in DNA sequencing; Sequencing single-stranded DNA using the chain-termination; Troubleshooting in chain-termination DNA sequencing; Sequencing of double-stranded DNA; Maxam and Gilbert sequencing using one metre gel systems; RNA sequencing; Computing; Automated DNA sequencing.

0 19 963056 9, 250 pp., illus., spiral bound, IRL Press, November 1989 £29.00
0 19 963057 7, paperback £19.00

Liposomes: A Practical Approach

R. R. C. New

Contents: Introduction; Preparation of liposomes; Liposome characterization; Covalent attachment of proteins to liposomes; Physical methods of study; Liposomes in biological systems; Appendices: I. Miscellaneous methods; II. Manufacturers and suppliers; III. Standard texts of liposomes and phospholipid membranes.

0 19 963076 3, 272 pp., illus., spiral bound, IRL Press, January 1990 £27.00
0 19 963077 1, paperback £18.00

The NMDA Receptor

Edited by **G. L. Collingridge and J. C. Watkins**

Contents: The NMDA receptor concept: origins and development; Agonists and competitive NMDA antagonists; Non-competitive antagonists of N-methyl-D-aspartate; Regional variation in NMDA receptor properties; *In vitro* preparations of spinal cord or brain which can be used for grease gap electrical recording of excitatory amino acid action; NMDA receptors in synaptic pathways; The role of NMDA receptors in synaptic integration and the organization of complex neural patterns; The NMDA receptor, its channel, and its modulation by glycine; NMDA receptors and long-term potentiation in the hippocampus; NMDA receptors and developmental plasticity in visual neocortex; Other topics.

0 19 963125 5, 200 pp., illus., paperback, IRL Press, December 1989 £25.00

Medical Bacteriology: A Practical Approach

Edited by **P. M. Hawkey and D. A. Lewis**

Contents: Bacteriology of urine; Sterile body fluids; Respiratory tract; Tissue infections; Intestinal disease; Susceptibility testing; Antibiotic assays; Record-keeping; Quality control; Nosocomial infection; Epidemiological techniques for the investigation of bacterial infections.

0 19 963008 9, 344 p., illus., spiral bound, IRL Press, October 1989 £38.00
0 19 963009 7, paperback £25.00

Brief history of the Phobos mission

R. Z. Sagdeev & A. V. Zakharov

The spacecraft Phobos 1 and 2 were launched on 7 and 12 July 1988. The mission was to have three stages: investigations of the Sun and interplanetary space during the flight from Earth to Mars; studies of both Mars and Phobos during the orbit of the spacecraft around Mars; and studies of Phobos as the spacecraft approached to within 50 m of its surface. Contact with Phobos 1 was lost on 1 September 1988 and contact was also lost with Phobos 2 just before the third stage of the mission. This article introduces fourteen papers which cover the results of the second stage of the mission.

NO spacecraft were sent to Mars for 13 years after the Viking 1 mission. This 'moratorium' was broken in 1988 by the launch of two Soviet spacecraft, Phobos 1 and Phobos 2. The main destination of the mission was not Mars, but Phobos, one of its two moons. This reflected the growing interest in the minor bodies of the Solar System. After the success of the Vega, Giotto and Suisei missions to comet Halley, it was natural to 'try' an asteroid or a little moon. From this point of view, Phobos was an ideal choice, as in its spectral characteristics, it resembles a real asteroid, but is much easier to approach, using the martian gravitational field to manoeuvre.

Initial information about the martian moons was based on results from the Mariner 9 and the Viking missions. The minimum distance at which Viking 1 approached Phobos was ~100 km. The Phobos spacecraft was to have come as close as ~50 m to Phobos which would have made it possible to obtain high-spectral-resolution television images of the surface of Phobos, to study the elemental and mineralogical composition of the regolith, the internal structure of Phobos, and to put landers on the moon's surface.

It is safe to say, however, that Mars itself was not exhausted as an object of exploration. Moreover, Mars will hopefully play a central part in the long-term Soviet programme of Solar System exploration.

Besides studies of Phobos, and the martian surface, atmosphere and plasma environment of Mars, both of the Phobos spacecraft were to make observations of the Sun and interplanetary space during the flight from Earth to Mars[1].

A large international team took part in the preparation of the Phobos project. The onboard scientific payload was prepared by scientific teams from Austria, Bulgaria, Hungary, East and West Germany, Ireland, Poland, Soviet Union, Finland, France, Switzerland, Sweden, Czechoslovakia and the European Space Agency (ESA). The US Deep Space Network participated in the ballistic support of mission operation.

Spacecraft and scientific payload

Phobos (Figs 1 and 2) is a next-generation spacecraft after those of the Venera-type, last used in the Vega mission (1984–86). The Phobos spacecraft, developed in the Babakin Centre, was planned as a base spacecraft for the next generation of interplanetary missions[2]. It took eight years to complete the technical and scientific preparation of Phobos, and the schedule, which was altered drastically several times, was to be as follows: (1) The spacecraft would reach the vicinity of Mars and be put in an elliptical orbit; (2) several successive corrections would bring the orbit closer to that of Phobos. During this period Mars and Phobos would be studied by remote methods, the latter up to ~100 km; (3) in the culmination, the spacecraft would approach the surface of Phobos, to an altitude of 30–50 m for a short time, release two small landers and perform two 'active' probing experiments. One of the latter involved the use of laser beams to evaporate small samples of material and analysis of the samples by sensitive mass spectrometers. Unfortunately this, the most novel part of the programme was not realized.

The Phobos mission involved the launch of two spacecraft, Phobos 1 and Phobos 2. The total pre-launch weight of each spacecraft was 6,200 kg, of which 3,600 kg was the weight of the propulsion system, which was to be separated from the spacecraft after the most power-consuming man- oeuvres of the spacecraft were performed in setting up the reference orbit.

The contents of the scientific payload aboard Phobos 1 differed slightly from that of Phobos 2. The total weight of scientific payload aboard each was ~500 kg (with structural elements and cables). In accordance with the scientific aims of the mission, the instrumentation may be classified as planetary, plasma and solar. Table 1 presents the scientific instruments of the orbiter which provided the 'planetary' data of the mission, that is, data from the exploration of Phobos, the martian surface and atmosphere. All these instruments were mounted within the spacecraft so that their sensitive elements were oriented in

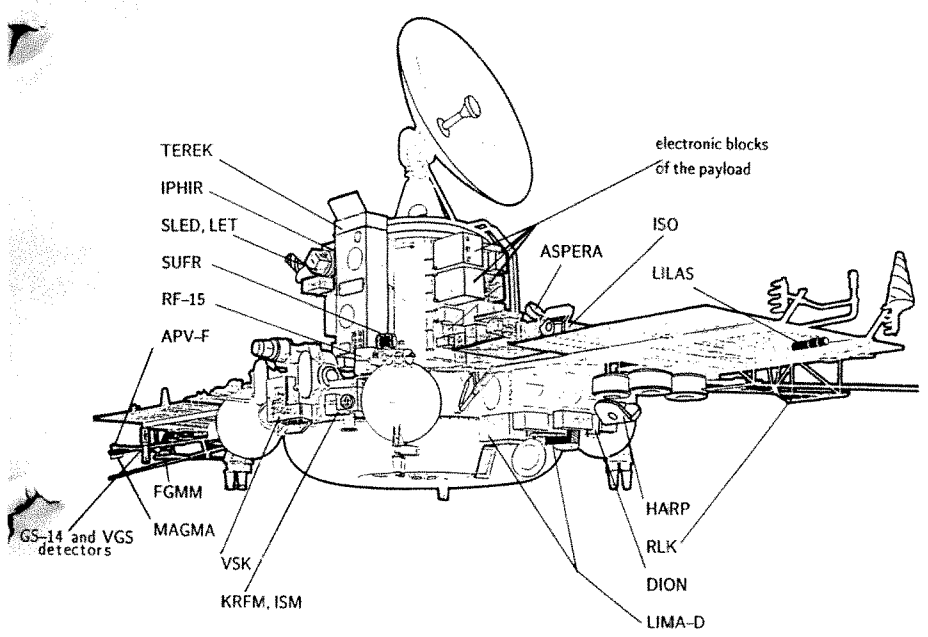

FIG. 1 Arrangement of scientific instruments aboard Phobos 2.

an anti-sunward direction (with the exception of ISO). The spacecraft was to change its orientation to point the instruments towards Phobos or Mars while on the martian orbit. One of the Phobos landers was capable of remaining at the surface for a long time and contained instruments for celestial mechanics experiments, analysis of regolith and for television imaging of landing places. The other lander, called a 'hopper', could jump over the surface to study the composition of the Phobos soil in several places.

The 'plasma' part of the programme concentrated on the exploration of the magnetic field and plasma environment of Mars, measurements of the parameters of the interplanetary medium, the Sun and cosmic rays. A list and the main characteristics of the instruments are given in Table 2. Table 3 presents the solar-package instrumentation and γ-burst experiments.

The project and the scientific programme

The Phobos 1 and Phobos 2 spacecraft were launched on 7 and 12 July 1988, respectively, by Proton rockets from the Baikonur cosmodrome. On 16 and 21 July the first correction of the trajectory was made. On 1 September, Phobos 1 did not establish radio contact during the planned session with Earth and did not answer multiple radio requests. The analysis of up-link commands sent during the previous communication session, that is on 28 August, showed that an erroneous command had been given which switched off the thrusters of the attitude control system. Phobos 1 changed its orientation and solar panels were turned away from the Sun. When this mistake was discovered, on 1 September, the power supply available on board was not enough to react to powerful radio signals from the Earth. Thereafter the mission had only Phobos 2 to carry out the scientific programme.

On 29 January 1989, a retarding impulse was applied ($\Delta v = 815.1\ \mathrm{m\,s^{-1}}$) and Phobos 2 was transferred from the Earth-to-

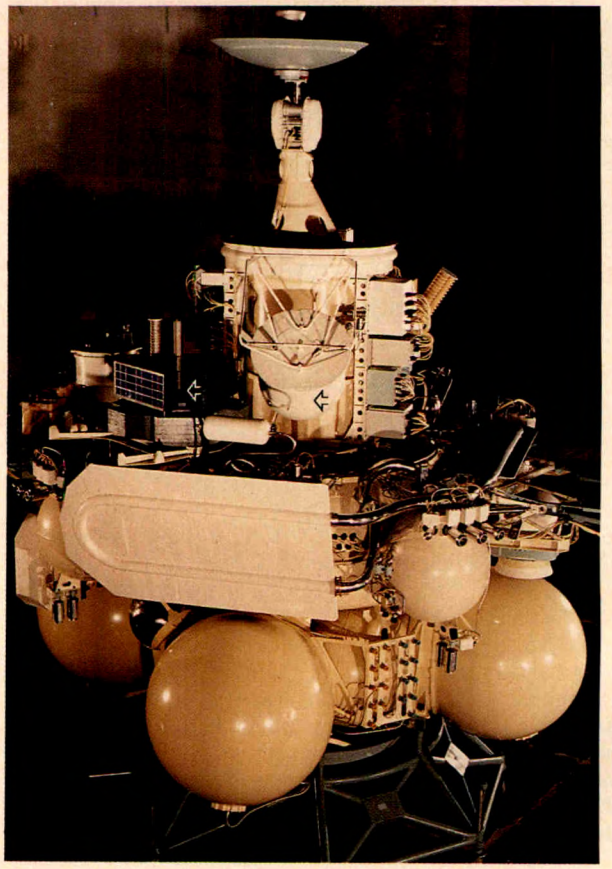

FIG. 2 Phobos 2: white arrow, long-term autonomous lander; black arrow, 'Hopper'.

Mars trajectory to the elliptical equatorial orbit of a martian artificial satellite. Table 4 summarizes the parameters of the elliptical orbits. On 12 February, after four turns around Mars, the orbit was corrected ($\Delta v = 114.6$ m s^{-1}) so that its pericentre came closer to the orbit of Phobos. On 18 February one more retarding impulse was applied ($\Delta v = 722$ m s^{-1}) and the spacecraft's orbit became circular, almost the same as that of Phobos although somewhat higher. Table 4 lists the parameters of this circular orbit. This manoeuvre completed the circular-orbit formation, and the self-contained propulsion system was jettisoned. The spacecraft's motion was then controlled by low-thrust engines.

After two intermediate corrections of the circular orbit were made on 7 and 15 March ($\Delta v = 37.6$ m s^{-1} and 1.0 m s^{-1}, respectively) the spacecraft was transferred to a quasi-synchronous orbit ($\Delta v = 39.7$ m s^{-1}) on 21 March (orbiting around Mars practically in synchrony with Phobos). For the coordinate system fixed with the three-axis-stabilized spacecraft, this led to Phobos spinning at the anti-solar side of the spacecraft at a distance of 200–600 km. The next stage involved transferring Phobos 2 to an orbit closer to Phobos and then its controlled departure from this orbit to approach the satellite. Figure 3 presents schematically the Phobos 2 orbits around Mars. The Phobos surface image (see Fig. 4) taken by the Phobos 2 television system has marked sites for landers, as well as the region over which the spacecraft should drift at the closest approach.

On 27 March 1989, after television imaging of Phobos during which Phobos 2 changed its orientation so that its field of view (FOV) pointed at Phobos, we lost radio contact with the spacecraft. Four hours later, after unsuccessful attempts to set up radio contact, a weak signal was received with the last message from Phobos 2: the spacecraft was spinning in the off-design mode, extremely adverse in terms of power supply for the spacecraft systems, and was unable to support reliable radio communication with Earth. Further attempts to communicate with Phobos 2 were ineffective. Although this time, controller error was not the cause, the spacecraft loss was again due to failure in orientation control, which quickly led to energy exhaustion.

We are still awaiting the final verdict as to how Phobos 2 was lost, but several suggestions have been made. One is that orientation could be lost because of on-board computer malfunction. The contractor (Babakin Center) raised the question of possible impact between the spacecraft and large dust particles, the concentration of which should be, in principle, at a maximum around the orbit of Phobos because of regolith secondary particles knocked out by micrometeorite and meteorite impacts.

Because this problem might be of particular interest for future missions we consider a simple model of a dust torus on orbits near Phobos. For estimation purposes it is reasonable to proceed by analogy with the regolith particle knocking-out rate on the moon. However, the majority of secondary particles knocked out from the lunar surface return with free-fall time because of gravity. For Phobos, which has insignificant gravity (with the escape velocity slightly over $v = 10$ m s^{-1}), we consider, for simplicity, that all the material knocked out from the surface goes into orbit around Mars. The resurface rate is assumed, by the order of magnitude, to be close to that on the Moon (10^{-7} cm yr^{-1}). Sooner or later these particles, depending on the characteristics of their orbits, should come into contact with Phobos. So, at the equilibrium of Phobos with the dust torus, the amount of secondary particles deposited on the surface

should, on average, be the same as those that left it. Without going into details of stochastic diffusion of these particle orbits (according to calculations made by Dr G. M. Zaslavsky's team), which ensures mixing for 1 yr, it is easy to evaluate the probability of a spacecraft's impact with dust particles occurring within the dust torus. To find the upper limit, we suppose that the secondary mass of knocked-out regolith is converted to 10 g mass 'bullets' (this mass was conditionally considered as a danger for the spacecraft). With the regolith density 2 g cm^{-3}, the surface of Phobos loses (and hence, takes back) $\sim 10^5$ g of particles per year. The spacecraft, with an effective area of $\sim 30\ m^2$, will, on average, collide once every 300 yr. It should again be mentioned that the probability of the spacecraft colliding with a particle of mass ~10 g is, in fact, many orders lower.

The similar conclusion that the probability of spacecraft impact with a dangerous particle is extremely low, was made by the Viking team (B. Murray, personal communication).

Conclusion

The failure of the Phobos spacecraft before completion of the mission invites a discussion on the interaction of scientists with industry (customers with constructors) to ensure reliability and survival of a mission. Glavkosmos in the Soviet Union (the prime contractor) has promised to change its approach to future missions (would this be real '*perestroika*'?). The scientific and engineering team must discuss technical problems in the early stages of project preparation.

The results of measurements made during the flight from Earth to Mars (52 days for Phobos 1 and 200 days for Phobos 2) as well as in orbits around Mars (57 days for Phobos 2) have their own significance; results from the second stage of the mission will be discussed in the papers which follow. □

Note added in proof: Since the paper was submitted, it has been verified that Phobos 2 was lost because of an on-board computer malfunction.

In February and March 1989 the Phobos 2 spacecraft took 37 television images of the moon Phobos from a distance of 190–1,100 km. These images complement the data from the Mariner 9 and Viking missions by providing higher-resolution coverage of a large region west of the crater Stickney (70–160° W) and by providing disk-resolved measurements of surface brightness at a greater range of phase angles and wavelengths. The data are being used to update the three-dimensional model of Phobos, to provide improved determinations of its density and orbital dynamics and to study its surface colour, composition and texture. Here we present preliminary findings, which include different integrated photometric behaviour in visible and near-infrared bands, observation of a region immediately west of Stickney which is relatively free of large grooves, the prevalence of bright rims on grooves and younger craters and low bulk density.

The videospectrometric system (VSK) Fregat was developed cooperatively by Bulgaria, East Germany and the Soviet Union. VSK combines a three-channel television (TV) camera, a spectrometer, and a memory with a capacity >1.5 Gbit. The TV camera had two short-focal-length ($f = 18.5$ mm) channels and one longer-focal-length ($f = 100$ mm) channel with angular resolutions of 3.3×4.5 arcmin and 0.62×0.83 arcmin, respectively. The spectral sensitivities of the three TV channels are shown in Fig. 1. The TV camera and spectrometer had charge-coupled device (CCD) detectors with photosensitive sections and memory sections of 288×505 pixels, and used an 'electronic shutter' technique.

Because of the premature loss of the Phobos 2 spacecraft, the TV observations of Phobos were limited to 37 images of Phobos and Phobos against Mars, including 13 higher-resolution images in channel 2 which cover most of the surface of Phobos except for that obscured by Mars. Over two-thirds of Phobos had been viewed by Viking at a spatial resolution of 50 m pixel^{-1} or better. However, the area to the west of Stickney (70–160° W) had previously been viewed at a very oblique angle and at a spatial resolution of a few hundred metres per pixel. VSK imaged this area at low emergence angles and at a spatial resolution of 40–80 m pixel^{-1} (Fig. 2*b*, *d*, *e*). Because of the generally low phase angles the topography of this area is still not seen very clearly, but craters and grooves can be recognized. Comparison with Viking-based maps[1,2] shows that several new grooves can be identified in the area 130–180° W (Fig. 2*e*); imaging under the same conditions failed to reveal new grooves closer to Stickney (Fig. 2*d*), an area already known from Viking images to be relatively free of larger grooves. Either large grooves did not form here or they were buried by ejecta from Stickney.

The control network of Phobos derived from Viking data[3] was found to be generally consistent with VSK images. However, deviations of up to 0.5–1 km were observed when limb profiles of Phobos were compared with those derived from the Phobos topographic map[4].

In images taken at phase angles of 7–8° (Fig. 2*d*, *e*), many craters and grooves are observed to have on their rims and walls, material that is 20–30% brighter than average for Phobos surface materials. At moderate phase angles (Fig. 3*b*, *c*, *f*) the difference in brightness disappears, implying that this material has a higher normal albedo as well as a higher phase coefficient at small phase angles. This effect had also been observed on Viking images[1,5,6] and had been interpreted as resulting from variations in surface texture.

Alternatively, on dark bodies like Phobos both a higher normal albedo and a higher phase coefficient can be explained by the diffraction mechanism of opposition surge[7], as a higher particle single-scattering albedo possibly resulting from less regolith darkening and maturation (the common shadow mechanism implies decrease of the phase coefficient with increase of single-scattering albedo). The lesser maturity of regolith on the crater

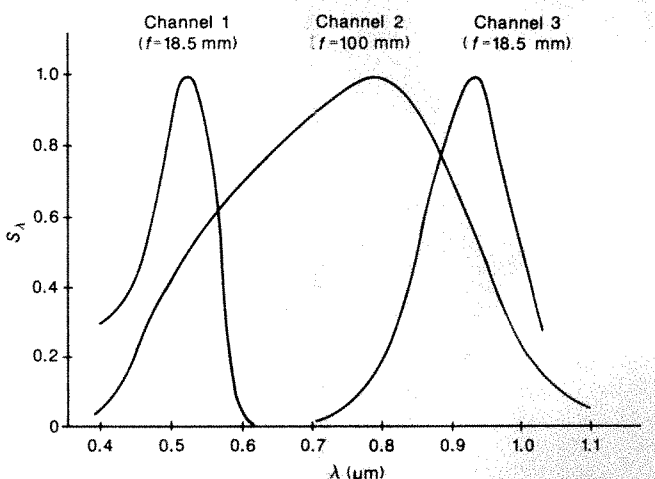

FIG. 1 Spectral sensitivities of the VSK TV channels. S_λ, relative spectral sensitivity; λ, wavelength (μm); *f*, focal length.

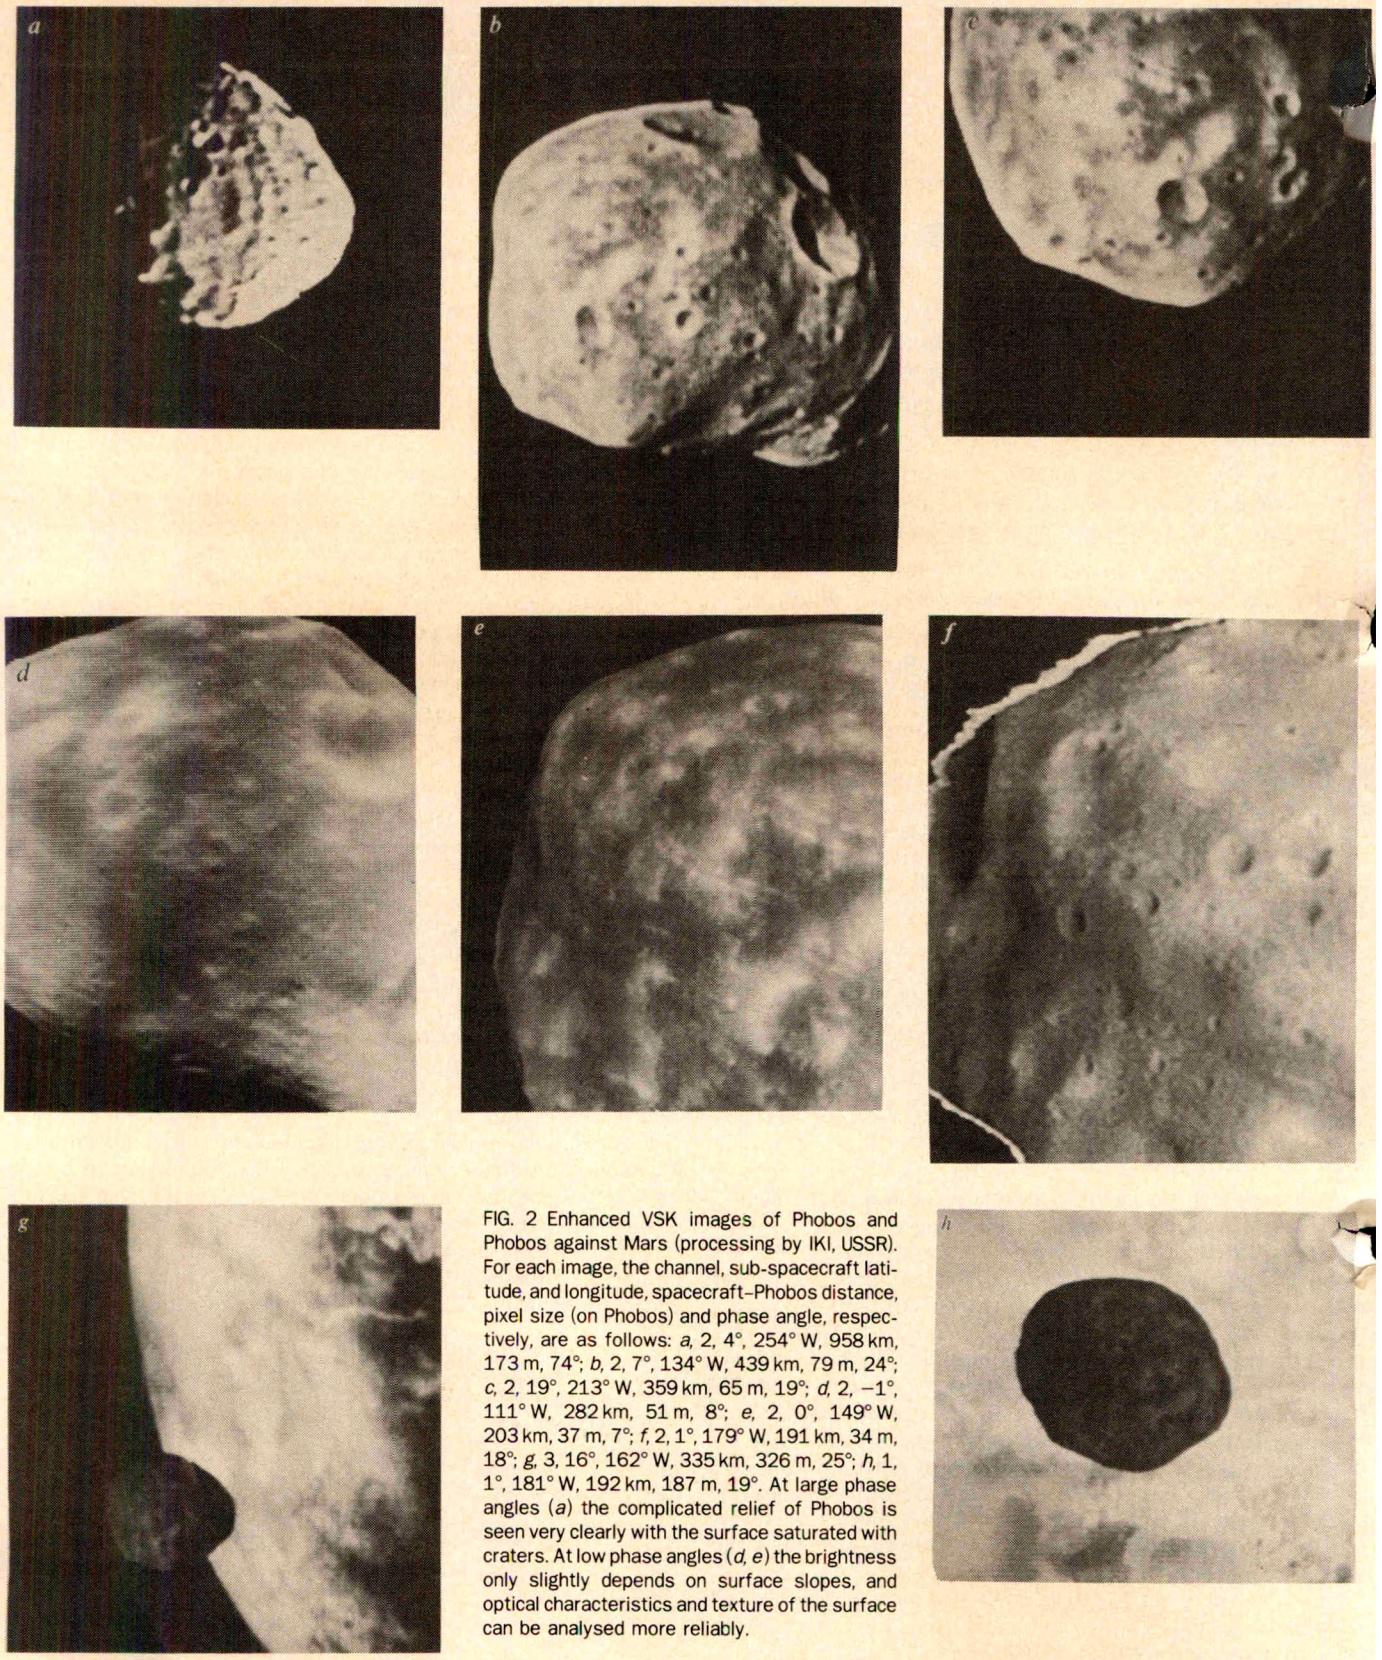

FIG. 2 Enhanced VSK images of Phobos and Phobos against Mars (processing by IKI, USSR). For each image, the channel, sub-spacecraft latitude, and longitude, spacecraft–Phobos distance, pixel size (on Phobos) and phase angle, respectively, are as follows: *a*, 2, 4°, 254° W, 958 km, 173 m, 74°; *b*, 2, 7°, 134° W, 439 km, 79 m, 24°; *c*, 2, 19°, 213° W, 359 km, 65 m, 19°; *d*, 2, −1°, 111° W, 282 km, 51 m, 8°; *e*, 2, 0°, 149° W, 203 km, 37 m, 7°; *f*, 2, 1°, 179° W, 191 km, 34 m, 18°; *g*, 3, 16°, 162° W, 335 km, 326 m, 25°; *h*, 1, 1°, 181° W, 192 km, 187 m, 19°. At large phase angles (*a*) the complicated relief of Phobos is seen very clearly with the surface saturated with craters. At low phase angles (*d*, *e*) the brightness only slightly depends on surface slopes, and optical characteristics and texture of the surface can be analysed more reliably.

and groove rims may be a result of their younger age or of sliding of surface regolith off steeper slopes, perhaps driven, under the low gravity of Phobos, by impact-generated seismic vibrations or by diurnal surface-temperature variations.

To test these hypotheses, the relationship of photometric properties of crater rims and walls with the degradation state of the crater was investigated. This was done by mapping and classifying craters of diameter >1 km within the area observed at low phase angles in the combined Viking and Phobos 2 data sets, extending from ~50–70° N to 50° S and from 40° to 300° W. Each crater was classified into one of four morphological groups previously defined in ref. 3, although assignments of individual craters to different groups were revised on the basis of the new VSK images for the area 70–160° W. In addition, each crater

TABLE 1 Extent of bright material in different crater classes

Crater group	Number of craters	Extent of bright material: More than half the rim (%)	Less than half the rim (%)	Absent (%)
Fresh	3	100	—	—
Partly degraded	28	57	15	28
Degraded	8	12	38	50
'Ghost' craters	6	—	33	67

was classified as one of three types based on the presence and the continuity of bright material along the rim. The results, summarized in Table 1, clearly show that bright rims and walls are prevalent on fresher craters and disappear as the craters are degraded, consistent with the occurrence of bright rims on younger craters with less mature regolith.

Higher brightness at low phase angles is also shown by rim materials of grooves, although generally not by groove floors. Several mechanisms by which grooves could be formed have been proposed, and testable predictions have been made about the physical properties of grooves[8]. The models are: (1) the 'fracture and drainage' model[2] which proposes exposure of fresher material by sliding of regolith from groove walls and floors; (2) the 'fracture and degassing' model[1,2], which proposes an accumulation on groove rims of material from depth that may have a composition or texture different from that of surface material; and (3) the 'ejecta re-impact' models[9,10], whereby groove-floor material is compressed and material, possibly with a different composition or texture, is excavated from shallow depths. If the higher normal albedo of the rim material indicates a compositional or textural difference from intergroove materials, then this is more consistent with the 'fracture and degassing' and 'ejecta re-impact' models of groove origin. The 'fracture and drainage' model can explain the higher normal albedo of groove rims only by the lesser maturation of the regolith.

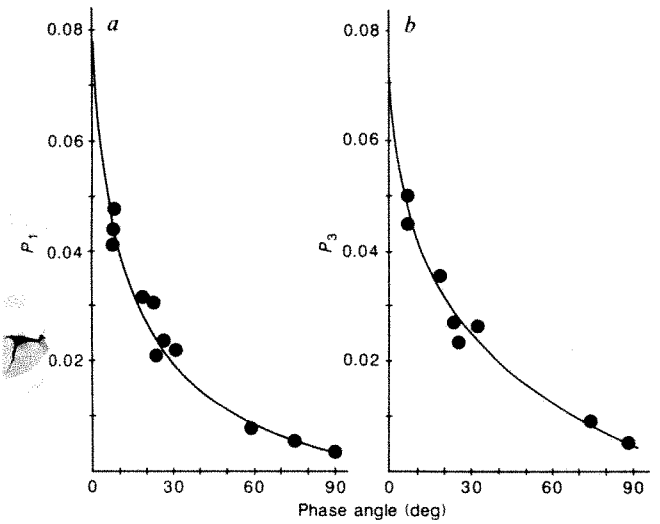

FIG. 3 The disk-integrated reflectance (P) of Phobos against phase angle at visible (channel 1, *a*) and near infrared (channel 3, *b*) wavelengths. The ground-based calibrations of the VSK absolute sensitivity were used, and the correction of CCD sensitivity for temperature was applied. The error of relative brightness measurements is 5% in both channels, and the uncertainty of absolute calibration is 10% in channel 1 and 15% in channel 3. Changes in the visible area of Phobos were accounted for by assuming that Phobos is a triaxial ellipsoid $26.6 \times 22.2 \times 18.6$ km[16]. The experimental points were fitted to the model phase function[14], with the geometrical albedo p and the slope parameter Γ being free parameters. Their best fitting values are: $p = 0.080 \pm 0.010$, $\Gamma = 0.046 \pm 0.035$ (visible) and $p = 0.071 \pm 0.013$, $\Gamma = 0.252 \pm 0.085$ (near infrared). Error bars for geometrical albedo include both statistical and absolute calibration errors. Earlier values of $p = 0.07 \pm 0.01$ and $\Gamma = 0.044$ had been found for Phobos at visible wavelengths[14]. Visible and near-infrared images were taken shortly after one another, with subspacecraft latitude being constant to within 0.01° and subspacecraft longitude changing by less than 2°. The scatter of points is correlated in both channels and may be partly accounted for by deviations of Phobos's figure from an ellipse.

The VSK data obtained in the range of phase angles 7–90° supplement the ground-based[11] and spacecraft[12,13] measurements of the disk-integrated reflectance of Phobos at visible wavelengths and allows comparison of these measurements with near-infrared data (Fig. 3). At visible wavelengths the new data agree excellently with the previously determined phase function[13,14], which approximates all previous ground-based and spacecraft measurements. The geometrical albedo of 0.080 ± 0.010 is slightly larger, but is consistent, to within the stated accuracy, with the previous value of 0.07 ± 0.01. At near-infrared wavelengths the geometrical albedo of 0.072 ± 0.013 does not differ significantly from the geometrical albedo at visible wavelengths, but the phase function curve is found to be shallower (the slope parameter is distinctly different at least at the 1σ level). Either the surface of Phobos exhibits different photometric behaviours at different wavelengths or, as continuing research suggests, this effect may result from areas imaged at higher phase angles being slightly redder in colour than areas seen at low phase angles.

An important auxiliary task of the TV imaging of Phobos was to update the orbital elements of Phobos to aid the spacecraft manoeuvres on the approach to Phobos. The error in predicting the location of Phobos was decreased by an order of magnitude to several kilometres. The navigation tracking of the spacecraft resulted in a more accurate estimation of the Phobos mass, that is $1.08 \pm 0.01 \times 10^{19}$ g[15]. Taking from model calculations, the volume of Phobos to be $5{,}530 \pm 300$ km^3 (ref. 16), a mean density of 1.95 ± 0.1 g cm^{-3} is then obtained, lower than the value of 2.2 ± 0.2 g cm^{-3} based on Viking data[17]. This value is significantly less than the densities of materials having spectral reflectances similar to that of Phobos[18] (for example, hydrous and anhydrous carbonaceous chondrites and optically blackened mafic material[19–21]) strongly suggesting that the interior of Phobos could be more or less porous or contain ice.

Further analysis of the VSK data is now in progress, with emphasis on (1) updating the three-dimensional model of Phobos and topographic and geological maps of its surface; (2) characterizing spectral reflectance and photometric properties of the surface of Phobos, and identifying the implications of these results for surface composition and texture, and mechanisms of formation and evolution of craters and grooves; and (3) improving determination of the shape, volume and forced libration amplitude of Phobos, and searching for the offset of the centre-of-mass from the geometrical centre to place additional constraints on internal structure and mass distribution. □

IMPORTANT information about the properties of the outermost layer of regolith on Phobos can be obtained from infrared thermal radiometry and spectrophotometry of the reflected radiation. From the analysis of Mariner 9[1,2], Viking 1,2[2–4] and ground-based experimental data it was concluded that the surface layer of Phobos consists of fine-grained material (regolith)[1] with a composition close to that of carbonaceous chondrites[2,3]. In the course of these measurements, Phobos was observed as a point-like object. Here we present results obtained with a resolution 1/20–1/40 of the mean Phobos diameter showing, for the first time, inhomogeneities in the thermal and spectral properties of the surface of Phobos.

The combined multichannel instrument KRFM on board the Phobos 2 spacecraft consisted of a radiometer with an angular resolution of 30′, capable of measuring thermal emission in the range 6–50 μm, and a photometer having an angular resolution of 15′, detecting in nine bands in the spectral range 320–600 nm. Radiometer channels 1–6 covered the ranges 4.8–6.4, 6.1–7.8, 7.2–9.3, 9.2–13.6, 14.3–15.9 and 16.5–49 μm, respectively, and spectrophotometer channels 1–9 measured radiation of wavelengths of 320, 328, 346, 363, 410, 445, 488, 550 and 600 nm. The spectral response of the photometer channels were gaussian, and the optical axes of the radiometer and the photometer were coincident.

The orbiting instrument was used to study Mars for two months; those results will be published elsewhere. On 25 March 1989, one of the last days on which Phobos 2 functioned, we obtained observations of Phobos from a height of 190 km. When the instrument was switched on, Phobos was already in the field of view. The relative spacecraft speed was 43 m s^{-1} and for

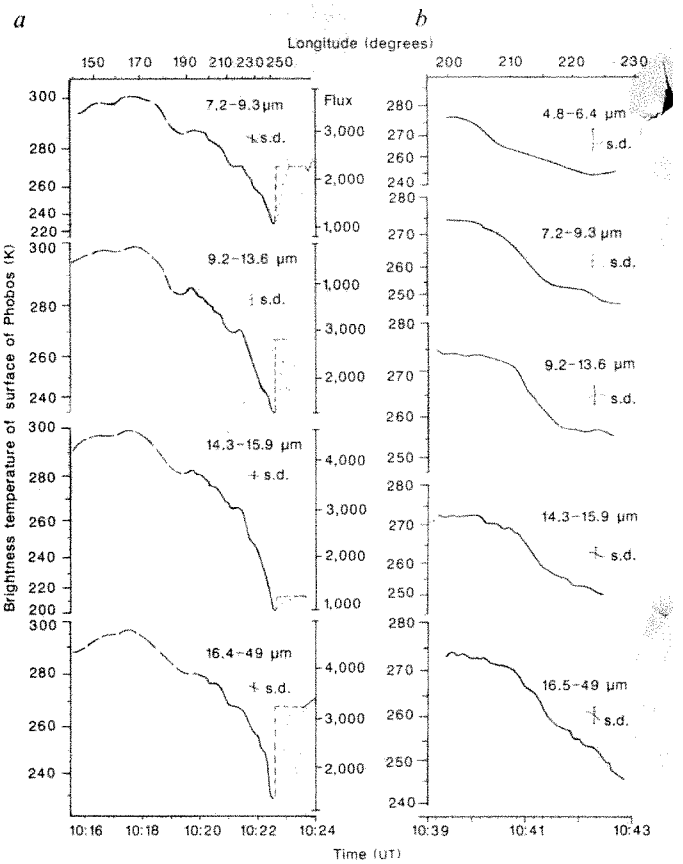

FIG. 2 The profiles of brightness temperature for *a*, track I (latitude −4.5°), radiometer channels 3–6 from top to bottom and *b*, track II (latitude −2.7°), radiometer channels 1 and 3–6 from top to bottom. Standard deviations are shown for each profile. Flux is given in arbitrary telemetry units.

~420 s the track covered a band on Phobos at a latitude of about −4.5°, from 140° longitude to the limb which was at 260° longitude (west). The surface resolution was 1.9 km and 1 km for the radiometer and photometer, respectively. After this set of observations the spacecraft turned back and measurements were obtained along a second track at −2.7° latitude, 196–229° longitude (not reaching the limb). Figure 1 shows the track positions on the surface of Phobos. The tracks crossed a number of depressions (180°–195°, 200°–210° and 215°–240°).

The profiles of brightness temperature T_B for both tracks are shown in Fig. 2. The optical axes of the radiometer channels did not strictly coincide as can be seen by comparing the profiles for 7.2–9.3 and 14.3–15.9 μm and for 9.2–13.6 and 16.5–49 μm (Fig. 2). This offset results in a difference of about half of a field of view (~1 km at the surface).

Determining surface local geometry, solar and spacecraft zenith angles, local solar time and the coordinates of the observed point, is a rather complicated problem for Phobos. The non-regular shape of Phobos cannot be described by a simple mathematical model. The normal to the model surface can be significantly different from that to the physical surface. Trajectory calculations of the time of limb crossings were inaccurate at first—the discrepancy being several minutes. Coordinates shown in Figs 2–4 and the local solar time may be in error by up to 30 s on the timescale of Fig. 2, 4 and by up to 3 min on the timescale of Fig. 3.

The highest brightness temperatures on the surface of Phobos were 296–302 K (r.m.s. ± 2K), which is in good agreement with calculations[5]. These were measured in the region with the local solar time 13:15. The lowest temperature for the morning limb did not exceed 200 K.

In the first track Phobos was observed against the background

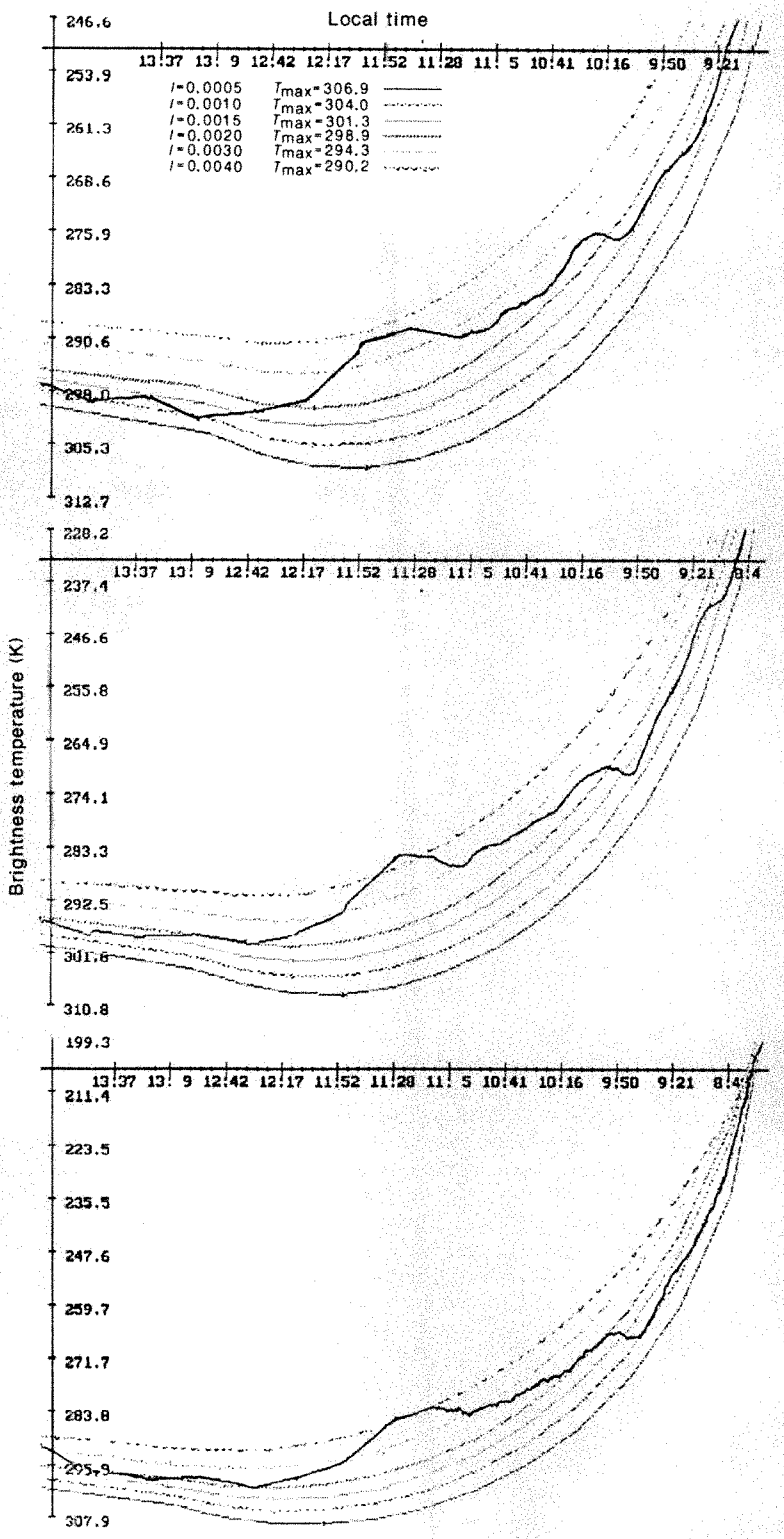

FIG. 3 The comparison of experimental curves of brightness temperature in different radiometer channels (3–5, from top to bottom covering the ranges 7.07–9.57, 9.19–13.83 and 13.70–16.72 μm, respectively) for track I with calculations. The units of thermal inertia I are cal cm^{-2} deg^{-1} s$^{-1/2}$.

of Mars and after crossing the limb the instrument viewed Mars near the local noon. The brightness temperature of Mars in this region was ~263–268 K with the exception of the 15-μm channel where it was lower ($T = 200$ K) because of the absorption of the surface emission by the martian atmosphere. The distribution of points in Fig. 2 after the departure from Phobos may be explained by the detection of radiation from Mars for a time and then from Phobos again, after the spacecraft turned back.

We compared the brightness-temperature curves along the solar local-time axes to calculations. The calculations assumed a flat semi-infinite surface layer[6], using parameters of the solar flux in the function of solar time and the surface albedo. The parameter is thermal inertia $I = (\kappa\rho c)^{1/2}$, where κ is the thermal-conductivity coefficient, ρ is the density and c is the specific heat. The calculated values are shown in Fig. 3. Channel 5 (14.3–15.9 μm) is most convenient because there is almost no distortion of the data as a result of the radiometer detecting radiation from Mars in the Phobos limb observations.

The measurements were made 37 days after the martian spring equinox. The Phobos orbit lies in the equatorial plane of Mars,

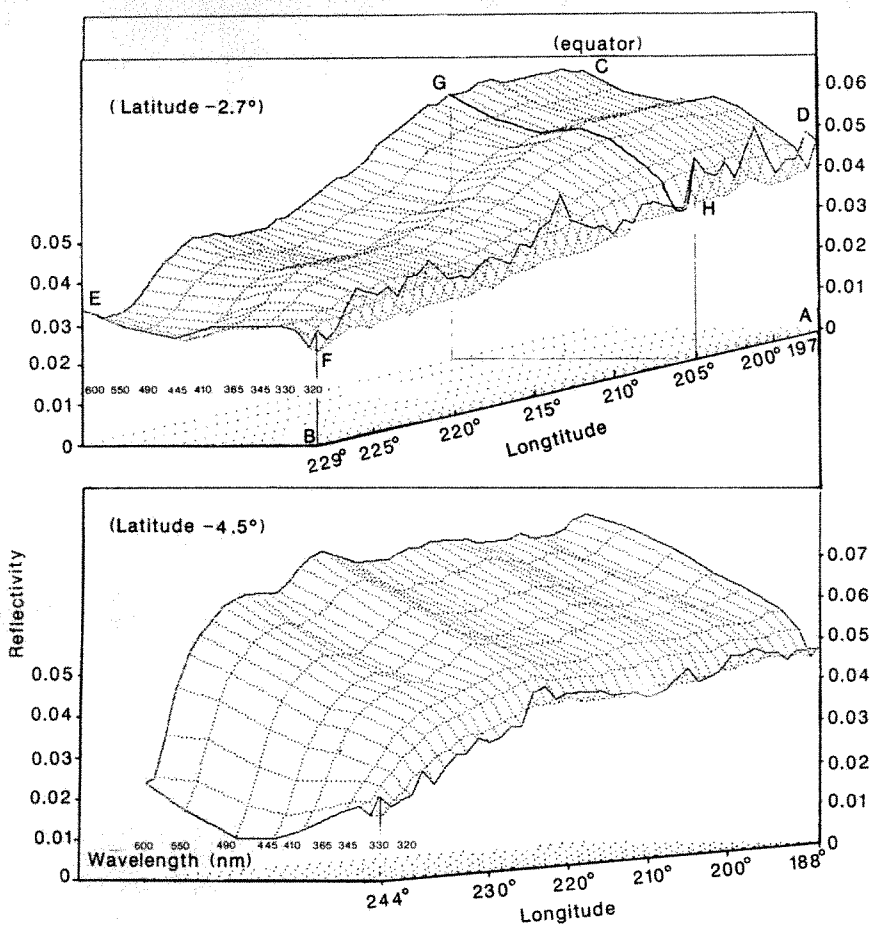

FIG. 4 The reflectivity distribution of the surface of Phobos along track II (latitude −2.7°) and along track I (latitude −4.5°) as a function of wavelength (the line G–H is for 205° longitude) and of longitude along the line A–B. As a result of the small ranges and values of angles (the phase angle was 29°, the solar zenith angle was 21.7°–50° and the spacecraft zenith angle was 3–21°) we did not correct for distortions that result from the viewing geometry.

so at local noon on Phobos the Sun was 6.5° north of the equator, and the heliocentric distance was 1.595 AU. For these conditions the calculated brightness temperature for the layer with $\kappa = 0$ was 310 K. The difference between this model and the observed temperature (~10 K at local noon) is due to the downgoing thermal flux transferred when thermal conductivity is non-zero.

The comparison (Fig. 3) shows that, except for the time interval 10:00–12:00 (longitudes indicated in Fig. 2), the thermal-inertia parameter for the surface of Phobos is close to 10^{-3} cal cm^{-2} deg^{-1} s$^{-1/2}$, which is quite close to the earlier estimates for Phobos[1,4] and the Moon[6]. For some places I was 2×10^{-3} and for the time interval 11:00–11:40 I was as high as 4×10^{-3}. The range of $I = 8\times10^{-4}$–2×10^{-3}, corresponds to fines in the vacuum having mean grain sizes tens to hundreds of micrometres[7], or a higher abundance of coarse material. Even greater values for the 11:00–11:40 time interval could be the result of localized exposures of consolidated rocks or because the layer of fines covering them is very thin. Here the zenith-angle cosine for the Sun is only slightly (7–8%) less than the maximum. The calculations show that the uppermost layer of regolith with the same properties should be only 6 K cooler, not 18 K. The albedo data in Fig. 4 do not show higher reflectivity for this region so the variation of the absorbed solar radiation could not cause this difference.

Because of the short rotation period of Phobos (7 h 39 min 14 s) the depth l_τ of thermal-wave penetration into the Phobos soil is small compared with that of the Moon. For regions with $I = 10^{-3}$, $l_\tau = 0.6$ cm and for $I = 4\times10^{-3}$, $l_T \approx 1.4$ cm.

In the upper and middle panels of Fig. 3 measurements obtained in wavelength ranges 7.2–9.3 and 9.2–13.6 μm are plotted. Because of the high martian temperature at these wavelengths it is difficult to trace the temperature curve at the limb of Phobos. Otherwise, they are of the same shape as for the 15-μm channel.

The photometric properties of the surface of Phobos were also found to be very inhomogeneous. Figure 4 shows the reflectivity-factor distribution of Phobos soil along each of the two tracks for nine spectral bands in the range 320–600 nm. The angular resolution of 15′ produced a spatial resolution of 900–920 m on the surface of Phobos. The field in Fig. 4 is placed in the same way as in Fig. 1 and corresponds to the spacecraft movement along line A–B from right to left.

Along almost the entire length of track I and in the first half of track II the reflectivity increases moderately in the wavelength range 320–600 nm. There are two noticeable decreases in reflectivity along track II at 450 nm and in a rather narrow band at 330 nm. Changes in reflectivity along the track II in 320-nm band (the upper panel of Fig. 4) may be caused by the noise in this channel, the cutoff in spectral sensitivity and/or high amplification. The number of points averaged together (four points for each line of spectra) is the same for both tracks. For all other channels the signal-to-noise ratio was $>10^3$.

The most interesting feature of the track II data is the wide depression: the absorption band between 400 and 600 nm in the longitude range 215°–224°. The same region shows a noticeable decrease in the brightness temperature (Fig. 2). Thus inhomogeneity of the Phobos surface properties is seen in the reflectivity data as well as in the thermal features. Although the identification of the surface composition by reflectivity is difficult, the analysis of combined data (our data and the measurements in the wavelength range 0.8–3.2 μm (the infrared imaging spectrometer experiment[8]) and spectrometric data obtained with the television system[9]) could allow the variations of reflectivity to be related to surface soil composition. □

THE imaging spectrometer ISM, operating in the near infrared, is the first ever flown in space for planetary observation. With a spectral range of 0.76–3.14 μm, its main goals were to obtain information on the mineralogical composition of the surfaces of Mars and Phobos, and on the composition, spatial and temporal variations of the martian atmosphere. The infrared imaging spectrometer ISM acquired 40,000 spectra of Mars and Phobos. Here we present the first results on the surface mineralogy of Mars and Phobos, and the atmospheric composition of Mars.

The first (1.65–3.16 μm) and second (0.76–1.54 μm) orders of the grating spectrometer are separately focused onto two 64-pixel PbS arrays by a dichroic beam-splitter. The resulting resolution is 0.025 and 0.0125 μm per pixel in the first and second order, respectively. The telescope is 2.5 cm in diameter. Imaging is obtained by combining the drift of the spacecraft with the scanning motion of a mirror, which can be moved by up to 20° off the optical axis. The instrument field of view (IFOV) is 12 arcmin. The detectors are cooled down to a temperature of ~200 K by a passive radiator. The sensitivity of the instrument is very high—when observing Mars, the signal-to-noise ratio is 1,000, at 1.8 μm, for an integration time of 0.5 s.

For each resolved area of Mars, or 'spatial pixel', ISM gives an infrared spectrum composed of the 128 data extracted from the PbS detectors. During one sequence of observation, the region mapped has a width that depends on the selected scanning range (1–25 pixels) and a length depending on the duration of the sequence. Here, we refer mostly to the results obtained when the spacecraft was three-axis stabilized. ISM has observed Mars twice from a 'low' altitude (≤ 2,000 km). For these 'high-resolution' tracks, $20 \times 1{,}650\ km^2$, the pixel size is $5 \times 5\ km^2$. The regions mapped extend over the Tharsis Montes, through Pavonis Mons for one track, and through Biblis and Ulysses Paterae for the other track. From the circular orbit, at an attitude of 6,300 km, ISM mapped nine regions with a pixel size of $\sim 20 \times 30\ km^2$. Seven of these regions are located in the western hemisphere, at latitudes lower than 20° and longitudes ranging from 20° to 180°; they map more than 25% of the Tharsis Montes and Valles Marineris area. Two additional regions are located in the eastern hemisphere, within the old cratered terrains south of Arabia Terra for one, Isidis Planitia and Syrtis Major for the other. The total number of spectra obtained exceeds 36,000. They sample most of the major geological formations of Mars, with the exception of the polar caps. The heliocentric longitude of the Sun increased from −4° to 32°, relative to the spring equinox. On 25 March, ISM observed Phobos twice, when the spacecraft was tilted to point towards Phobos from a distance of ~200 km; the resolution achieved by ISM was ~0.7 km per pixel. ISM acquired about 600 spectra: one track of 1×200 pixels, along the equator of Phobos, and a region 20×20 pixels in size, mapping about one-third of the lighted hemisphere.

Below 3.2 μm, the infrared spectrum of Mars originates almost entirely from reflected sunlight. Intense bands are due to absorption by atmospheric CO_2, the strongest being centred at 2.75 μm (Fig. 3). However, it cannot easily be used to monitor the total amount of CO_2 in the atmosphere, because of saturation. Scattering is clearly seen in spectra obtained near the limb. However, scattering does not prevent observation of the surface, even at very oblique thicknesses. All observations were performed at low phase angle. For atmospheric studies, we have selected spectra obtained at a low angle of incidence (<15°). In view of current models of martian hazes, the contribution of scattering in the spectra is expected to be low, especially in the high-altitude range (10–20 km) used for the altimetry measurements described below. Consequently, we have used the 2.0-μm band to evaluate the global CO_2 pressure for each resolved spatial pixel, and derive its altimetry. We made the calculations with a band model in the effective-pressure approximation, using the formulation of Wallace *et al.*[2]. The parameters of the model are the surface pressure, the near-surface temperature and the airmass factor. To achieve the highest accuracy, we analysed 'ratioed' spectra (calculated by dividing spectra obtained at different altitudes) to eliminate instrumental effects as well as the average mineralogical signatures, and we have compared them with the ratios

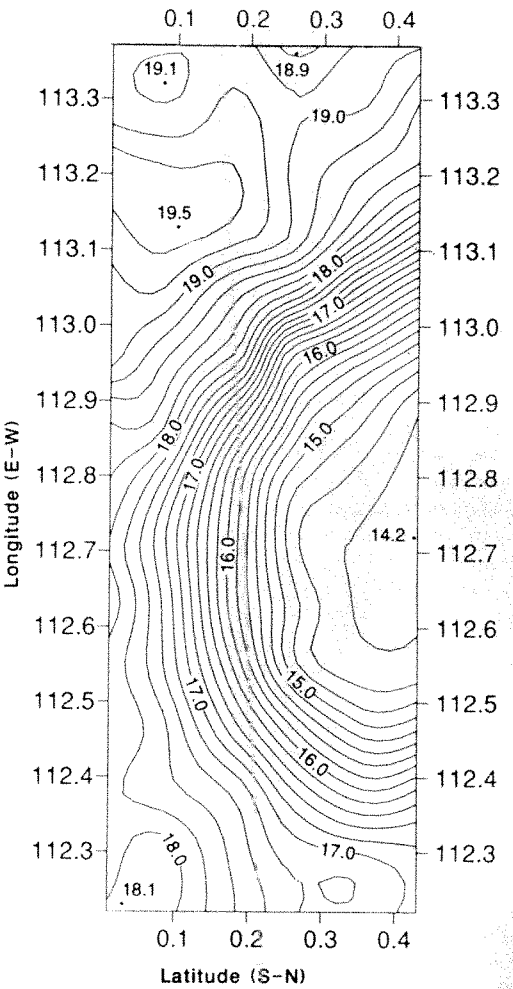

FIG. 1 Altimetry of the caldera of Pavonis Mons, derived from the CO_2 ground pressure. The contour lines are 200-m apart.

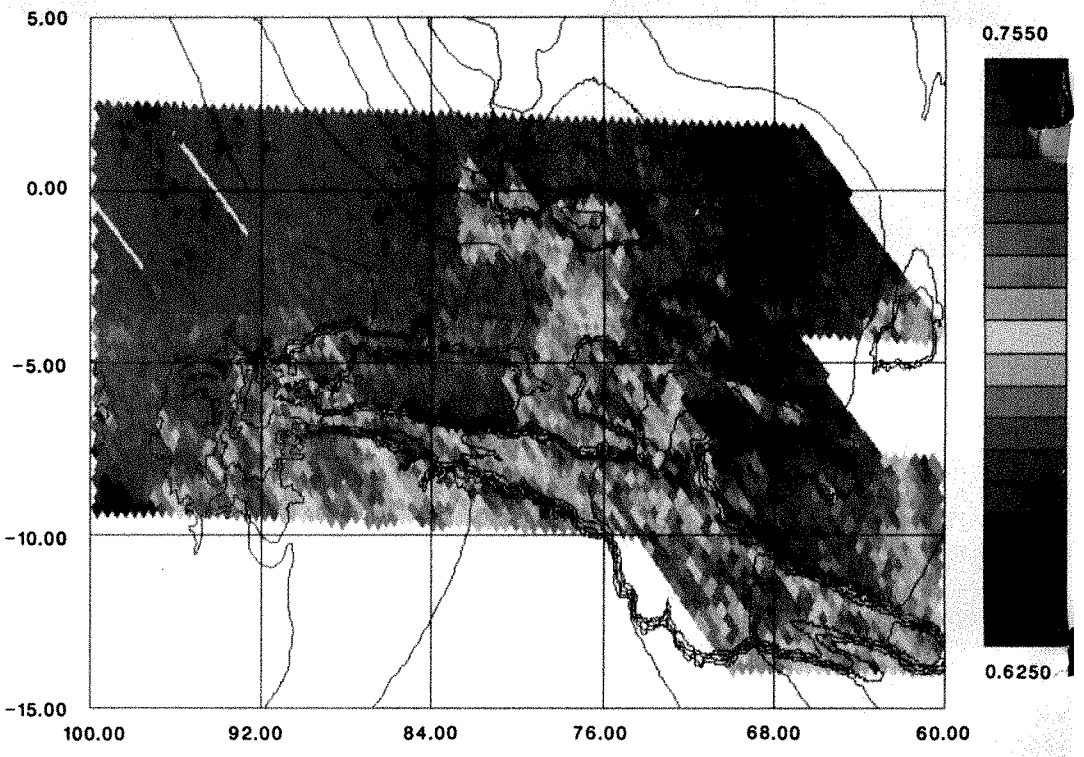

FIG. 2 Variations of the hydration feature in the Valles Marineris region, obtained on 7 March (central part), 12 March (lower right) and 26 March (upper part). The red to blue scale corresponds to an absorption of 25% to 40% at 3 μm.

of synthetic spectra. Figure 1 illustrates the altimetry data derived from a high-resolution track; the caldera of the Pavonis Mons is resolved with a pixel size of ~5 km. We have built a reference spectrum by averaging 25 spectra around the summit. We then chose 90 spectra on a regular grid covering the caldera, and divided them by the reference spectrum. Measuring the altitude at a given point from ratioed spectra requires knowledge of the vertical thermal profile at this point, as well as the altitude and pressure of one reference point. In this preliminary calculation, we assumed the atmospheric temperature at a given altitude to be spatially constant. The thermal profile has been estimated from the Viking IRTM and lander measurements[3,4], with an atmospheric temperature at ground level of 250 K, and a gradient of $-2.0\ \mathrm{K\ km^{-1}}$. The reference altitudes have been estimated from the Viking photogrammetric measurements, with the zero level of the Mariner 9 maps[5]. The altitude of the reference spectrum, near the summit, has thus been taken as 19,000 m. We obtain a depth for the caldera of 5,000 ± 300 m, with respect to the south-west rim. The high signal-to-noise ratio leads to the detection of local topographic features with heights of only 100 m. The determination of absolute altitudes is limited mainly by the reference data derived from Mariner 9, and can be provided with a precision of 5%.

ISM spectra also exhibit the signatures of CO, at 2.35 μm, and H_2O, which was studied from its bands centred at 1.84 and 2.54 μm. To evaluate the amount of these minor species, we selected 15 averaged spectra (each summing 10–30 nearby spectra) at various altitudes on Olympus Mons, from 2 to 26 km.

Ten more spectra were selected in Valles Marineris. For these averaged spectra, the spatial resolution ranges from 50 to 100 km. Assuming a column density of 2.69×10^{19} molecules $\mathrm{cm^{-2}}$ of CO above the summit of Olympus Mons (a value consistent with previous millimetre and infrared observations[5]), and no H_2O at this altitude, we obtained the following results: for CO, a column density of 7.13×10^{19} molecules $\mathrm{cm^{-2}}$ is measured at an altitude of 2 km, corresponding to a ratio for CO/CO_2 of 4×10^{-4}. For H_2O, the ratio of H_2O/CO_2 is 5×10^{-5}, with a factor of 2 uncertainty at different altitudes on Olympus Mons and Valles Marineris. This ratio corresponds to 4 μm of precipitable water (pr-μm), and is compatible with the dry limit of the water measurements of Davies[7], which range from 2 to 60 pr-μm.

The surface of Mars shows large variations in albedo and redness, at a scale corresponding to the resolution of ISM. The average surface reflectance, derived from the reflected flux at 1.1, 1.29, 1.76 and 2.45 μm, ranges from 12% to >40%, for regions observed in the same viewing conditions. These results are consistent with ground-based observations[8], with an increased dynamic range resulting from the improved spatial resolution. The redness of the continuum was derived from the ratio of the fluxes measured at 2.45 and 1.76 μm. As a general trend, bright regions are redder than darker ones. However, marked departures from this correlation are observed, particularly in the region of Valles Marineris.

The ISM spectra of Mars exhibit a broad and intense absorption feature from 2.7 to 3.14 μm. We attribute this feature to the presence of hydrated minerals. To evaluate its strength, we have divided the flux at 3.0 μm (where the CO_2 band is negligible) by that at 2.45 μm, in the continuum. We have then corrected this ratio for the redness. On average, the hydration feature is strong (35% in absorption at 3.0 μm), and exhibits large variations, by up to 20%, on the scale of the spatial resolution of ISM. Figure 2 shows a map of the strength of the hydration

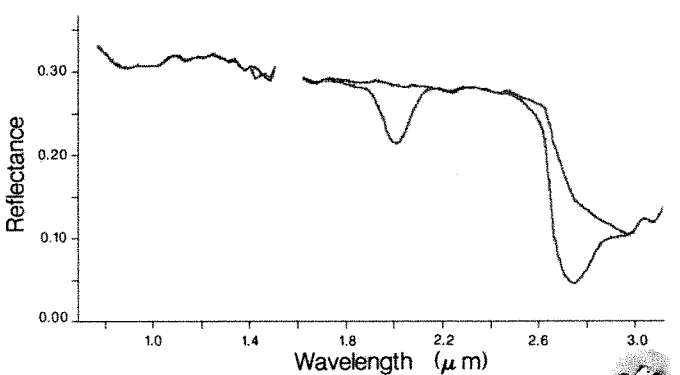

FIG. 3 ISM spectrum of Mars, in Isidis Planitia (red curve). This was obtained by dividing the raw spectrum by the solar spectrum and the instrumental transfer function, deduced from calibrations. After subtraction of features resulting from atmospheric CO_2, the spectrum (green curve) is representative of the martian surface. In particular, the broad band from 2.7 to 3.14 μm is attributed to hydrated minerals.

feature in the Valles Marineris region. When we map the Tharsis Montes volcanoes for their content in hydrated minerals, we also obtain large variations of up to 20%. In particular, when observed at high angles of incidence (50–60°), the slopes of the volcanoes appear systematically enriched in hydrated minerals relative to the much dryer surrounding plateau.

An absorption feature at 1 μm, which probably originates from Fe^{2+}-rich silicates[9], appears in all ISM spectra. Variations in this band, although small in general, are observed in most mapped regions. Processing the entire set of calibration data will, however, enable us to derive an instrumental transfer function for the 0.8–1.2-μm range, with sufficient accuracy to attribute unambiguously a given spectrum to the silicate composition of the surface.

The preliminary analysis of the two data sets on Phobos shows that the albedo of Phobos is about four times lower than that of the Tharsis Plateau surrounding Pavonis Mons, and that the hydration signature is much weaker on Phobos than on Mars. Both the very low albedo and hydration indicate a relationship with the most evolved carbonaceous chondrites (C4), rather than with the water-rich ones (C1 and C2). On a kilometre scale, the hydration and silicate features exhibit variations of up to 10%.

Although the Phobos 2 mission ended prematurely, ISM acquired a large number of spectra of Mars, sampling most of the major geological formations. The high sensitivity of ISM should provide very valuable data on the atmosphere and surface of Mars, with a resolution of a few tens of kilometres. The ISM observation of Phobos constitutes the first spectral imaging of a small body. Heterogeneities are observed on a kilometre scale, which should yield insights into the origin and evolution of Phobos. □

THE aim of the Thermoscan experiment on the Phobos spacecraft is the further study of the thermal properties of the surface of Mars that was begun by the Soviet Mars spacecraft and the Mariner and Viking spacecrafts. These previous investigations obtained data concerning the temperature distribution in different areographic regions, the evaluation of daily and seasonal changes of the planet temperature, and the thermal inertia of the martian surface. Previous data had a spatial resolution of a few tens or a few hundreds kilometres; in particular, the resolution of the data collected by Vikings 1 and 2 is 8–175 km. The Thermoscan experiment provides thermal images of far higher resolution, giving more comprehensive data on the temperature distribution and thermal inertia of the surface of the planet and its relief elements and making it possible to search for small thermal anomalies.

Multispectral scanning is the best technique for the physical interpretation of the data obtained, providing the simultaneous detection of the brightness temperature of the sighted region and its reflectance properties, which determine the heating of the surface by the Sun's radiation.

The Thermoscan radiometer operates in two spectral bands: 8.5–12 μm and 0.5–0.95 μm. The line-by-line scanning is achieved by means of a mirror oscillating in a stepwise fashion, perpendicular to the spacecraft motion velocity; the frame scanning is accounted for by the motion of the spacecraft itself.

The instantaneous field-of-view value in both channels is 0.9 arcmin, the scanning angle 6.1° and the scanning rate 1 line per s. It provides a resolution at nadir of 1.8 × 1.8 km and a swath length of 650 km from the circular observational orbit of 6,300 km. The area traversed in the direction of motion is a function of the length of the session. To provide the radiometric measurements during the scanning process, the instrument is calibrated relative to inner reference radiators and space. The fore optics are included in the calibration with the exception of the scanning mirror. The Thermoscan thermal response characteristic is shown in Fig. 5. The first session scanning the surface of Mars was conducted on 11 February, 1989 from the intermediate elliptical orbit, which was the transfer stage to the circular orbit. This orbit provided a unique opportunity to observe from altitudes lower than that of the circular orbit, (in the range from 1,150 to 5,200 km). From these altitudes, a surface resolution of 300 m was obtained. Figure 1*a* presents the scanning geometry in this session.

The scanning was conducted under conditions of uninterrupted astro-solar spatial attitude control of the spacecraft. Moreover, the axis-of-sight position in the centre of Thermoscan line is aligned with the solar-ray direction. During scanning, the distance from the spacecraft to the planet surface and the velocity of the subsatellite point were varied. As a result, changes in

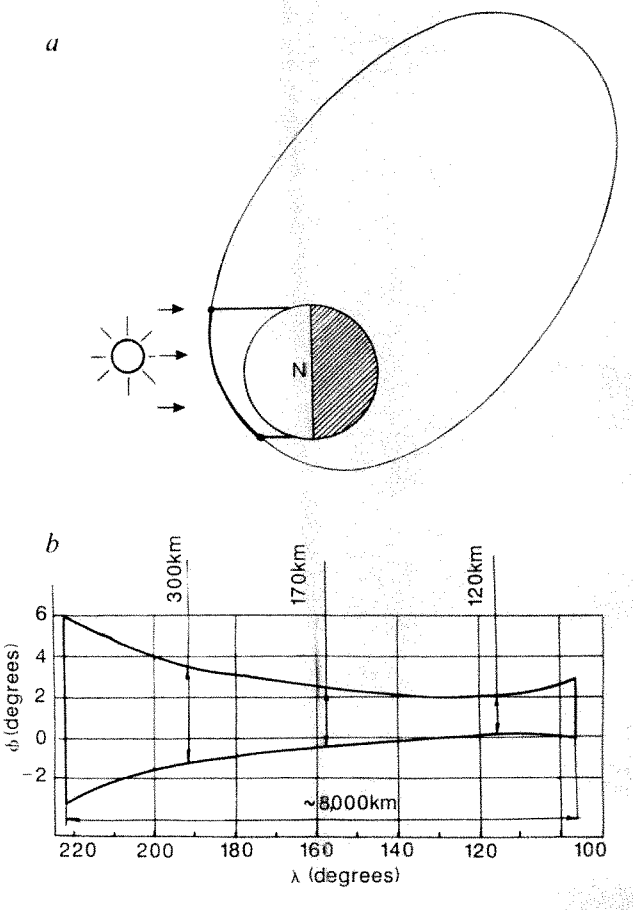

FIG. 1 Scanning geometry in the session of 11 February 1989. *a*, Position of the spacecraft in scanning session. *b*, The areographic coordinates of the scanned area.

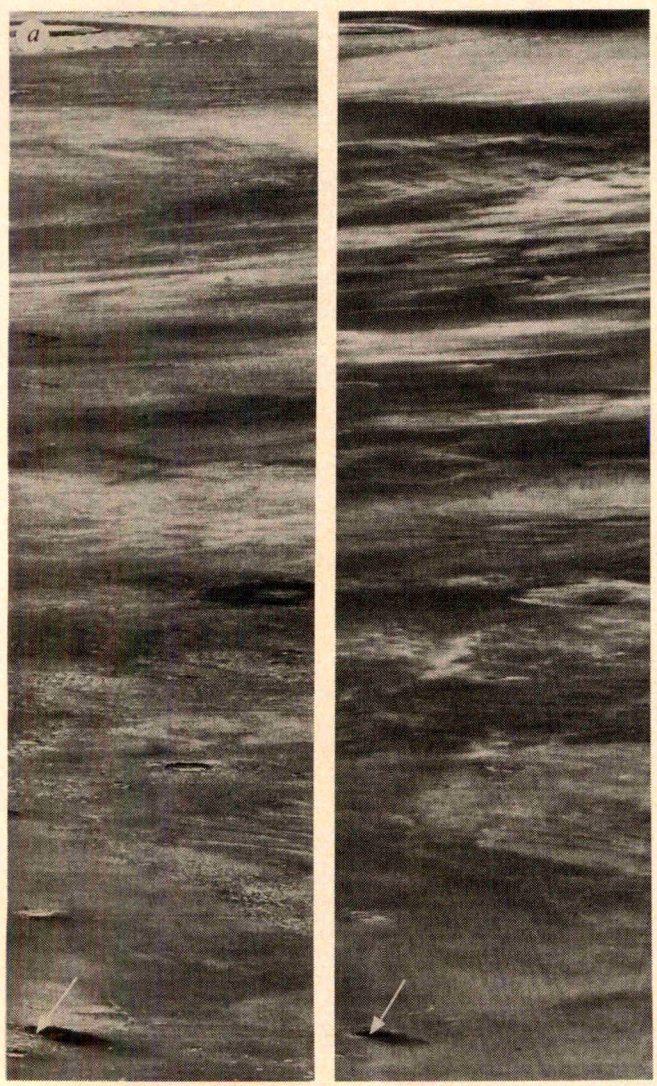
dimensions of the area traversed in the line direction and in line and frame resolution occurred.

Temperature profiles on the surface with gaps between them were obtained. The gaps have variable sizes due to variations in subsatellite point motion velocity. The image synthesis here, therefore, causes a number of significant geometrical distortions to appear. Nevertheless, after completion of the partial geometrical correction, images of high quality have been obtained. Figure 2*a* shows the image fragments: 8.5–12 μm; 0.60–0.95 μm. The areographic coordinates (λ-longitude, φ-latitude) and local time of the scanned area are presented in Fig. 1*b*.



The zenith angle of the Sun during the scanning process varied from 10° to 90° and then to 20°. The seasonal conditions of the scanning experiment correspond to the astronomical martian spring (areocentric longitude of Sun, $L_S = 357°$). The scanning was conducted in near-equatorial, light and flat areas (the regions Elysium Aeolis, Amazonis, Memnonia, Tharsis), characterized by the existence of fractures of relief and relatively few craters of meterorite origin. At the end of the session, one of the highest martian mountains, Pavonis Mons, with the volcanic crater on the peak, fell within the instrument's field of view.

Figure 3 illustrates the scanning geometry for the circular orbit (on 1 March 1989 at an altitude of 6,300 km). The line and frame scanning are matched, and the geometrical distortions during the scanning accompanied by the continuous astro-solar control of the spacecraft spatial attitude, arises only because of planet sphericity. Because of this condition and as a result of intricate terrain relief and the marked inhomogeneity of the reflectance characteristics in the scanning area, images received in the second session contained more data. Fragments of these images are shown on Fig. 2*b*. The areographic position and local time of the scanned Mars area is shown in Fig. 3*b*. The zenith angle of the Sun during the scanning varied over a narrower range than in the first session (from 55° to 90° to 30°). Seasonal conditions were the same as in the first session ($L_S = 6°$).

The scanning area covers the near-equatorial zone with a host of craters (regions Oxia Pulus, Mapgapitifer Sinus, Apabia, Sinus Sabarus) and with multiple relief forms: such as erosive form, fractures twisting valleys and so on.

Beside these distinctions, the images obtained during two sessions have much in common with each other. The contrast of the thermal images on the whole scanning route is higher than in the short-wave range because of the lower dependence of the thermal contrasts on the Sun's position during scanning. A no-shadow condition in the visible spectrum gives rise to diminished contrast in channel 0.6–0.85 μm and allows the surface reflectance to be determined in that spectral range.

Examination of the images in both channels, obtained in both sessions, shows diverse examples of direct and inverse correlations of the brightness temperature with reflectance of the surface areas; that is, the darker regions are hotter and vice versa

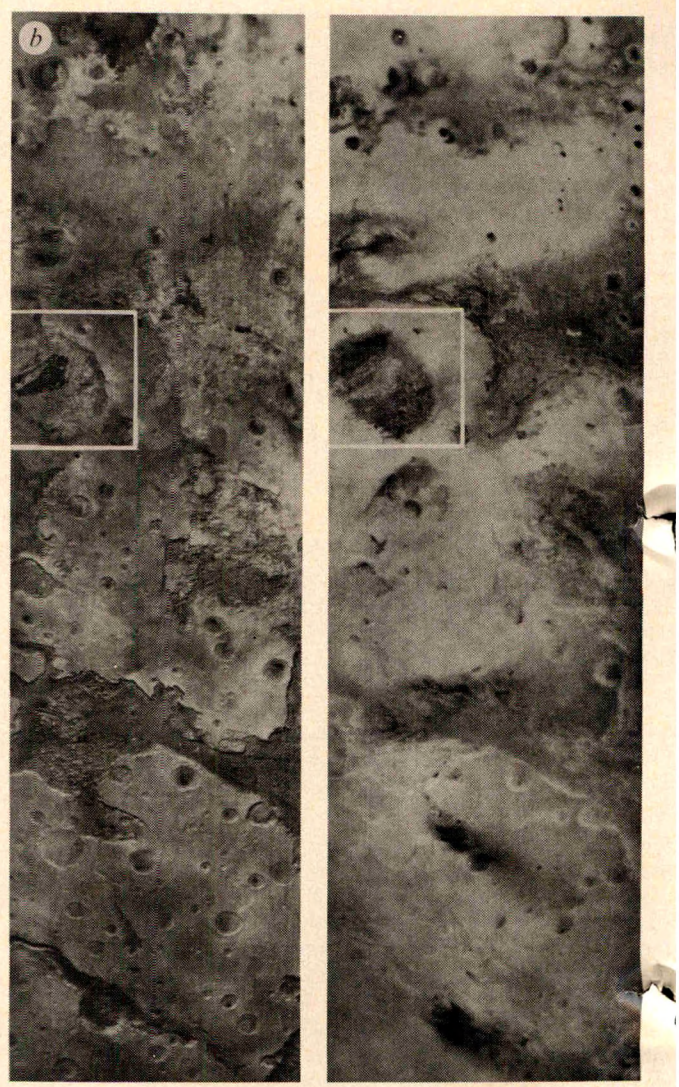


FIG. 2 *a*, The Mars surface-image fragments in the session of 11 February, 1989. Left, spectral band 8.5–12 μm; Right, spectral band 0.6–0.95 μm. *b*, The Mars surface image fragments in the session of 1 March, 1989. Left, spectral band 8.5–12 μm; Right, spectral band 0.6–0.95 μm.

contrast inversion). This is probably caused by several factors such as thermal properties of the soil, surface-layer structure, and relief geometry. We now consider some examples of selected areas in the image fragments. The crater interior, marked by the arrow on Fig. 2*a*, is darker in the visible spectrum and, colder in comparison with the surrounding surface. Such a combination of signals could stem from the relief geometry or thermoinertial properties of the soil. The local dark surface region, lying southwest of this crater and having a lower brightness temperature, is of great interest. It can be said with confidence that it is an area with increased thermal inertia[8]. The observed temperature differences are equal to 20–25 K. Unlike this inverse correlation of temperature/brightness, the depression zone and its

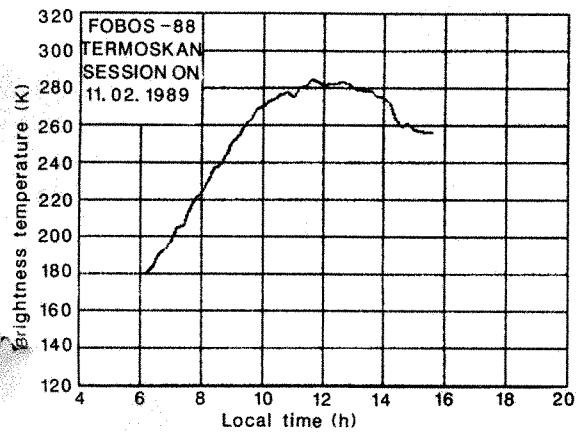

FIG. 4 Diurnal variations of the brightness temperature in the session of 1 February 1989.

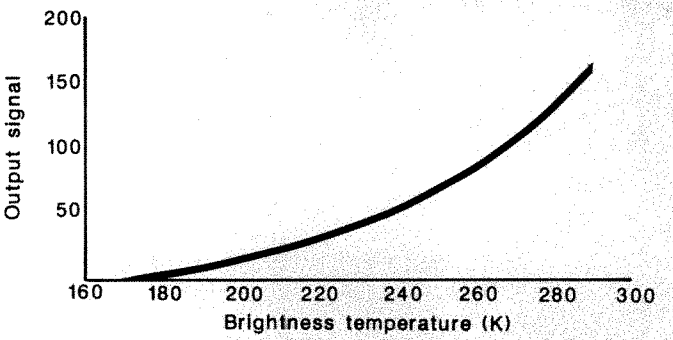

FIG. 5 Thermal response characteristic of Thermoscan.

peripheral portion (enclosed in frame on Fig. 2*b*), illustrate the direct correlation: the darker regions have elevated temperatures relative to the light regions (temperature difference is 10–15 K). During both scanning sessions the observed brightness temperatures on the whole route range from 180 to 280 K (see Fig. 4), which agrees with the previous observations and models[1–7,9,10]. New information is acquired concerning the temperature differences of separate, closely situated terrain details which reach 20–30 K.

The data presented here should be regarded as preliminary. The rich experimental information, newly gained thanks to the high spatial resolution of the Thermoscan device, demands further analysis.

After finishing the work on this article, two more sessions scanning the surface of Mars were carried out (26 March, 1989), in one of which the Phobos shadow image on the surface of Mars is visible and thermal spectral bands were obtained. The appropriate information will be given in subsequent publications. □

Determination of the elemental composition of martian rocks from Phobos 2

Yu. A. Surkov, V.L. Barsukov, L. P. Moskaleva, V. P. Kharyukova, S. Ye. Zaitseva, G. G. Smirnov & O. S. Manvelyan

V. I. Vernadsky Institute of Geochemistry and Analytical Chemistry, Academy of Sciences, Kosygin Street 19, 117975 Moscow, GSP-1, USSR

PREVIOUS orbiter and lander pictures have given an indication of the general morphology of the surface of Mars and of some relatively small features on the surface. Here we have determined the elemental composition of martian soil from Phobos 2 using orbital γ-ray spectrometry. This technique is used to analyse the surfaces of planets which either do not have an atmosphere or which have only a low-density atmosphere (that is, there is negligible absorption of γ-rays). The γ-radiation is caused by the decay of radioactive elements excited by the interaction of solar (SCR)

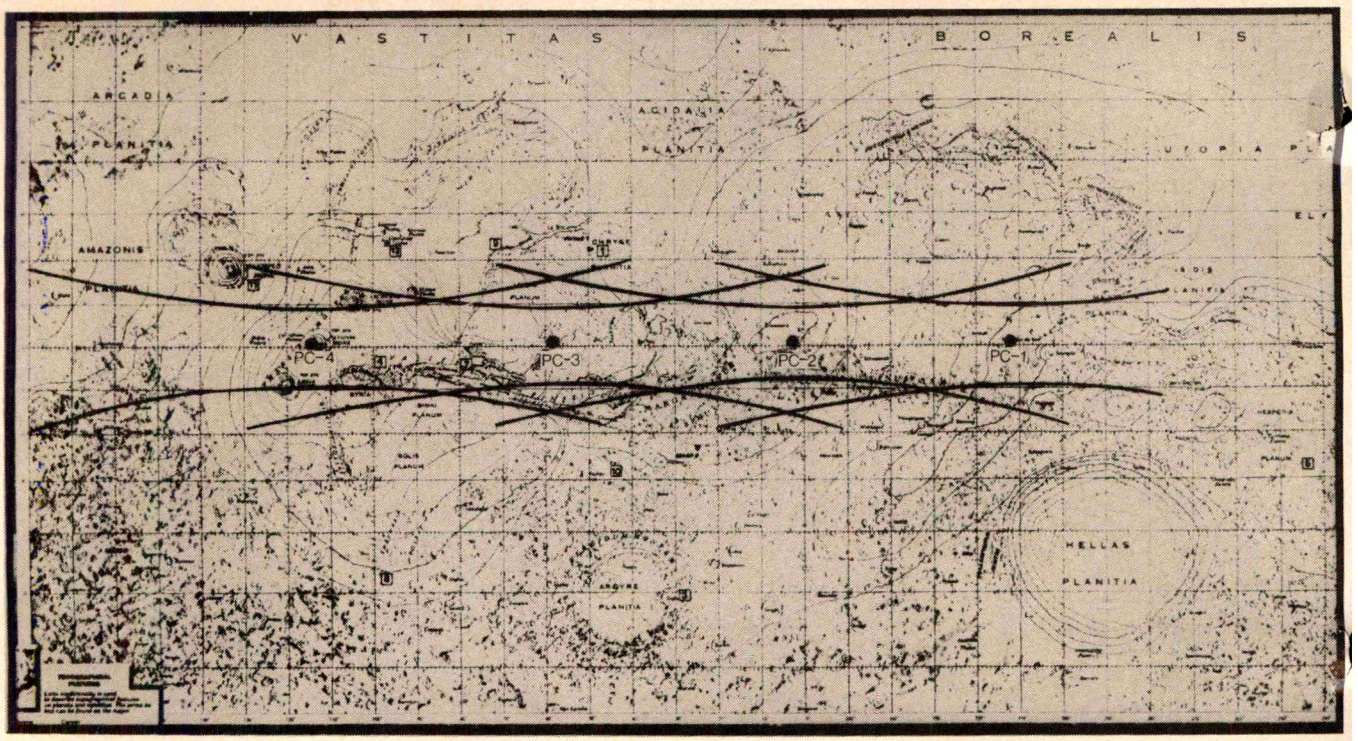

FIG. 1 Map of Mars indicating the regions where γ-radiation was measured.

and galactic (GCR) cosmic rays with the surface materials. Measurements of this radiation by a γ-ray spectrometer enable the elemental composition of the near-surface rocks to be determined. The first successful measurements of γ-radiation were conducted from Luna 10 (ref. 1). The method was used subsequently during studies of the Moon from Apollos 15 and 16 (ref. 2), and Mars 5 (ref. 3).

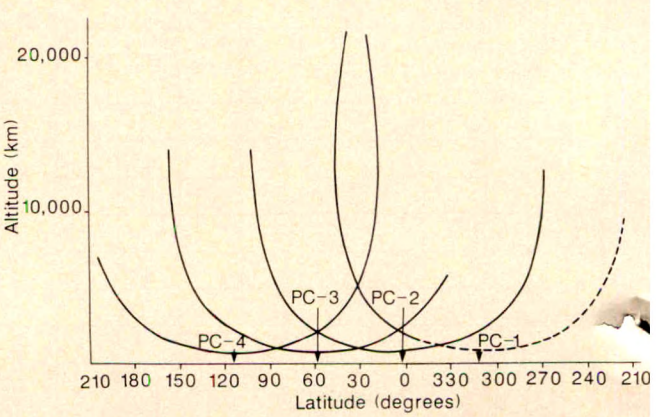
To measure the γ-radiation of Mars the Phobos spacecraft was provided with a γ-ray spectrometer with a 100×100 mm CsI(Tl) crystal. This γ-ray spectrometer was more efficient than those used earlier. The energy range was 0.3–10.0 MeV. The energy resolution of the detector (with respect to Cs^{137}) was 10%. The analyser had 512 energy channels, each with a capacity of 2×10^{16} bits. Power consumption was 13 W. The mass of the device was 12.5 kg. The device consists of three units: an outrigger detection unit, a multi-channel pulse-height analyser and an electronic unit. The optimum temperature conditions for the operation of the γ-ray spectrometer are achieved by using a heater with a thermoregulator.

In γ-ray spectrometry, the analysis of background γ-radiation sources and the reduction of their contribution to the spectrum that is being recorded are of great importance. The background radiation is caused by the decay of naturally radioactive elements that are part of the structural materials of the γ-ray spectrometer and the spacecraft, and by nuclear interactions of cosmic rays with these materials. To reduce background radiation the device must be installed as far away as possible from the main mass of structural materials of the craft. On Phobos 2, the detection unit of the γ-ray spectrometer was placed on the solar panel at a distance of 4 m from the craft's centre.

The contribution of various components of the background radiation to the spectrum being recorded differs for measurements taken close to the planet's surface and those taken at large distances from it. In measurements taken at the planet's surface, the background contribution due to the interaction of GCR with the material of the spacecraft and the γ-ray spectrometer decreases because of screening by the planet of a portion of GCR, but a flux of γ-quanta emerges. This flux is initiated by reactions of secondary neutrons with the structural materials of the spacecraft and the γ-ray spectrometer.

Background γ-radiation comes from the planet's surface and is caused by processes such as the decay of π-mesons, initiated by GCR in the planet's atmosphere and soil, γ-bremsstrahlung, the Compton effect, and so on. Such a complex background makes it impossible to exclude it in spectra measured above the martian surface, by the direct subtraction of the background measured on the Earth–Mars route. The identification of the contribution of different processes in the spectrum is required. For this purpose the detector's own background was measured in the low-background chamber at the pre-flight stage of the experiment, and statistical measurements of background spectra were repeatedly carried out on the flight route and on the sections of orbits lying far from the martian surface. These measurements have made it possible to analyse the dynamics of the change of the contribution of various processes to background radiation.

In January 1989, Phobos 2 reached Mars and was injected into orbit. For about three weeks the spacecraft was in a three-



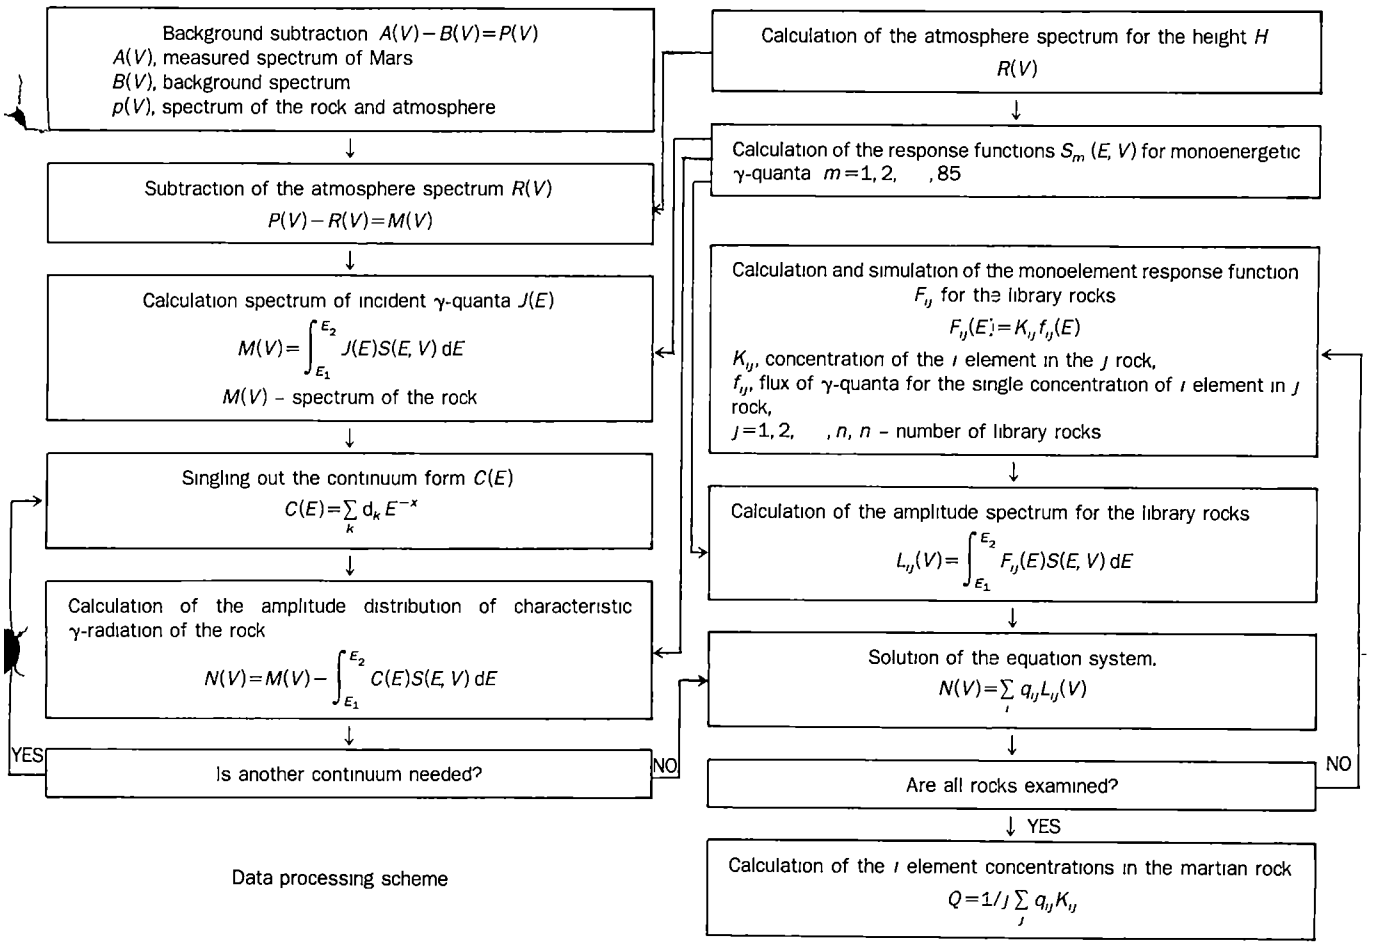


FIG. 2 Sections of the flight trajectories PC-1 to PC-4 of Phobos 2 in the vicinity of Mars on which measurements of γ-radiation were conducted.

Data processing scheme

day elliptical orbit with a minimum and maximum distance of ~870 and ~80,000 km from the surface of the planet. The craft's orbital plane was inclined to the equatorial plane by 1°. At this stage the planet's γ-radiation was measured when the spacecraft approached the surface (in the perigee region). At the maximum distance the background radiation was measured.

Figure 1 presents a map of the martian surface. It indicates regions where the γ-radiation was measured. Points PC-1, PC-2, PC-3 and PC-4 correspond to the places where the craft was closest to the surface of Mars. Envelopes around these points are indicated. They show the limits of the planetary surface area from which 50% of the γ-radiation was collected.

Figure 2 shows sections of the craft's trajectory on which measurements were made. As can be seen from the figure, measurements of γ-radiation were started at a distance >5,000–10,000 km, then were conducted at closer distances and, finally, were completed when the craft flew away from the martian surface at a distance >5,000–10,000 km. Measurements of each γ-spectrum lasted ~10 min. Figure 3 presents a martian γ-ray spectrum measured in the PC-3 region.

Here we summarize the results of analysis of the γ-spectra measured on the lowest sections of the PC-3 orbit. The general diagram of data processing is presented in the scheme below. Analytical results are included in Fig. 3 legend; errors given are due to statistical uncertainties of measurements and uncertainties in singling out the continuum, solar and galactic ray fluxes, matrix effects that depends on the chemical composition of the rock. The errors were calculated as the r.m.s. deviation of the different solutions of the equation $N(V)=\sum_i q_{ij}L_{ij}(V)$ from the average (see block diagram).

We started processing from this particular rendezvous session because during this session the spacecraft explored the region situated close to that which was studied from Mars 5 in 1974. The elemental composition of the martian rock in the PC-3

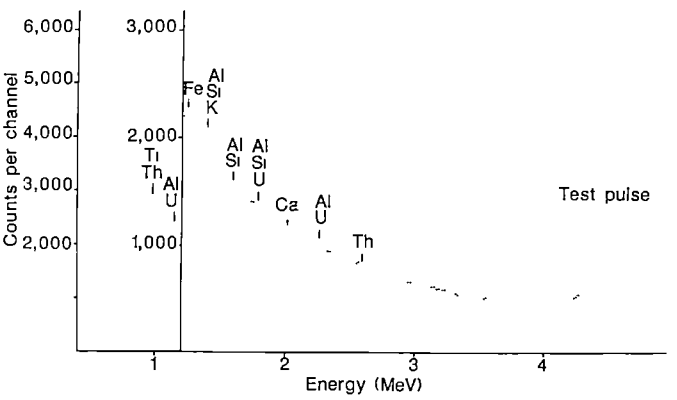

FIG 3 Gamma-ray spectrum measured on the PC-3 trajectory at the closest distance to Mars. The measurements took 1,800 s; this time corresponds to an interval of 102°–15° latitude The martian rock composition is:

Element	Phobos 2 (%)	Mars 5 (%)	Viking 1 (%)	Viking 2 (%)
O	48±5	44±5	501±43	504
Mg	6±3	—	50±25	—
Al	5±2	5±2	30±09	—
Si	19±4	14±3	209±25	200
S	—	—	31±05	26
Cl	—	—	07±03	0.6
Ti	1±05	—	0.51±02	061
K	03±01	03±01	025	025
Ca	6±3	—	40±08	36
Fe	9±3	14±4	127±20	142
U	$(05\pm01)\times10^{-4}$	$(0.6\pm01)\times10^{-4}$	—	—
Th	$(19\pm0.6)\times10^{-4}$	$(21\pm0.5)\times10^{-4}$	—	—

regions relates to a relatively large area incorporating the regions of Lunar Planum and Xanthe Terra. It is therefore hard to relate the composition to a specific geomorphological province.

For comparison, we also present the contents of the basic rock-forming elements obtained from Mars 5 (ref. 3) and Vikings 1 and 2 (ref 4). We calculated the oxygen concentration following a similar procedure to that used for determining the concentrations of the other elements. The atmospheric oxygen content was accounted for in the calculation of the atmospheric spectrum (see block diagram).

The similarity between the rock composition in the PC-3 region and the rock composition measured from Vikings 1 and 2 allows us to conclude that vast territories on the martian surface are covered with the aeolian deposition layer.

Because Phobos 2 explored a thicker rock layer than Vikings 1 and 2 we assume that the composition derived for PC-3 reflects a mixture of surface material and the underlying bedrock. In this connection the possible compositions of the bedrock can be calculated proceeding from different contributions of both components (Yu. Surkov, personal communication). The closest analogue of the rock on Earth was determined on the basis of the systematics of magnetic terrestrial rocks, and has been found to be subalkaline basalt occurring on oceanic islands.

These, then, are the first, preliminary results of analysis of γ-ray measurements from Phobos 2. At present, data processing is in progress. It might be possible to reveal considerable differences in the composition of the bedrock lying in the different regions of the martian surface that have been explored. Of particular interest are spectra measured during the spacecraft's fourth encounter with the planet's surface, when measurements were conducted over the volcanic province of Tharsis. At the moment of closest rendezvous the craft was over the giant Pavonis volcano. Also of interest are other regions representing a great diversity of geomorphological structures on the martian surface. However, further time is required for detailed processing of the data obtained. □

THE study of γ-ray emission from planets with a thin atmosphere allows a rough estimation of the chemical composition of their surface to be made. The first attempt to make orbital measurements of the γ-ray flux from Mars was made by the Soviet spacecraft Mars 5 (ref. 1). Here we present results from the γ-ray APEX experiment on board Phobos 2. We have measured the γ-ray albedo of the martian surface. This albedo appears as a large continuum between a few hundred keV and 8 MeV corresponding to a source intensity of 5 photons $cm^{-2}\ s^{-1}\ 2\pi^{-1}$ (estimated in the 150–1500 keV energy range). There is also evidence for a 511-keV annihilation emission and for a broad contribution of probable nuclear lines between 4 and 7 MeV.

The APEX experiment was designed primarily to record the temporal variations and the spectral characteristics of cosmic γ-ray bursts and solar flares in the 60 keV–9 MeV energy range with a fine-time resolution. However, this instrument also performed detailed γ-ray measurements when Phobos 2 was close to the martian surface. We report here preliminary results obtained near the periapsis of four successive elliptical orbits.

The APEX instrument consists of a detector built in the Soviet Union[2] with the electronics supplied by France. The detector is a 10×10 cm cylindrical CsI(Tl) crystal fixed at the edge of a

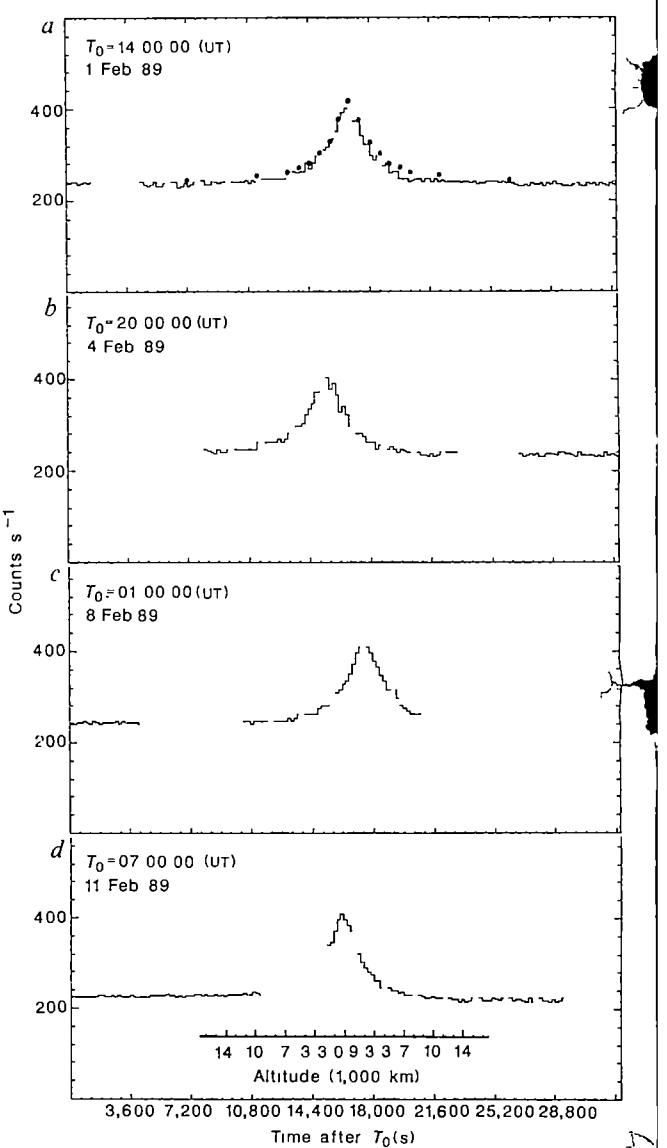

FIG. 1 Count rate through the pericentre passages in the integral channel 150–1,500 keV: *a*, *b*, *c* and *d* correspond to pericentre numbers 1, 2, 3 and 4. In the upper left corner Time (UT) is given corresponding to the beginning of the time axis. In the top panel *a*, expected signal variation is also indicated by dots. The inset *x*-axis on the bottom panel shows the altitude above surface.

solar panel to cover a large field of view (~4π sr at >300 keV). Its relative energy resolution (∂E(FWHM)/E, where FWHM is the full width at half maximum) is 11% at 0.662 MeV, 7.1% at 2.0 MeV, and 5.4% at 6.0 MeV. The total efficiency exceeds 0.80 in the whole energy range. The platform-mounted electronic circuit uses the capabilities of an 80C86 microprocessor to store data in coarse and fine-time resolution modes both for temporal and spectral records. The fine-time resolution mode is selected either automatically through the detection of a significant count-rate excess or by telecommands. It authorizes the recording of 116 consecutive spectra, over 108 energy channels, with a fixed number (chosen by command) of accumulated counts between 150 and 1,500 keV for each individual spectrum.

On arrival near Mars, Phobos 2 was injected into an elliptical orbit[3] with a period of 3.23 days, and altitudes above the surface at apocentre and pericentre of 79,300 and 860 km, respectively. The orbital plane was very close to the martian equatorial plane. The spacecraft followed this orbit for 4 complete revolutions before a correction of trajectory. The background count-rate was measured continuously. Close to each pericentre, the on-board software triggered 16 periods of ~9 min duration with a fine-time resolution mode for a detailed analysis of the γ-ray emission from the planet surface. This sequence was spread over 4 h centred approximately at the pericentre time. The corresponding dates, times (UT), altitudes and areographic longitudes are given in Table 1.

As shown in Fig. 1, for each pericentre passage, the count rate integrated between 150 and 1,500 keV is clearly influenced by the planet. Far from the pericentre time the total γ-ray background is steady at ~240 counts s^{-1}. At ~1.2 h before the pericentre time, corresponding to an altitude of ~8,000 km, a gradual increase of the count-rate is observed in each pericentre approach up to a maximum of ~410 counts s^{-1}. The count-rate then returns symmetrically to its steady level. This increase, by a factor 1.7, is probably due to the planetary albedo which, in γ-rays, consists mainly of a continuum produced by the scattering of the nuclear emissions generated either by the natural radioactivity or by the bombardment of cosmic-ray particles into the nuclei of the constituents of Mars.

TABLE 1 General characteristics of pericentre passages

Pericentre no	1	2	3	4
Date (1989)	1 Feb.	5 Feb.	8 Feb.	11 Feb.
Time (UT)	18:39:37	00:15:47	05:51:58	11:28:12
Altitude (km)	867	859	850	842
Longitude (deg)	310	4	59	113

As the APEX electronics does not discriminate between particles, we cannot exclude a neutron contribution. Let us assume that the count-rate increase is due to the total albedo emission; in this case, it can be verified that the temporal variation of the flux is only a geometrical effect dependent on the altitude. This is illustrated in Fig. 1 by the good agreement between the observed data obtained during the first pericentre passage and the points (large dots) deduced from this geometrical calculation, assuming that the albedo source is located above the atmosphere at an altitude of 120 km. From this dependence, it is easy to relate the measured count rate to the source intensity. If the additional count rate (~170 counts s^{-1}) at pericentre is due to the γ-ray albedo only, and using a value of ~80 cm^2 for the detector area and 0.9 for the total efficiency in the 150–1,500-keV range, the estimated source intensity is of the order of 5 photons (cm^{-2} s^{-1} $2\pi^{-1}$) in this energy range.

For a better understanding of the planet's characteristics, more information can be extracted from the spectra. A total spectrum including 116 individual spectra during the fourth pericentre passage is shown in Fig. 2 with 1σ errors bars. The measurement period started at 11:27:30 UT on 11 February 1989, that is 42 s before the pericentre time, and lasted 487 s. A cosmic spectrum normalized to the same duration, measured 1 h after the pericentre passage (between 12:27:09 and 12:36:50 UT) is plotted below the total spectrum for comparison and will be used as a background reference. The line near 4.5 MeV is due to the internal calibration source.

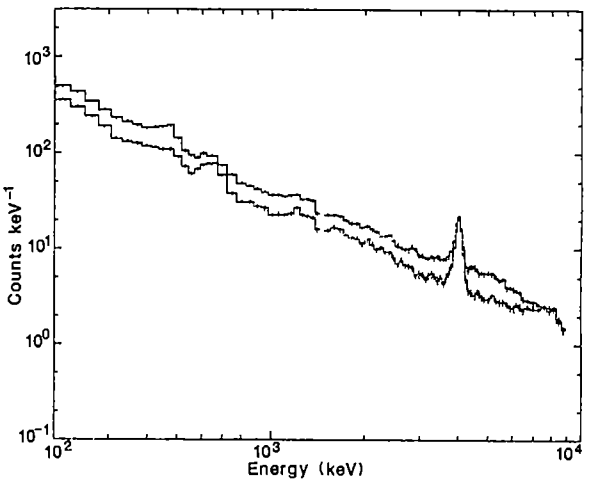

FIG. 2 Total spectrum registered at pericentre number 4. A spectrum measured 1 h later is plotted below for comparison. The line near 4.5 MeV in both spectra is caused by the internal calibration source.

This figure clearly shows that the emission from the planet covers an energy range from a few hundred keV to 8 MeV. There is no contribution above this upper limit as expected from predominantly γ-ray-induced emissions[4]. Another characteristic of the spectrum is that it is almost parallel to the background spectrum. Here again the increase factor is of the order of 1.8. Some features are observed above the continuum: a clear line at 511 keV corresponding to the annihilation process and some features due to the CsI crystal activation (mainly at 0.7 and 1.4 MeV in iodine). The fact that the activation peaks are not stronger in the pericentre spectrum seems to indicate that the neutron albedo does not contribute a large fraction to the observed increase of the count rate.

The particular contribution of the planet is obtained by subtracting the background spectrum from the pericentre spectrum (Fig. 3). It is clear that this additional signal consists mainly of a continuum. The only evident feature is the peak at 511 keV

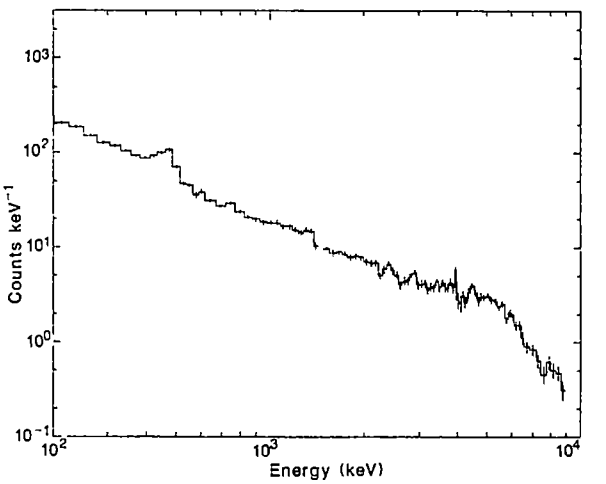

FIG. 3 Spectrum of the Mars planet contribution measured at pericentre 4. It shows a continuum above which an annihilation line contribution is seen at 511 keV and a broad contribution of probable nuclear lines between 4 and 7 MeV.

from the annihilation process. This line may be partly produced locally within the spacecraft body and the detector itself through albedo interactions, but it is also due to annihilation in the martian atmosphere and the surface. The relative amount of each possible line component will be established after a more careful study of the processes involved. Another important feature is the cutoff at 6 MeV with no significant contribution of the planet above ~8 MeV. However, as the count-rate spectrum in Fig. 3 tends to a constant level below 200 keV, the photon spectrum must be mainly above this value because the Compton effect is the dominant interaction in the detection process. This is similar to measurements of the lunar γ-ray albedo of which the energy spectrum is limited in the range from a few hundred keV to ~8 MeV (ref. 5).

When looking more carefully at Fig. 3, it seems that there is a 'shoulder' in the spectrum between ~4 MeV and ~7 MeV. This may indicate a possible mixed contribution of individual lines produced in the surface of Mars such as oxygen (lines at 4.438, 6.129, 6.917 and 7.117 MeV), iron (lines at 7.631 and 7.645 MeV), silicon (line at 4.934 MeV) or titanium (line at 6.762 MeV). The moderate energy resolution of the detector, the importance of the Compton effect in the detection process, as well as the role of the escape peaks and the bremsstrahlung process, makes line identification difficult. Further analysis needs an accurate procedure to unravel photon spectra from count-rate spectra. This task is under way. As this experiment allows a fine-time analysis, some temporal evolution already seen in the observed spectra may appear to originate in the longitudinal variations. If this hypothesis is confirmed, it will be possible to obtain information on the regional variability of the martian surface composition. □

THE most sensitive parameter in a chemical model of the martian atmosphere is the vertical profile of ozone concentration, which has not previously been measured. Solar occultation measurements performed on the Phobos 2 spacecraft in martian orbit have provided us with such profiles, together with evidence for the existence of particles of small dimensions (0.1-μm diameter) in the 50- to 20-kilometre altitude range. These particles could be H_2O ice at the top of the observed range and dust at lower altitudes, possibly haematite, with a wide range of dimensions (down to nanocrystal size), dispersed in some other material (H_2O ice or silicates, for example). The relatively large number of these solid particles opens up the possibility of heterogeneous chemistry having a major role in the atmosphere of Mars.

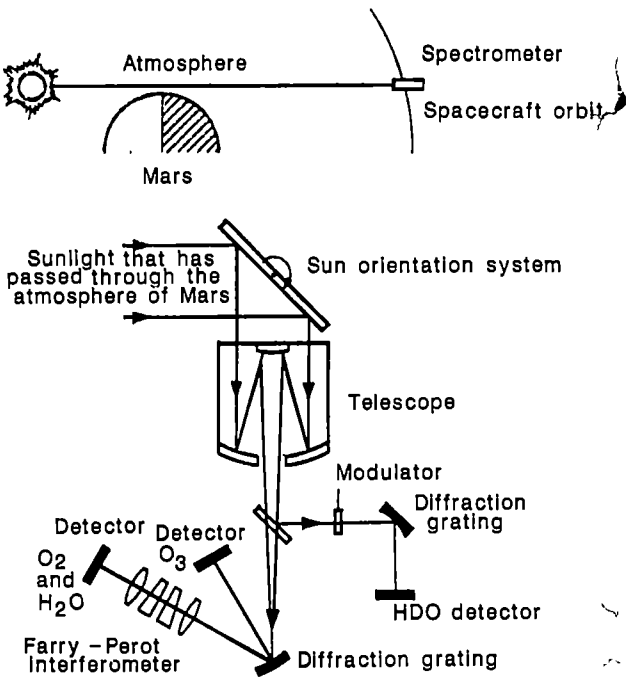

FIG. 1 Schematic diagram of instrument.

The instrument that we used to observe solar occultations in the atmosphere of Mars is shown in Fig. 1. A biaxial pointing device (a microprocessor-controlled flat mirror of elliptical shape, 6×8.5 cm, gimbal mounted, with coarse and fine adjustments forms the image of the Sun in the focal plane of a Cassegrain telescope (diameter 5 cm and equivalent focal length 75 cm). The pointing accuracy achieved in martian orbit was >20 arcsec, and the acquisition time was 4 s.

A diaphragm of 150-μm diameter placed in this focal plane reduces the angular dimension of the Sun to 1 arcmin and it is the spectrum of this spot that is analysed. The vertical resolution is 3 km in circular orbit but can fall to 10 km for observations from a high periapsis eccentric orbit or when the integration time constant is increased to 4 s.

The light admitted through the diaphragm is sent through a beam splitter into three different dispersive systems: a spectrograph using a holographic grating provides a spectrum of 512 elements in the spectral range 215-328 nm. It detects ozone in the Hartley band with a resolution varying from 1.2 nm at 215 nm to 2.4 nm at 328 nm; a Fabry-Perot interferometer placed behind a predispersing grating provides two spectra of 80 elements each, the first has a 0.2 nm spectral range centred at 760 nm (O_2 bands) and the second has a 0.3-nm spectral range centred at 936 nm (H_2O bands). The resolution is 150,000, the finesse is 50 and the spacing is 0.15 cm; a grating spectrograph provides two spectra of 24 elements each, in the ranges 5,290-5,370 cm^{-1} and 2,707-2,740 cm^{-1} for the detection of CO_2, H_2O and D_2O (see ref. 1). The resolution is 10^3.

The detectors of all spectrographs are linear arrays of photodiodes, which detect all the spectral elements simultaneously; the integration time varies from 0.1 to 4 s. The ultraviolet spectra that we report here were obtained using a nominal integration time of 0.1 s, with occasional use of a 0.4-s integration time.

The instrument operated between 8 February and 23 March (the martian equinox occurred on 17 February; 32 occultations were observed during ingress and 1 was observed during egress. The lack of egress observations is because of the unstabilized altitude of the spacecraft during all but one eclipse. The first two occultation measurements were obtained when the space-

craft was in one eccentric orbit (periapsis, 4,270 km; apoapsis, 83,565 km; period, 79.2 h), the third when the spacecraft was in another eccentric orbit (periapsis, 9,800 km; apoapsis, 87,600 km; period, 86.5 h) and all other subsequent observations were made when the spacecraft was in a circular orbit (radius, 9,800 km; period, 8.1 h). (All distances given from the centre of Mars.) The latitude of the intersection of Sun–spacecraft axis with the surface of Mars varied from −11° on 8 February to +18° on 23 March, and the distance between the spacecraft and the limb was ~10^4 km.

Here we present only the results obtained with the ultraviolet spectrograph and the signal obtained in the near-infrared range integrated over the spectral range of 0.2 nm and 03 nm respectively for the 760 nm and 936 nm channels. The instrument had some defects. Stray light added an inverted solar spectrum to the data. (Extra intensity at 320 nm is due to stray light of wavelength 320 nm but the extra intensity at 220 nm is due to stray light with wavelengths in the range 500–400 nm.) Also there was a fast degradation of the optics in the range 260–230 nm after the shutter was opened on 5 February. The effect of stray light on the 220–320 nm range was removed by considering as the signal, the difference between the bottom of a Fraunhofer line and the adjacent maximum. The existence of stray light with a well-defined spectral composition has the favourable consequence of providing information on the occultations in the 320–520 nm range, however, with a poor resolution (10–50 nm depending on the position in the spectrum).

The most conspicuous feature in the data is the time lapse between the occultation curves in the visible (940 and 760 nm) and in the ultraviolet (320–260 nm): in the ultraviolet the extinction of solar light is observed at altitudes from 40 km down, whereas the extinction in the visible starts only around 30 km. We attribute this difference to the existence of solid particles whose dimensions d are on the order of the wavelength $\pi d/\lambda = 1$, that is, $d = 0.1$ μm, much smaller than the 4-μm particles

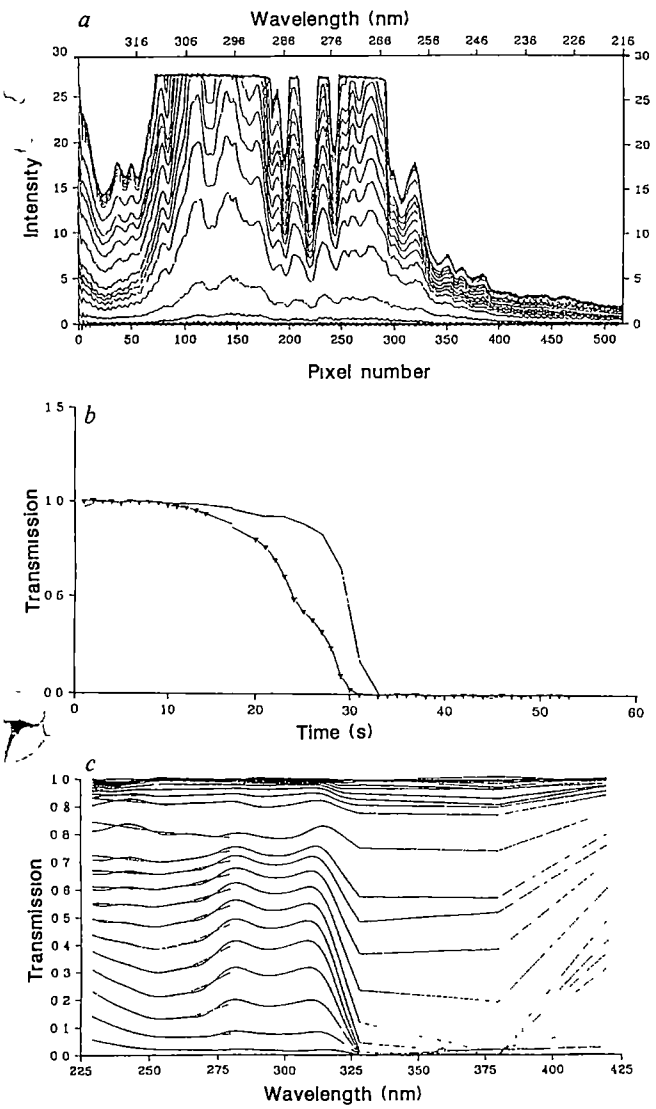

FIG 2 Type I occultation curves obtained on 8 February 1989 (elliptic orbit). *a*, Series of solar spectra obtained during the occultation. Pixel 0 corresponds to $\lambda = 330$ nm, pixel 512 to $\lambda = 220$ nm. Note saturation at the beginning of the occultation. Pseudo absorption feature between pixels 0 and 70 is the result of shape of filter. *b*, Comparison of ultraviolet and visible occultation curves. Solid line is visible data, solid triangles are ultraviolet data. *c*, Extinctions in the range 225–280 nm, 280–310 nm and 310–330 nm are due to ozone absorption, solar-spectrum saturation artefacts and absorption band of unknown origin, respectively; the spectrum in the range 330–425 nm was deduced from stray-light analysis

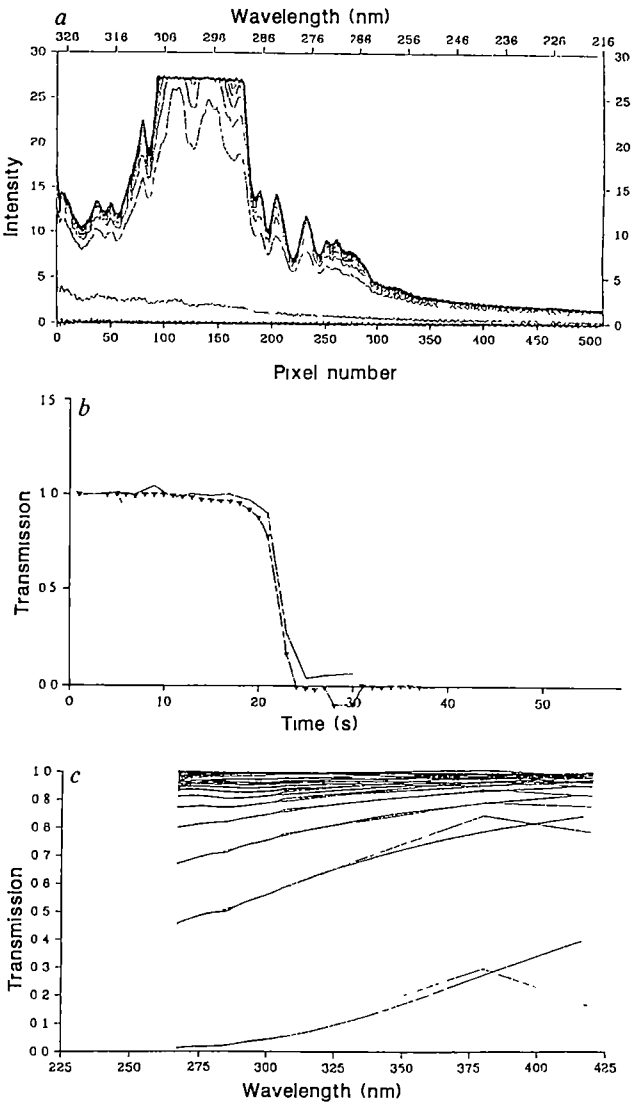

FIG 3 Type II occultation curves (same presentation as Fig. 2 obtained on 16 March 1989 (circular orbit). *a*, Series of spectra obtained during occultation Degradation of coatings by solar light results in loss of sensitivity Compare lowest spectrum on Fig 2*a* and 3*a* between pixels 0 and 150· there is evidence for absorption on Type I but not on Type II *b*, Comparison of UV and visible occultation Solid line is visible data; solid triangles are ultraviolet data. *c*, Series of extinction spectra. Solid lines are λ^{-4} theoretical curves. Dotted lines are experimental curves; note absorption above 400 nm

detected by Viking at lower altitudes. We obtained no data below an altitude of 15–20 km. (The altitude determinations are preliminary and could be in error by ±5 km.)

In the ultraviolet range, the occultation curves are highly variable from orbit to orbit and we identify three types—24 curves of type I, 7 of type II, and 2 of type III. Type I (Fig. 2): the visible absorption starts 3–5 s (in circular orbit) after the ultraviolet absorption with a scale height of 5 km. The major characteristic of type I is the strong absorption in the spectum between 400 and 310 nm, usually below 40 km of altitude. In the majority of cases, the absorption between the altitudes of 50 and 40 km is greater at 280 nm than at 320 nm, but from 40 km downwards, it is greater at 320 than at 280. From 940 nm to 260 nm, the intensity of the absorbed light varies as $\lambda^{-1.5}$ indicating a mixure of Mie and Rayleigh scattering. Type II (Fig 3): the extinction in the visible starts only 1 to 2 s after the ultraviolet. Both ultraviolet and visible transmissions decrease slowly for a short period, then very sharply: their scale height varies during the occultation from 7 to 2.5 km. There is no absorption in the 400–310 nm region. From 400 nm to 250 nm, the intensity of the light varies as $\lambda^{-3.8}$, indicating quasi-Rayleigh scattering. We suspect that the slope and the spectrum of these type II occultations may have been perturbed by a defect in the pointing system, and that the data are reliable only for the top of the atmosphere. Type III: the occultation curve is not monotonic, but shows a strong oscillation at an altitude of ~40 km. This indicates a thin cloud layer at this altitude, which removes the solar light at all wavelengths and perturbs the behaviour of the pointing system. Such horizontal layers have been frequently observed during the Viking mission.

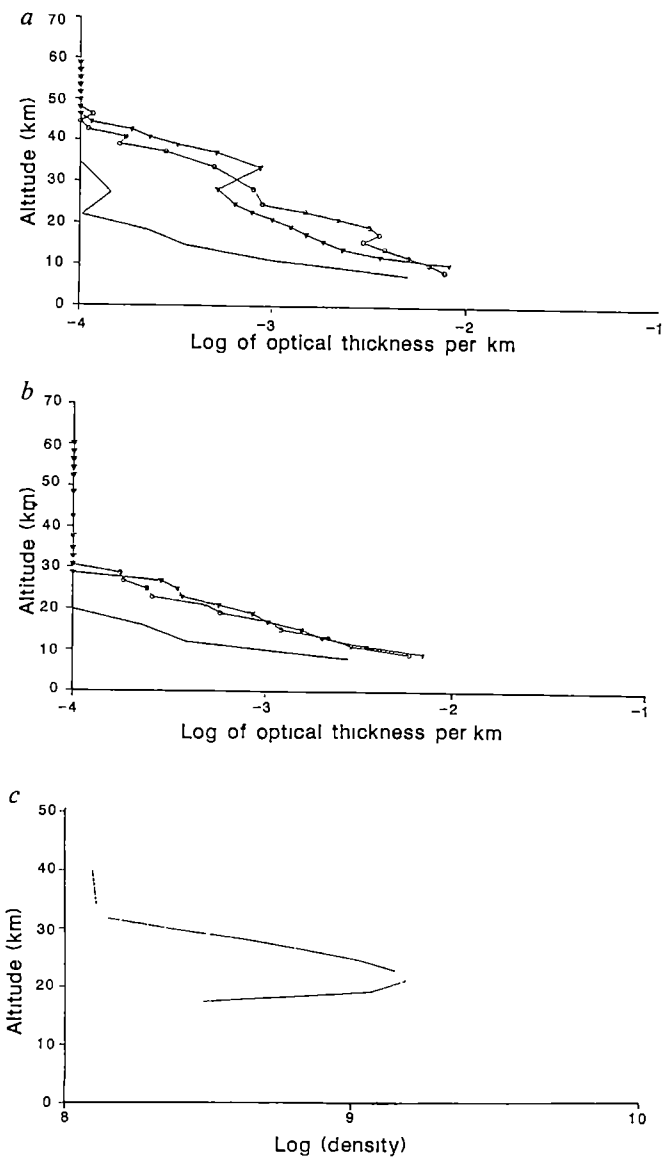

FIG. 4 *a*, Vertical distribution of extinction for type I on 8 February 1989. Open circles are 320-nm data, solid triangles are 280-nm data; solid line is the visible data *b*, Another example of extinction for type I, 21 February 1989 *c*, Vertical distribution of ozone 8 February 1989

Our observations are compatible with the existence of two kinds of particles, that were postulated based on the Mars 5 observations[2]:

Type A particles: Figure 2*c* gives the absorption spectrum characterizing these particles. From 230 to 330 nm, the spectrum is deduced directly from the observed spectrum and from 330 nm to 430 nm, we deduced the spectrum from an analysis of the stray light. In the latter case the resolution is poor but the intensities are reliable. The absorption increases sharply at 310 nm, peaks at ~380 nm and extends to ≥430 nm. The identification of the particles remains uncertain. Silicate dust originating from the soil is an obvious choice. Candidates for the metals in the dust, which are responsible for the ultraviolet absorption band, are Fe^{3+} (refs 3 and 4), TiO_2 (ref. 5), Mn^{2+} (ref. 6).

The particles detected in occultations seem to be different from the particles observed by the Viking lander. The spectra of those particles have a strong minimum in the imaginary part of the index of refraction at 760 nm with values of 0.025 at 760 nm and 0.050 at 936 nm[7], attributed to magnetite. The occultation curves presented here at these two wavelengths are nearly identical and present in nearly all the cases the same intensity for these two wavelengths. Particles of haematite, 0.1-μm dimension[8], might be responsible but the rapid decrease of absorption near 315 nm is not compatible with the presence of Fe^{3+}.

Type B particles: Figure 3*c* gives the extinction spectrum characterizing these particles. Because they possess no strong absorption features, they are not easy to identify. The atmospheric temperature is too high for CO_2 ice to exist, and therefore our prime candidate is H_2O ice. We have evidence for an absorption band starting at 380 nm which could coincide with the inflexion in the variation of the imaginary part of the refractive index of H_2O ice[9].

The optical thickness that results from the particles of either type is of the order of 10^{-4} km^{-1} at the altitude of 30–40 km and 10^{-3} km^{-1} at 20 km (Fig. 4*a*). This corresponds to an optical thickness of 10^{-8} cm^{-1} over a vertical column of 1 cm^2 section, or to a number density of the order of 10^4 particles cm^{-3} for an average radius of 5×10^{-2} μm. A molecule travelling with a thermal velocity will encounter such a particle every few seconds. Even with a small sticking coefficient, the molecules will be adsorbed within a short time, and reactions at the surface can occur that would be forbidden in an all-gaseous phase[10]. It is therefore necessary to modify the aeronomical models of CO_2 stability in the martian atmosphere, developed mainly in 1971 after the first Mariner 9 measurements of O_3 and CO[11,12]). *In situ* heterogeneous chemistry may have a major role in the martian atmosphere.

The occultations were performed in a dry atmosphere and in the equatorial region where even the total ozone density is below the detection threshold of the instruments previously used. Here we obtained ozone profiles during the whole period in which the instrument operated. From the absorption spectrum obtained on 12 February (Fig. 2*c*), we deduced the profile in Fig. 4*b*, assuming Rayleigh scattering by the atmospheric CO_2 (17% at 250 nm) and no other absorber in the spectral range. All the profiles obtained seem similar for type I occultations. Previously, only integrated values of the total column abundance of ozone had been obtained[13–15]. □

WE present solar occultation measurements, taken from Phobos 2, of the H_2O and CO_2 bands at 1.9 μm and of the dust absorption at 1.9 and 3.7 μm. From these, we have calculated vertical profiles of water vapour, dust and atmosphere temperature in the range of 10–70 km. The water-vapour mixing-ratio profile demonstrates oscillations from 10^{-5} to 10^{-3} with a period of 25 km. We explain this behaviour by the condensation and evaporation of water at minima and maxima of the temperature oscillations.

Our instrument was a grating spectrometer with a thermoelectrically cooled array of lead selenide detectors forming 48 pixels. The first-order diffraction covering the spectral range 2,740-2,707 cm^{-1}, was imaged onto 17 pixels and 20 pixels were used for the second-order diffraction, covering the spectral range 5,364-5,292 cm^{-1}. The orders of diffraction were separated by using appropriate filters and by not using 11 pixels in the middle of the array. The calibration data show that the resolving power of the instrument is close to the design specification of $\lambda/\Delta\lambda$ = 1,000. We used the solar pointing system and telescope of the French solar occultation package[1]. Eight successful occultation observations were made at sunset, and one at sunrise, in the equatorial latitudes of Mars. Here we discuss the preliminary results of water vapour and dust measurements obtained from a sunset occultation observed on 13 March 1989. The interpretation of our HDO band (3.7 μm) observations will be given elsewhere.

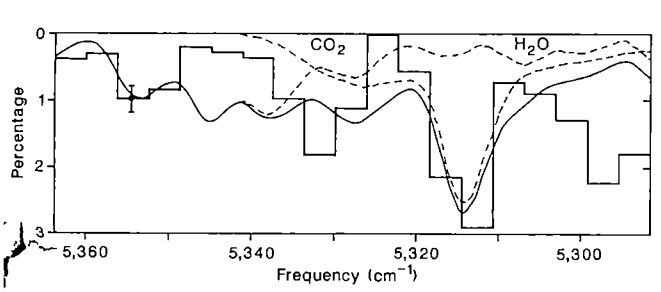

FIG. 1 Spectrum at 1.9 μm measured at 58 km (solid line) with error bars. Calculated absorption spectra of CO_2 and H_2O for the model atmosphere with $H_2O/CO_2 = 3 \times 10^{-4}$ are shown by dashed lines and their sum by a thin line.

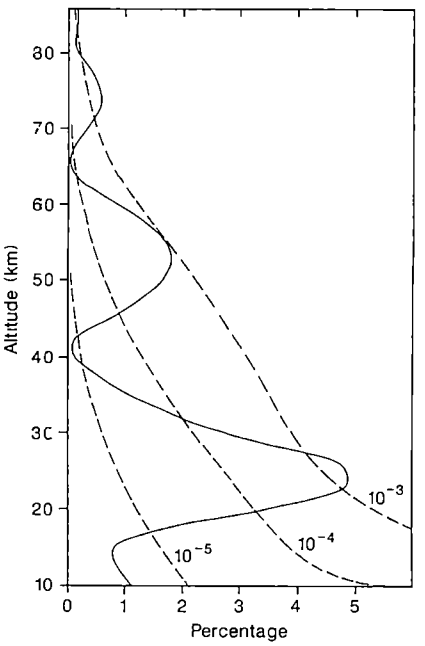

FIG 2 Altitude profiles of the measured (solid line) and calculated (dashed line) water vapour absorption at 5,353 cm^{-1}. Calculations were for three H_2O mixing ratios, 10^{-5}, 10^{-4} and 10^{-3}.

One of the second-order spectra measured at an altitude of 58 km is shown in Fig. 1. Most of the features of this spectrum are typical of our spectra. Continuous absorption by aerosol is present in all spectra and constitutes ~20% in the spectrum in Fig. 1. The gaseous absorption readily identified is the CO_2 band at 5,314 cm^{-1}. The first four pixels on the left-hand side of the spectrum follow the spectrum of the H_2O band and we used these to evaluate the water-vapour mixing ratio. The calculated spectrum does not, however, reproduce the measured one well. The most important differences are the absence of the H_2O absorption at 5,340-5,350 cm^{-1} and the presence of features at 5,332 and 5,298 cm^{-1} in the observed spectra (these differences exceed the error bars, ±0.25%). The reason is probably the very low intensity of the gas absorptions (~1%) which is much less than the aerosol absorption. Small spectral variations of the latter may therefore significantly influence the measured spectrum.

We evaluated the intensity of the H_2O band at 5,353 cm^{-1} by comparing the signals for two pixels inside and two outside the band (Fig. 2). Three altitude profiles for this band that we calculated using three values of the water-vapour mixing ratio (10^{-5}, 10^{-4} and 10^{-3}) are also shown. At first glance the variation of the mixing ratio by two orders of magnitude is unexpected. Previous studies made by Viking spacecraft[2] showed that the water vapour is well mixed with the dust up to 10 km. This assumes a constant mixing ratio in this altitude range, which is below our range. Extrapolating the Viking data, one might suggest that the water-vapour mixing ratio on Mars should be

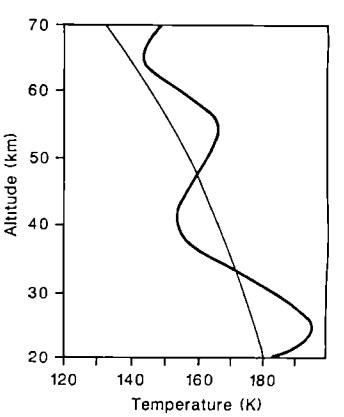

FIG 3 Temperature profile of the mid-altitude atmosphere of Mars deduced from the data of Fig 3. Thin line is the model profile[3].

constant with the mean value of $\sim 2 \times 10^{-4}$ up to 15–20 km and then decrease by one and two orders of magnitude by altitudes of 40 and 60 km respectively, following the saturated vapour-pressure curve. We suggest that the behaviour of the H_2O absorption is the result of the very strong temperature-dependence of the saturated water vapour pressure. The observed oscillations in the amount of water vapour correspond to the temperature oscillations with an amplitude of 10–15 K. Evaporation of ice aerosol grains occurs at temperature maxima and condensation of water vapour and formation of grains occurs at minima. To prevent sedimentation of the grains the atmospheric mixing must be strong, but to evaluate its lower limit the size distribution of ice grains must be known.

In Fig. 3 we compare the altitude profile of the atmospheric temperature deduced from the data in Fig. 2 with the model profile[3] given by the relationship $T(z) = 185 - 0.05z - 0.01z^2$. The length and the amplitude of the temperature oscillations

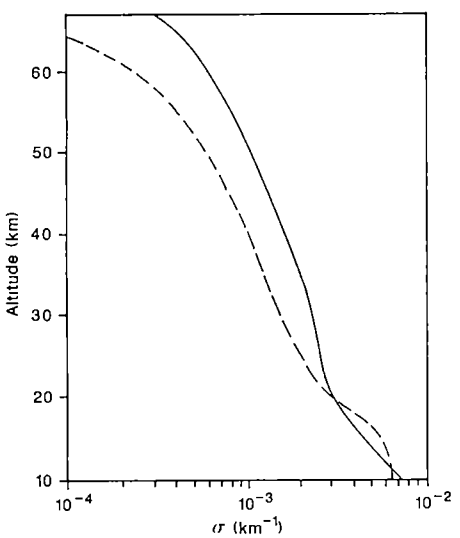

FIG 4 Aerosol volume extinction coefficients at 1.9 and 3.7 μm (solid and dashed lines, respectively).

(25 km and 15 K) are close to those observed by the Viking entry probes[4]. These oscillations may be caused by internal-gravity waves (tidal waves). The sensitivity of water vapour pressure to the temperature of the atmosphere makes occultation measurements of water vapour bands a powerful tool in the study of these waves. But we do not see the increase of the amplitude of the wave with altitude that we expect for internal-gravity waves in the absence of dissipation.

Aerosol extinction can be measured easily by a solar occultation technique. The range of measurements covers from several per cent of absorption to ~99% absorption in the atmosphere. Figure 4 shows the Abel inversion of these measurements. At 60 km, the measured volume extinction coefficient at 1.9 μm is three times larger than that at 3.7 μm and becomes smaller than that at 3.7 μm between 20 and 10 km. Preliminary analysis of this behaviour in terms of Mie theory for two kinds of aerosol, water-ice particles and particles formed of a mixture of basalt and limonite (2.5%) (ref. 5), gives almost the same results: the effective mean radius of particles, r, is ~1 μm near 60 km, increasing to 3 μm at 10–20 km. A combination of these results with the ultraviolet and visible data[1] will allow further conclusions to be made about the aerosol composition and size distribution. Between 10 and 20 km the aerosol scale height measured at 1.9 μm is 11.5 km, (close to the atmospheric scale height). The equal scale heights presume well-mixed aerosol below 20 km. Extrapolating this mixing ratio to the surface of the planet we obtain an optical depth of aerosol equal to 0.3 which is in accord with the Mars 5 measurements[6] and Viking landers[7]. Above 20 km the aerosol mixing ratio seems larger than in the lower atmosphere. The problem should be considered, however, with the mean particle radius r taken into account. The sedimentation flux is roughly proportional to r^5, whereas the volume extinction coefficient varies as r^2. After this correction the ratio of the sedimentation flux to the atmospheric density is almost constant between 10 and 60 km. This may be important for theoretical study of the dust distribution in the martian atmosphere. □

BASED on the examples of the Earth and Moon, we expect that Mars has or once had an intrinsic planetary magnetic field. The Earth has a large magnetic moment, 8×10^{15} T m^3, and the Moon's remanent magnetism in its surface rocks indicates that it once had a magnetic field[1]. The radius of Mars (3,390 km) is intermediate between that of the Earth (6,371 km) and of the Moon (1,738 km). Its smaller size has led to a more rapid thermal evolution than Earth's but we do not know whether Mars still generates a magnetic field or has passed into a Moon-like state. The Mariner 4, and Mars 2, 3 and 5 missions have placed upper limits on the martian magnetic moment[2,3] in the range of $1\text{–}5 \times 10^{12}$ T m^3 corresponding to an equatorial surface field of 25–125 nT. We have measured magnetic fields with high temporal resolution in the tail and down to an 850-km altitude. During four successive highly elliptical orbits we identified the position of the bow shock as well as of a transition layer, the 'planetopause'. Subsequent circular orbits at 6,000-km altitude provided the first high-resolution data in the planetary tail and indicate that the interplanetary magnetic field mainly controls the magnetic tail. We also detected magnetic turbulence when the spacecraft crossed the orbit of the moon Phobos, indicating the possible existence of a torus near the orbit of this moon.

Phobos 2 carried two triaxial flux-gate magnetometers: the experiment MAGMA (magnetic fields near Mars) and the

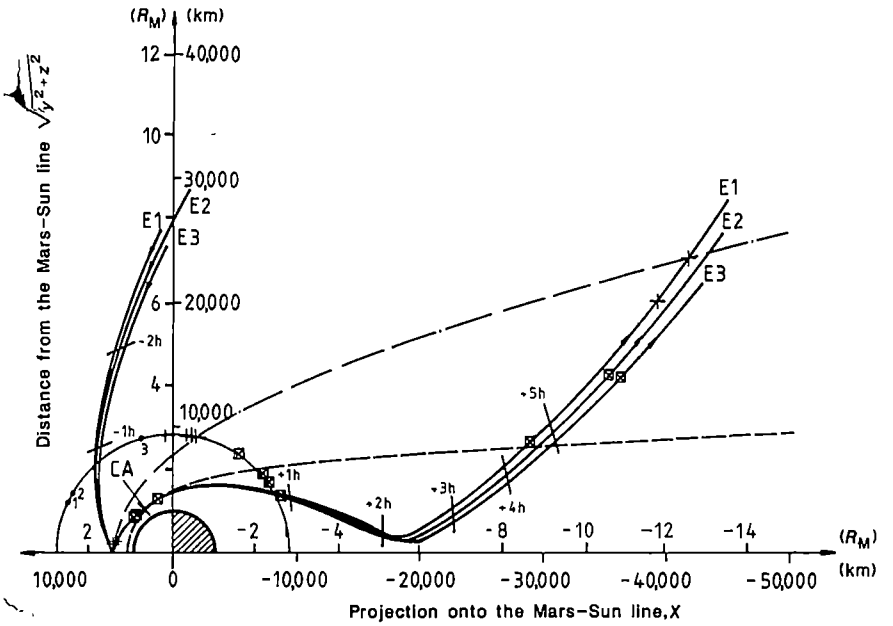

FIG. 1 Main boundaries and events observed by the FGMM and MAGMA experiments during the first three low-altitude elliptical orbits (E1, E2 and E3) and during circular orbits (outer semi-circle) around Mars. Tick marks indicate hours relative to the closest approach (CA). Squares denote inbound and outbound crossings of the planetopause, crosses the positions where the magnetometers observed the bow shock.

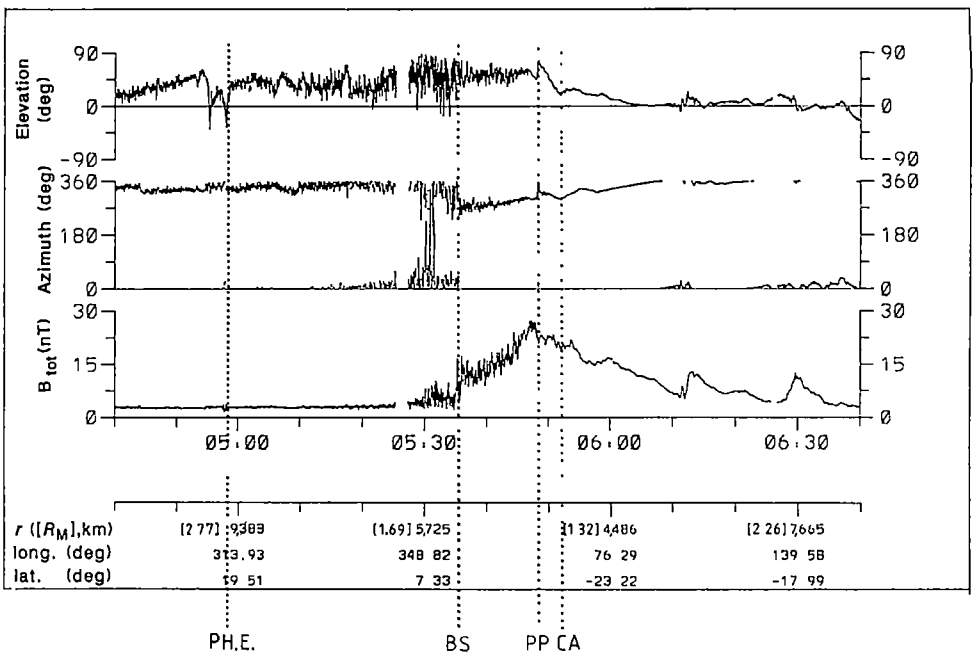

FIG. 2 Magnitude and orientation of the magnetic field vectors (FGMM experiment) measured during elliptical orbit 3 near closest approach (altitude = 850 km, $r = 1.25\ R_M$). Temporal resolution is 2.5 s. The magnetic field is presented in the areocentric solar-ecliptic coordinate system, where the elevation is measured with respect to the orbital plane of Mars (x, y) and the azimuth with respect to the Mars–Sun line (azimuth is 0 towards the sun). The lower panel shows longitude and latitude and the distance of the spacecraft from the centre of Mars r. BS denotes the inbound bow shock, PP the inbound planetopause and CA the closest approach. The disturbance observed at 4:48 UT (label PH.E.) is the so-called Phobos event.

experiment FGMM (flux-gate magnetometer Mars). Both instruments had a range of ±100 nT, a resolution of 0.05 nT and returned data at the rate of one vector every 1.5, 2.5, 45 or 600 s depending on the telemetry mode of the spacecraft. The MAGMA magnetometer was mounted on the top of a 3.5-m boom and the FGMM magnetometer was mounted on the same boom, 1 m closer in. The dual-magnetometer configuration and the pre-launch magnetic mapping of the spacecraft allowed us to estimate the spacecraft field at the location of the MAGMA sensor (<1 nT). The total offset (sum of the internal offset and the spacecraft field) was calculated from the magnetic field data from the spinning and rolling sessions using statistical methods[4]. More details about the instruments and the in-flight performance can be found elsewhere[5].

Figure 1 shows the first three elliptical orbits of Phobos 2 and the general features of the solar-wind interaction with Mars in cylindrical coordinates. Initially, Phobos 2 entered a highly elliptical orbit with a 77-h period and a closest approach of $r = 1.2507\ R_M$ (measured in units of Mars radii from the centre of the planet). The martian tail was crossed 2.4 h after closest approach at a radial distance of ~5.6 R_M. In Fig. 1 the distance of the spacecraft from the Mars–Sun line is plotted against the distance along it; the orbit is therefore folded over on itself. After four low-altitude orbits of this type the spacecraft performed one elliptical orbit with a periapsis at 2.83 R_M and later transferred into a circular orbit at 2.83 R_M, 300 km above the orbit of Phobos, circling the planet every 8 h. Until the end of the mission on 27 March 1989 we obtained magnetic field data during 80 circular orbits—50 orbits with a resolution of 45 s and 30 orbits with a resolution of 600 s. Near the pericentre of the four low-altitude elliptical orbits, the magnetometers transmitted 1 vector every 1.5 s (MAGMA) and 2.5 s (FGMM). Figure 2 shows magnetic field measurements obtained on the third elliptical orbit near the pericentre. We observed a typical undisturbed interplanetary magnetic field (IMF) with a magnitude B_{tot} of ~3 nT and with fluctuations of the field direction (azimuth, elevation) until 5:30 UT when the field magnitude started to become turbulent. Five minutes later when Phobos 2 crossed the bow shock we observed a jump in the field magnitude (to a maximum of 28 nT) and a decrease in the fluctuations of the

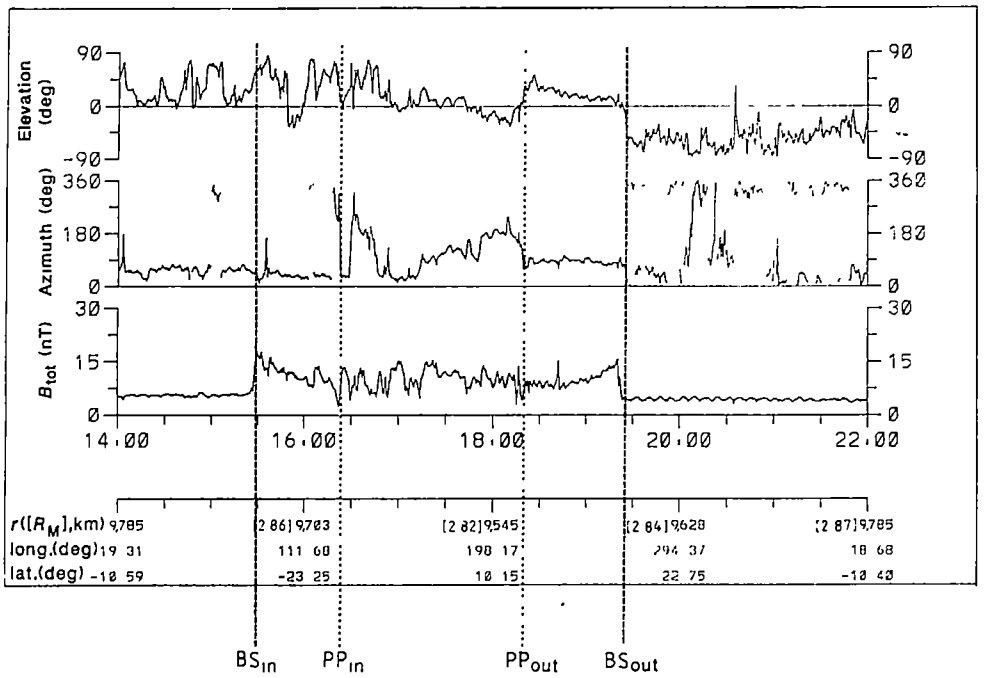

FIG. 3 Magnitude and orientation of the magnetic field (MAGMA experiment) during one of the circular orbits. Temporal resolution is 45 s. BS_{in}, PP_{in}, PP_{out} and BS_{out} are inbound and outbound bow shock and planetopause, respectively.

azimuth and elevation. Then the spacecraft passed a boundary, which we call the planetopause, that is characterized by a rotation and by a drop in turbulence of the magnetic field. At the planetopause the solar-wind protons also disappeared[6]. After this boundary, the field remained quiet and the magnitude decreased gradually. We call the disturbance at 4:48 UT near the orbit of the moon Phobos, the Phobos event. We observed the same boundaries and events during other elliptical orbits; their time and position (areocentric distance, longitude and latitude) are summarized in Table 1. Figure 3 shows the magnetic fields we observed during one of the circular orbits. The bow shock, inbound and outbound is characterized by a jump of the total magnetic field. The reversal of B_x at 17:20 UT is typical for the crossing of the martian tail and the polarity of the reversal depends mainly on the orientation of the perpendicular, undisturbed IMF component observed before the bow shock. The inbound and outbound crossings of the planetopause are characterized by the disappearance and reappearance respectively, of the solar-wind protons[6]. In some cases the magnetic field magnitude increased or decreased during the inbound or outbound crossings, respectively.

As illustrated in Fig. 1 the orbits of Phobos 2 were better suited for investigating the solar-wind interaction with Mars than those of previous spacecraft[7]. The elliptical orbits came almost twice as close as the orbits of previous spacecraft and provided data directly behind the planet. The location of the bow shock has been studied extensively on previous missions. The analysis[7] had obtained subsolar (nose) radii of 1.36–1.85 R_M and terminator radii of 2.36–3.07 R_M. Initial Phobos 2 observations show that the bow shock is located with a nose radius of ~1.45 R_M and a terminator radius of about 2.40 R_M We calculated these values using a gas-dynamic model[8] with the shape of the obstacle from Fig. 1 (dashed line), a Mach number of 10 and a ratio of specific heats of 5/3. We fitted the obstacle to

Times are in UT and distances are measured from the centre of Mars. E1, E2 and E3 denote the first three of five elliptical orbits; K1 and K2 are examples of the about 80 circular orbits from which magnetic field data are available. The boundaries and events are determined with an accuracy of ~1 min.

the observed locations of the planetopause, where the solar-wind protons are disappearing. The term planetopause was chosen by analogy with the cometary cometopause where the solar-wind ions also disappear[9]. The nose of the fitted planetopause is 0.1180 R_M (400 km) above the martian surface. As the calculated bow shock (dash-dotted line in Fig. 1) fits the observed bow-shock crossings well (crosses in Fig. 1), we conclude that the observed planetopause is close to the obstacle that deflects the solar-wind flow around Mars thus forming the bow shock.

The wake of a magnetized planet is a region of magnetic fields with a large sunward or antisunward component. A current sheet separates the regions of opposite magnetic polarity or tail lobes. The polarity is controlled only by the intrinsic magnetic moment of the planet. By contrast an induced magnetotail has lobes with polarities controlled by the interplanetary magnetic field. We therefore checked the influence of the interplanetary field on the polarity of the lobes during the circular orbits and found several cases similar to Venus[10] where a reversal of the perpendicular IMF component caused a reversal of the tail lobes. This indicates the existence of an ionospheric type of interaction with the solar wind at distances $>2.8\ R_M$.

The analysis of the magnetic field data that we have done so far gives no conclusive evidence for an intrinsic magnetic field. A future analysis of the Phobos 2 magnetic field and plasma data near the closest approach ($r = 1.25\ R_M$) together with computer simulations of the interaction of Mars with the solar wind will improve our knowledge about the parameters of the intrinsic field.

Although we have no evidence for any direct effect of the moon Phobos on the solar wind we have observed an occasional disturbance in the magnetic field as the spacecraft crossed the moon's orbit (labels 1, 2 and 3 in Fig. 1 denote the position of the moon). A possible explanation is that the solar wind interacts with a torus of dust generated by meteorite bombardment of the surface of Phobos[11]. The disturbance is, however, not unlike disturbances caused by particles backstreaming from planetary bow shocks so these observations need further investigation. □

HERE we report preliminary results from electic field measurements in the environment of Mars using the plasma-wave system on board the Soviet spacecraft Phobos 2. It also includes a Langmuir probe which measured plasma densities. Electron-plasma oscillations observed upstream of the bow shock correspond to a solar-wind density of 2 cm^{-3}. The shock-foot boundary was crossed up to three times on each orbit. The shock ramp was detected at altitudes between 0.45 and 0.75 Mars radii (R_M) above the planetary surface. The density increased by about a factor of two at the ramp. The shock position, although variable, seemed to be consistent with previous measurements. The downstream magnetosheath contained broadband electric-field noise below the plasma frequency. The boundary of the obstacle, or planetopause, was crossed at altitudes of the order of 0.28 R_M; the cold plasma density was highly variable within the planetopause and reached the unexpected value of 700 cm^{-3} on the third orbit, at 0.25 R_M altitude. Bursts of waves with frequencies below the electron cyclotron frequency, possibly in the whistler mode, occur within the planetopause.

The scientific objectives of the plasma wave system (PWS) on board Phobos 2 are: (1) to analyse the frequency spectrum of the electromagnetic and electrostatic waves in the environment of Mars; (2) to detect the boundaries associated with the interaction of the solar wind with the ionosphere and magnetosphere of the planet; (3) to measure the plasma density distribution in the martian ionosphere; (4) to search for the possible existence of plasma density enhancement and wave activity resulting from the interaction between the solar wind and any material possibly outgassed from the Martian satellite Phobos; (5) to measure the spacecraft potential. The PWS instrument includes two sensors: a dipole antenna made of two 10-cm diameter spheres separated by 1.45 m and a Langmuir probe with a collecting area of 6 cm^2. Further technical information about the instrument is given elsewhere[1]. Electrostatic plasma waves were detected sporadically in the upstream solar wind on all four passes within an areocentric distance of 4.8 R_M. Because the frequency responses of adjacent filters in the PWS crossover at attenuations of only 3 dB, an intense narrow-band signal is detectable in several frequency channels. By assuming that the plasma frequency corresponded to the highest intensity channel, however, we deduced electron-plasma frequencies and densities consistent with those expected. The observations made during the first approach to the planet (Fig. 1, panel 1) yield a plasma frequency and electron density of 13 kHz and 2 cm^{-3}, respectively.

Phobos 2 crossed the outer boundary of the shock foot at 18:08, 18:12, and 18:14 UT on the first orbit (Fig. 1, panel 2). This boundary is the envelope of turnaround distances of solar-wind ions that are specularly reflected at, and are subsequently returned to, the shock ramp after completing a partial gyration in the upstream magnetic field[2]. The foot boundary was identified by a change in character of both the wave and Langmuir-probe data. As at Earth and Jupiter[3], the plasma waves in the shock foot of Mars appear as broad-band noise extending from below the lower hybrid frequency to the electron-plasma frequency. The Langmuir probe detected a slight gradual increase in electron density throughout the shock foot.

The shock ramp, which separates the shock foot upstream from the magnetosheath downstream, can be more easily identified from changes in overall Langmuir-probe response than they can from the broadband plasma wave shown in Fig. 1. More detailed inspection of the plasma-wave spectra indicates that the electron density jumped by about a factor of two at the shock ramp. A more precise evaluation of this density jump will require further analysis. The shock foot and magnetosheath are both regions of enhanced plasma wave activity with similar spectra, except that electron-plasma oscillations were more apparent upstream.

We have chosen the neutral name 'planetopause' (instead of magnetopause or ionopause) for the boundary separating the shocked magnetosheath from the planetary obstacle. Planetopause crossings were identifiable in both wave and Langmuir-probe data. Inbound crossings were preceded by significant modifications in the wave spectra, illustrated by the fourth panel

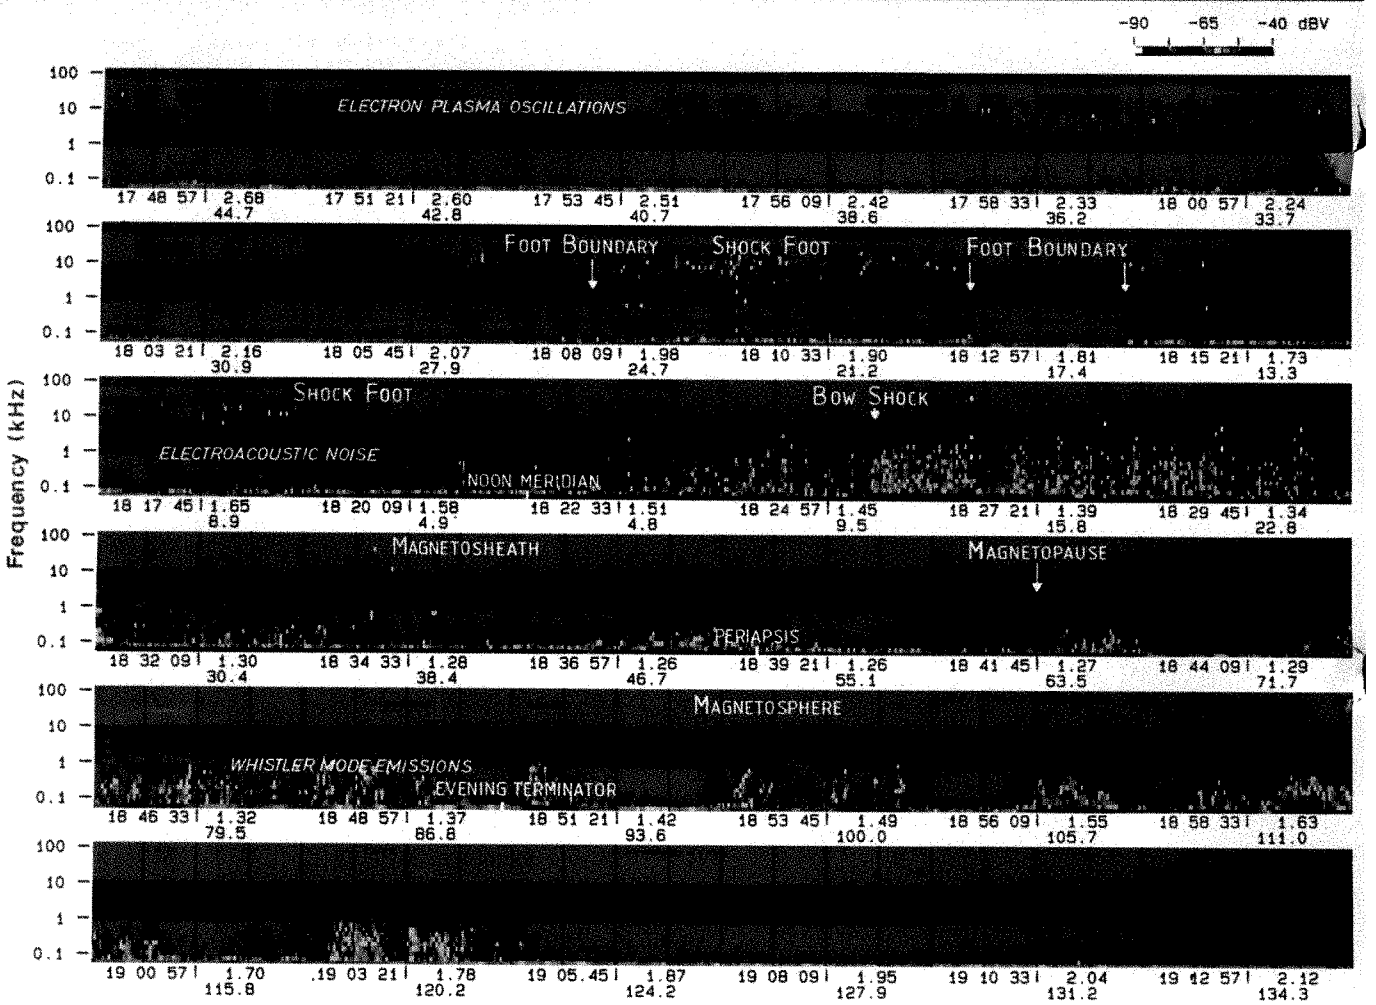

FIG. 1 Summary of a continuous-wave data sequence recorded on 1 February 1989 with the dipole antenna of PWS during the first orbit of Mars by Phobos 2. This spectrogram is a raster made of the 25 signals delivered by the filter bank; the r.m.s. value of the voltage measured with each filter is evaluated with the colour scale at the top right (−40 dBV = 10 mV r.m.s.). The central frequency of the bandwidth covered by each channel is marked on the left axis. Time (UT) is given along the horizontal axis to the left of each tick; the areocentric distance of the spacecraft (R_M) and the solar zenith angle (deg) are written to the right of each tick, top and bottom respectively.

of Fig. 1. The broad-band, presumably electrostatic, noise disappeared before Phobos 2 left the magnetosheath. The Langmuir-probe data changed character after every planetopause crossing; the temporal profiles were smoother, and the densities were higher inside the planetopause. The density just inside the planetopause varied from orbit to orbit.

The locations of the shock-foot boundary (open circles), shock ramp (crosses) and planetopause (triangles) observed in the sunward hemisphere during each of the four orbits are shown in Fig. 2. With one exception, the ramp crossings are consistent with a model summarizing earlier measurements of the bow shock[4] of Mars; we do not know whether the distinction between foot and ramp was drawn in previous data. One ramp crossing occurred somewhat further from the planet than all others detected thus far, and so did its shock-foot boundary. The thickness of the shock foot and magnetosheath were comparable, several tenths of R_M, confirming the prediction[5] that the foot is a prominent feature of the interactions of the martian environment with the solar wind.

The plasma density was different at each planetopause crossing and was highly variable inside the planetopause. Phobos 2 encountered regions of enhanced density, typically 100 km in extent along the orbit, in which plasma wave activity was not observed. Waves occurred primarily in discrete bursts of 0.5–2 min duration and 100–400 km extent. The signals in the burst between 19:02:30 and 19:04:00 UT (Fig. 1, panel 6) had frequencies <1 kHz, the electron cyclotron frequency in a 36-nT magnetic field. This suggests, but in the absence of wave magnetic-field data does not prove, that the bursts are in the whistler mode.

Phobos 2 measured the highest plasma density, 700 cm^{-3}, near periapsis on the third orbit (Fig. 3); at that time the electron temperature was ~1 eV. Assuming thermal equilibrium, the inferred plasma pressure was that developed by a 25-nT magnetic field, comparable with typical values of the solar-wind dynamical pressure; this peak density occurred 7 min after planetopause crossing and was about twice that observed at this boundary. The peak density on the third orbit was a factor of two or more larger than those encountered on the other orbits, indicating that the plasma density in the dayside environment of Mars varies from day to day. The third-orbit periapsis density is unusually large but is not the result of any instrumental effect or spacecraft interference. The retarding-potential analysers on board the Viking landers[6] measured comparable densities, but at much lower altitudes (300–350 km) than those of the Phobos 2 orbit, whose periapsis altitude was 860 km.

Correlative studies that combine magnetic field, plasma, and energetic-particle data are needed to understand the role played by thermal plasma in the Mars/solar-wind interaction, to determine whether the planetopause is an ionopause, a magnetopause

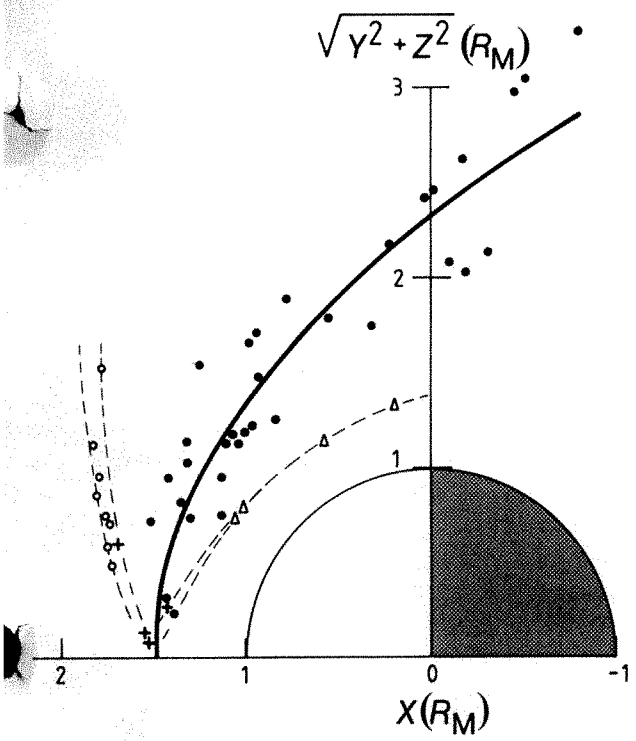

FIG. 2 Locations of the martian shock-foot boundary, shock ramp and planetopause observed with Phobos 2 (open circles, crosses and triangles, respectively, between the envelopes, dashed lines, of the four orbits). The average location of (presumably) the shock ramp (thick line) based on Mars 2, 3 and 5 and Viking 1 observations (full circles) is shown for comparison in aberrated coordinates[4].

or a mixture, and to estimate the convection rate inside the martian magnetosphere[7].

Plasma density and wave-activity enhancements have also been observed in the solar wind when Phobos 2 was at an areocentric distance of 2.77 R_M, which corresponds precisely to the orbital radius of one of the two natural satellites of Mars,

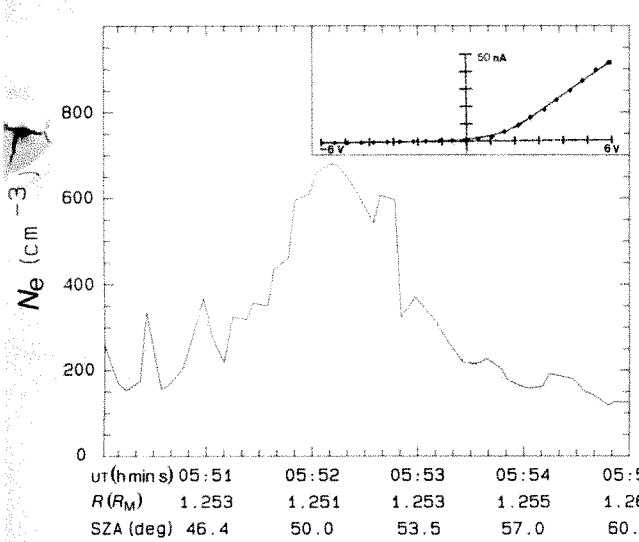

FIG. 3 Electron density profile recorded on 8 February 1989 when Phobos 2 was crossing the periapsis of the third orbit around Mars. Universal time (UT), areocentric distance and solar zenith angle (SZA) are given along the horizontal axis. The inset in the upper-right corner shows a typical current response of the Langmuir probe recorded at 05:52 UT when the bias voltage is swept between −6 V and +6 V with respect to the spacecraft structure; experimental points are represented by crosses; the continuous curve is a theoretical fit to the measurements from which the plasma parameters are derived.

its namesake. Further findings may be expected, because these data represent only a small fraction of the information that was transmitted by Phobos 2 during its two-month operation in the martian environment. □

BEFORE the Phobos mission, the magnetosphere of Mars was relatively unexplored. Basically all data on the charged-particle environment of Mars had come from the Soviet Mars missions (Mars 2, 3, 4 and 5). Here we report the results of an ion-composition experiment on board the Soviet Phobos 2 spacecraft which allowed us to determine the loss of plasma from the ionosphere of Mars. Because Mars has a very small intrinsic magnetic field, the ion outflow had been expected to be similar to that of Venus. Surprisingly, there were many similarities between the ionospheric outflow from Mars and the Earth. The ion loss from Mars results from both ion pick-up that results from mass-loading of the solar wind in the Martian boundary layer and ionospheric O^+ beams of energies up to several keV, possibly from upward acceleration processes similar to those observed above the Earth's auroral oval. A preliminary estimate of the ionospheric outflow from Mars indicates that the planet is losing oxygen at a rate of $\sim 3\times10^{25}$ ions s^{-1}. This corresponds to an evacuation of its present total atmospheric oxygen content (contained in CO_2 and O_2) in less than 100 million years.

Previous missions to Mars have shown (see, for example, ref. 1) that the interaction with the solar wind forms both a bow shock and a magnetopause. There is[2] a smooth transition from the shocked solar-wind plasma to the hot plasma cushion above the ionosphere, which closely resembles the solar-wind interaction with Venus, a planet without an intrinsic magnetic field. A boundary layer inside the magnetosheath with ion fluxes of lower energies than in the magnetosheath has also been observed[2], possibly indicating an ionospheric origin of these ions.

The contribution of the solar-wind interaction to the dehydration of Mars has been discussed[2,3]. The lack of a strong intrinsic magnetic field on Mars (and on Venus) may have had a major role in the loss of atmosphere (and hydrosphere) on Mars by the direct exposure of the upper ionosphere to the solar wind.

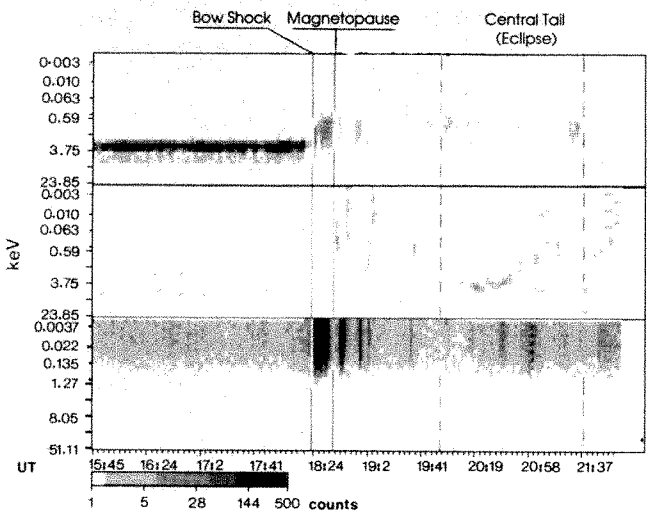

FIG. 1 Energy–time spectrogram of H^+, O^+ and electrons (top, middle and bottom, respectively) flowing away from the Sun. These data were taken during the first orbit of the Phobos 2 spacecraft around Mars, 1–2 February 1989.

The plasma escape from Mars in the tail boundary layer has been calculated[2] to be $\sim 10^{24}$ s^{-1}, corresponding to about 10 g s^{-1} of oxygen. This is, however, too low to explain the dehydration of Mars.

The ASPERA (automatic space plasma experiment with a rotating analyser) ion-composition experiment on board Phobos 2 has made it possible to determine more accurately the ion outflow from the upper ionosphere of Mars. As expected, the ion escape is consistent with the cold-plasma composition in the topside ionosphere inferred[4] from the US Viking 1 and 2 spacecraft, that is, oxygen ions dominate. Moreover, the ASPERA data from the first four Phobos 2 orbits around Mars indicate that the ionospheric loss rate in the martian magnetotail is high enough to explain the dehydration of Mars over its lifetime.

The instrument ASPERA is a plasma-composition experiment that uses a scanner platform to provide nearly complete (that is, three-dimensional) coverage of the unit sphere of the three-axis-stabilized spacecraft. The ASPERA measures the composition, energy and angular distribution of ions of charge e with energies 0.5 eV e^{-1} - 24 keV e^{-1} and electrons with energies 1 eV - 50 keV. The plasma analyser comprises two spectrometer systems with a 360° field of view lying in a plane perpendicular to the plane of rotation (±90°). The 360° field of view is divided into ten sectors for ions and six sectors for electrons, all sectors containing individual sensor elements. The unit sphere can be covered by a 180° turn of the scanner platform.

Figure 1 shows energy–time spectrogram plots for electrons and H^+ and O^+ ions observed during the first two orbits around Mars. The panels correspond to data (~ 4-min running means, ~ 50-ms sampling time) sampled in the sunward sectors of the ASPERA. The important boundary crossings (such as the bow shock and magnetopause) are marked by vertical bars in the panel. The central tail (eclipse) is contained in the region of dashed lines.

In the first orbit the bow shock was crossed near the subsolar point at an altitude of ~ 1,550 km, and the magnetopause was crossed near the location of the pericentre (~ 860 km) in the dusk sector of Mars. We note from Fig. 1 that the most persistent feature inside the magnetospheric cavity of Mars is the dominance of ionospheric ions (O^+). Near the planet (at ~ 18:30 - 19:00 UT) the outflow of 'cold' ions in the few eV range dominates, whereas the central tail is characterized by accelerated cold beams up to several keV. The existence of accelerated cold beams in the central martian tail was quite unexpected and is one of the remarkable similarities between the martian and terrestrial magnetosphere.

Figure 2 displays the number density and flow velocity (v_x = flow velocity away from the Sun) for H^+ ions and the number density for O^+ and molecular ions during the second orbit. The mass resolution is not sufficient to separately resolve the molecular ion species anticipated in this mass range (such as N_2^+, O_2^+ CO^+ and CO_2^+). It is clear from Fig. 2 that the contribution of molecular ion species in the ionospheric ion escape is indeed significant. At times the molecular ion escape even dominates over the atomic oxygen escape. This implies a considerably higher outflow of molecular ions than that found near the Earth. Figure 2 illustrates the main characteristics of an encounter with the martian magnetosphere—strongly reduced H^+ ion densities and flow velocities and a correspondingly large increase of energized ionospheric-ion densities. The density of O^+ ions reaches up to 6 cm^{-3} even in the distant tail of the martian magnetosphere.

Figure 3 shows a composite diagram of the total outflow (in ions cm^{-2} s^{-1}) from Mars of O^+ ions along the spacecraft trajectory of the first and second orbits. The O^+ flux in the martian tail generally exceeds 10^6 ions cm^{-2} s^{-1}. The average O^+ flux during the four first orbits corresponds to $\sim 2 \times 10^6$ ions cm^{-2} s^{-1} in the distant ($x \sim 10 R_M$) tail with an average width of $\sim 8 R_M$. The O^+ outflow in the central tail was very variable but on the average of similar flux intensity as that in the tail boundary.

Figure 4 summarizes the ionospheric outflow observed during the first four orbits. The diagram illustrates that the escape of ionospheric plasma is predominantly found in the tail boundary of Mars. Cooler and denser plasma flows out in narrow structures

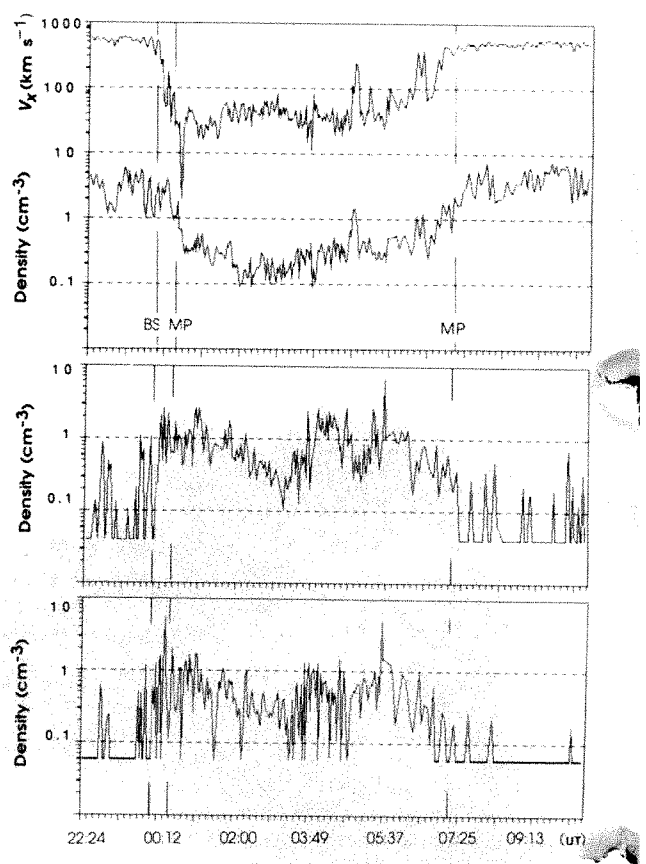

FIG. 2 Moment parameters for O^+ and H^+ ions during the second Phobos 2 orbit around Mars (4–5 February 1989). The top panel gives the flow velocity and the number density of H^+ ions. The middle and lower depict the number density of O^+ and molecular ions (O_2^+, CO_2^+, CO^+), respectively. The inbound bow shock (BS) and magnetopause (MP), and the outbound magnetopause crossings are marked by vertical lines.

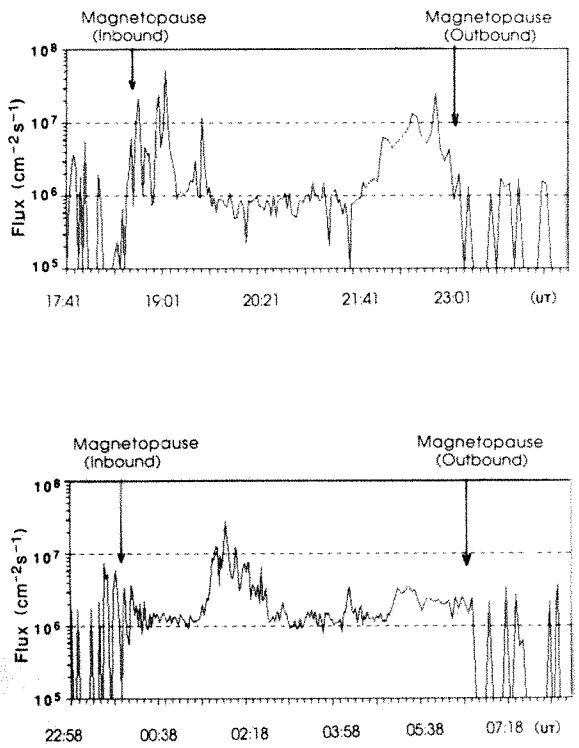

FIG. 3 Composite diagram of the outflow ($n\,v_x$) of ionospheric O^+ ions from Mars during orbits 1 (top) and 2 (bottom).

into predominantly the boundary layer and, subsequently, by the mass-loading process, picks up the boundary-layer flow speed away from the Sun. The central tail region is characterized by a highly variable outflow of O^+ ions which are subject to acceleration processes similar to those found in the terrestrial magnetosphere ('auroral' ion beams).

The rate of ionospheric-ion outflow is indeed very high with fluxes similar to, or exceeding those found in the Earth's geotail. Although the dominant ion constituent of the outflow is oxygen there are strong reasons to believe that the hydrogen-ion escape may be equally significant along the flanks. The hydrogen-ion escape is, however, difficult to distinguish from intruding solar-wind protons.

The atmosphere of Mars, with an atmospheric pressure at ground level of the order of a few millibars, is much thinner and drier than that of the Earth. Furthermore, the lower atmosphere is dominated by CO_2 (95%) and N_2 (2.7%), containing very small amounts of O_2 (0.13%) and H_2O (0.03%). The ionosphere of Mars shows, however, many similarities with the Earth's ionosphere, despite strong differences in the composition of the neutral atmosphere. For instance, the dominating ion species in the ionosphere is oxygen[4] (mainly O^+ at the Earth and O_2^+ at Mars).

The solar-wind interaction with a planet having a conducting ionosphere is associated with a transfer of energy and momentum from the solar wind to the topside ionosphere. This results in a heating and loss of plasma from the planetary ionosphere, and consequently also a loss of atmosphere from the planet. Theoretically, assuming a complete transfer of solar-wind momentum from ions (velocity $v_{sw} \approx 400\ km\ s^{-1}$) impinging on the topside of Mars to the ionospheric ions until they reach the escape velocity ($v_{esc} \approx 5.0\ km\ s^{-1}$ on Mars), the escape flux could be 80-times higher than the solar-wind (proton) influx. Thus, through a martian central tail with cross-section $\sim 5 \times 10^{13}\ m^2$ a (proton) flux of $\sim 7 \times 10^{27}$ ions s^{-1} may escape as a result of the momentum exchange with a solar wind of density $5\ cm^{-3}$. If the escaping particles are oxygen atoms the maximum escape rate would be 16 times lower ($\sim 4 \times 10^{26}$ ions s^{-1}). This corresponds to a maximum theoretical escape rate of the ionosphere of $\sim 11\ kg\ s^{-1}$. Thus, the present solar-wind interaction with the martian upper ionosphere is capable of causing a massive erosion of the atmosphere from Mars.

The average total O^+ ion escape observed in the tail was $\sim 2 \times 10^{25}$ ion s^{-1}, corresponding to an oxygen loss rate of about $0.5\ kg\ s^{-1}$. Taking into account the observed molecular-ion escape (such as O_2^+, CO_2^+) and the H^+ ion escape implies that the total escape of volatiles from Mars because of the solar-wind interaction is at least $1\ kg\ s^{-1}$.

The first plasma composition results from the martian magnetosphere obtained by the ASPERA experiment on board the Soviet Phobos spacecraft show that the escape of plasma from the ionosphere has characteristics similar to those found near the Earth. In the central tail upward-escaping ions are accelerated up to keV energies. The massive escape of ionospheric plasma, however, is contained in the martian tail boundary where the Mars/solar-wind interaction is more cometary.

In view of the inventory of volatiles (in both the atmosphere and the hydrosphere) at the Earth, the terrestrial net loss of $\sim 2\ kg\ s^{-1}$ (2×10^{26} ions s^{-1}, see ref. 5, for example) from the upper ionosphere through the magnetotail is of minor importance. At this rate, it will take at least 10^9 yr to evacuate the present atmospheric oxygen content of the Earth. Because the mass of Mars is ten times smaller, a similar outflow for Mars is, however, quite significant. At the present rate, it will take $< 10^8$ yr to evacuate the oxygen content of a ~ 7 mbar martian atmosphere (chemically bound in CO_2). The present loss rate of oxygen is equivalent to the loss of a layer of 1 m of water on Mars in 4.5×10^9 yr. Because the major ionospheric loss is associated with the solar-wind interaction in the dayside ionosphere, a higher atmospheric pressure on Mars would lead to a more extended exosphere and ionosphere and a correspondingly higher escape rate. As noted previously, an escape rate that is ten times higher than the measured one is theoretically possible. Thus, if Mars also lacked a significant magnetic field in the past, it implies that the planet has been exposed to a continuous atmospheric erosion through the solar-wind interaction. The lack of sufficiently strong intrinsic magnetic fields may be the reason why both Venus and Mars lost most of the water collected during the accretion process. □

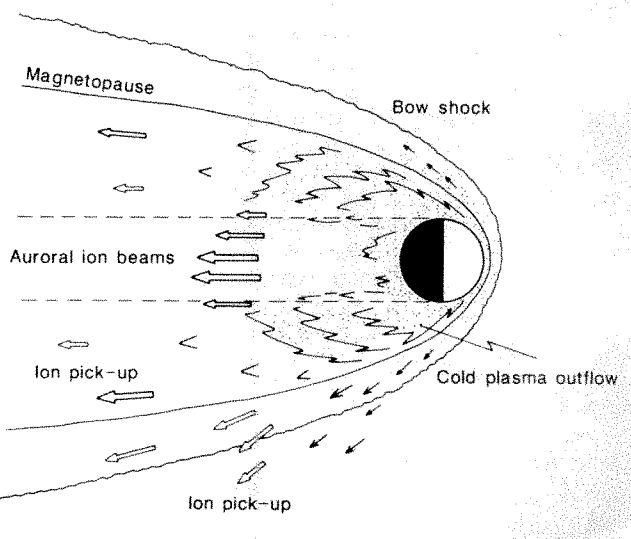

FIG. 4 Representation of the ionospheric ion outflow from Mars. The diagram illustrates the properties of the main ionospheric ion-escape regions, the tail boundary and the central tail.

UNLIKE plasma instruments used on previous space missions to Mars, the TAUS instrument on Phobos 2 was designed so that the energy per charge and angular spectra of three species of ions could be measured separately. These species were H^+ and He^{2+} characteristic of the solar wind, and 'heavy ions' collected in one integral channel covering the mass per charge (M/q) range 3 to ∞, which we anticipated to find predominantly in the near-martian regime. In all spacecraft orbits around Mars we found a sharp boundary, separating the shocked solar wind from the martian magnetosphere which was characterized by the absence of solar-wind-like plasma. As the plasma inside the magnetosphere, and particularly in the tail, was dominated by heavy ions with number densities orders of magnitude higher than found in the solar wind, we assumed it was mainly of martian origin. Typically, heavy ions of low tailward flow velocity were seen near the boundary of the magnetotail, whereas high-speed tailward plasma flows of such ions were detected deeper inside the tail, a region not investigated before. Near the centre of the martian magnetotail a plasma regime, comparable to the terrestrial as well as the venusian[1] plasma sheet, was detected, characterized by highly supersonic tailward streams of heavy ions. The flux of planetary ions leaving Mars through its magnetotail is tentatively estimated to be of the order of a few times 10^{25} s^{-1}. Such loss rates would be significant for the dissipation of the martian atmosphere on cosmological timescales.

The instruments previously used for investigating the martian plasma environment were either plasma cups or curved electrostatic analysers by which different types of ions generally cannot be distinguished. To resolve this deficiency, the TAUS spectrometer, which uses electric and magnetic fields for separating ions according to their M/q, was specially designed for investigation of the solar wind and its interaction with Mars. The instrument features a field of view of ~40° × 40° centred on the nominal direction towards the Sun and divided into 8 × 8 channels for angular resolution. Its energy per charge (E/q) range of ~30 V–6 kV is subdivided into 32 channels. In the H^+ and He^{2+} channels, three-dimensional (3D) spectra, resolved in energy, azimuth and elevation can be measured whereas the spectra in the heavy-ion channel can only be resolved in E/q and elevation. The sensitivity of the instrument is nearly constant over its entire field of view but depends on the ion speed. The one-count detection limit for density, for example for a cold O^+ plasma with a speed of 100 km s^{-1}, would be ~1×10^{-3} cm^{-3}. As a data rate of only ~10 bits s^{-1} was available for most of the time, the instrument's high resolution in velocity space and time could not be fully exploited; instead the information had to be compressed on board.

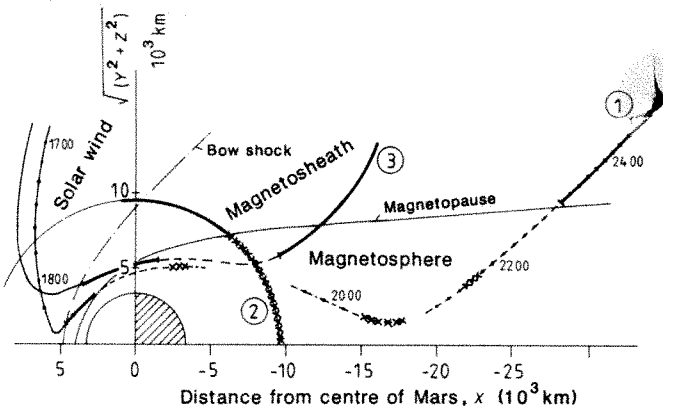

FIG. 1 The orbits of Phobos 2 on 1 February, ①; and on 2 March, ②; and of Mars-5 on 13 February 1974, ③; are given in cylindrical, Mars-centred solar-ecliptic coordinates. Approximate positions of the most important boundaries, the bow shock and the magnetopause, as derived from TAUS data, are shown, too. Along orbit ①, time tags are given for easy reference to Fig. 2. Those parts of the trajectories where the spacecraft passed through solar wind are indicated by thin full lines, shocked solar wind is marked by enhanced full lines, and the passage through the martian magnetosphere is indicated by dashed lines. Crosses on the dashed lines show the positions where supersonically tailward streaming plasma was found. Gaps in the orbital lines indicate that no data were received.

As the first orbit of the Phobos 2 spacecraft around Mars, on 1–2 February, provided a good survey of the martian plasma environment, we will demonstrate our initial results using mainly these data. The Phobos spacecraft trajectory for this period is shown in Fig. 1 in Mars-centred solar-ecliptic cylindrical coordinates.

In Fig. 2*a*, we present 4-min averages of proton count rates as a function of particle energy, with time progressing from bottom to top. The lower spectra show that the solar wind with a speed of ~750 km s^{-1} and a temperature of ~150×10^3 K was steady. The sudden decrease of mean energy and broadening of the spectra at ~18:25 UT is the signature of the martian bow shock, which indicates the first major interaction of the solar wind with the 'obstacle' Mars.

Between the bow shock crossing and the transition through the magnetopause at ~18:37 UT, the observed spectra were broad and fluctuating as is typical of shocked solar wind in the magnetosheath. On crossing the magnetopause, the proton fluxes fell below the sensitivity threshold of our instrument and remained at this level everywhere in the martian magnetosphere up to ~23:10 UT, when broad turbulent proton spectra indicate that the spacecraft was in the magnetosheath again.

These characteristic variations of proton spectra in near-martian space have been observed before, for example by instruments on spacecraft Mars 5 (ref. 2). Bow-shock positions determined by Phobos instruments are also close to those obtained in previous martian missions.

The most interesting new result of the Phobos plasma

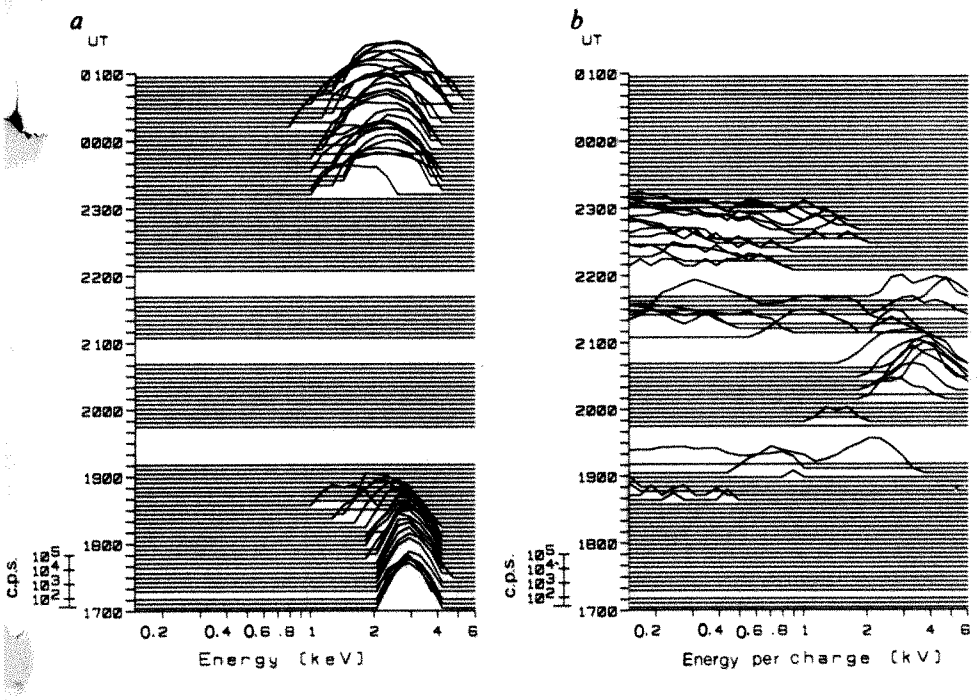

FIG. 2 Four-minute averages of energy-per-charge spectra in terms of count rates of protons (*a*) and heavy ions (*b*) as a function of time including the passage through the martian magnetosphere of the Phobos 2 spacecraft during its first martian orbit on 1–2 February are presented. The foot-lines of the spectra correspond to the one-count level or 40 counts per second. Average background count rates have been subtracted, and cross talk from the proton channel to the heavy-ion channel removed. Blanks indicate data gaps; c.p.s., counts per second.

measurements is the discovery of strong fluxes of heavy ions in the martian magnetosphere. Figures 2*b* and 3*b* show examples of E/q spectra in terms of count rates recorded by the TAUS heavy-ion channel while the spacecraft was crossing the martian magnetosphere. Figure 2*b* shows that heavy ions with energies per charge $\leqslant 1$ kV were observed on 1 February immediately after the entry of the spacecraft into the magnetosphere. Although the maximum ion energy per charge is rather high, the plasma may be nearly stagnant because the maximum of the distribution is found in the lowest E/q channels. By comparison with the opposite side of the magnetotail (22:00–23:00 UT) and with other orbits (see Fig. 3*b*) it appears that this type of heavy-ion plasma is typical of the boundary region of the martian magnetosphere traversed by the Phobos spacecraft. However, in a few cases, supersonically tailward-streaming plasma was observed just inward of the magnetopause as well.

As the spacecraft proceeds further into the magnetotail, a high-energy peak develops in the spectra that eventually, near the centre of the tail, remains as the sole feature of the distributions. This means that the plasma has a well-defined, highly supersonic tailward flow speed in that region. As this type of fast tailward streaming plasma was also found in other orbits (see Fig. 3*b*) always near to the region where the tailward component of the magnetic field reverses sign and the total field strength is close to a minimum, we conclude that this is the region corresponding to the plasma sheet in the geomagnetic tail. However, whereas the Earth's plasma sheet is normally populated by solar-wind-type plasma, and heavy ions of ionospheric origin are only found in appreciable amounts during substorms, the martian plasma sheet seems to consist, at least in its central region, of supersonically tailward-streaming heavy-ion plasma most of the time. Protons were seen only in a few cases. Inspection of all of the tail crossings shows that the position of the martian plasma sheet is considerably more vari-

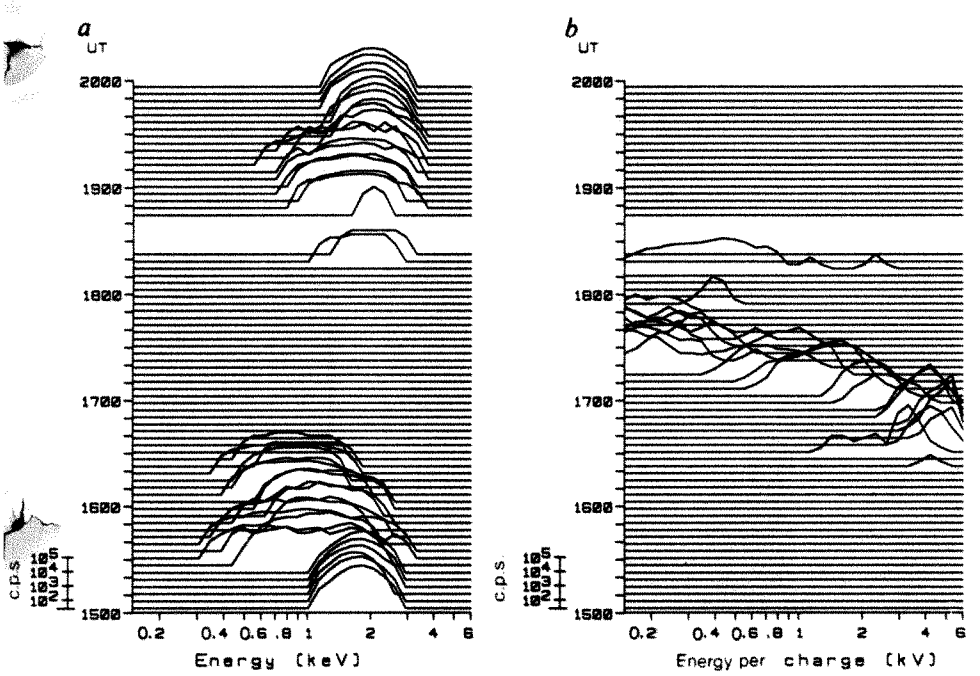

FIG. 3 Energy-per-charge spectra are shown for the circular orbit on 2 March 1989 (see curve ② in Fig. 1) in the same format as in Fig. 2. In the proton data (*a*), the inbound and outbound bow-shock crossings at 15:28 UT and 19:22 UT respectively are clearly visible. Although the maximum flow speed of heavy ions (*b*) was found close to the boundary of the magnetotail, its position again coincides with the reversal of the axial component of the magnetic field, typical of the plasma sheet, and the plasma characteristics are similar to those presented in Fig. 2 where the maximum of the flow speed was measured close to the centre of the tail.

able than the Earth's; also, the density and speed of the plasma found are different from orbit to orbit. This is probably due to the large amount of 'induced' magnetic field in the martian magnetosphere introducing most of the interplanetary magnetic field fluctuations into the tail.

The ion-velocity distributions found in the martian plasma sheet are also worthy of note. As an example, two two-dimensional spectra measured in the plasma sheet region during the second and the fourth elliptical orbit, at a distance of $\sim 1.5 \times 10^4$ km from the centre of Mars, are shown in Fig. 4. Although the mean tailward velocities of the plasma sheet ions were vastly different, the distributions are similar: the transverse (in the instrument's frame of reference) velocity spread or temperature is much higher than the longitudinal one and the resulting anisotropy of ~7 is probably one of the largest ever observed in a plasma anywhere. These velocity distributions are regarded as a very important diagnostic tool for the identification of the ion-acceleration processes at work.

Another interesting aspect of these E/q distributions is that they are only singly peaked. This strongly indicates that the observed plasma consists essentially of one ion species only. The high density of these heavy ions, which exceeds that of the heavy ions ($M/q \geq 3$) in the solar wind by about three orders of magnitude, leaves us no choice but to assume that they are of martian origin. The known composition of the upper martian ionosphere[3] from where they have probably been removed makes it highly probable that they are O^+.

It is of interest to estimate the total flux of heavy ions lost by the planet through its magnetotail. As the largest ion fluxes are observed in the plasma sheet, and we do not yet know much about plasma-sheet structure and variation with time, this initial evaluation must be regarded as tentative. We assume that we do not miss a major part of the ion flux as a result of the limited field of view of our instrument and take the width of the plasma sheet to be one martian diameter, $2R_M$, and to extend over the whole tail diameter of $\sim 4.5R_M$. From the data obtained during the second elliptical orbit the density and velocity of O^+ ions in the plasma sheet can be estimated to be of the order of 1.5 cm^{-3}, and 150 km s^{-1}, respectively. This results in a total tailward flux of O^+ ions of $\sim 2 \times 10^{25}$ s^{-1}, meaning that Mars would be deprived of all of its presently existing atmosphere after $\sim 10^9$ years, if the mass loss rate did not change with time and no other loss or gain processes existed. □

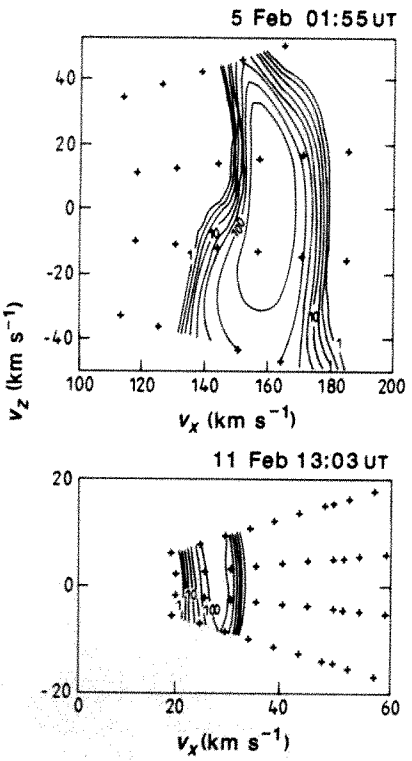

FIG. 4 Contour plots of count rates (to first order representing two-dimensional velocity distributions) obtained in the heavy-ion channel during the second (top) and fourth (bottom) orbit near the plasma sheet. Lines are spaced logarithmically by a factor of $\sqrt[3]{10}$ between adjacent contours. Crosses indicate the centres of the measurement channels. Conversion from E/q to velocity was made by assuming that the ions are O^+. V_x is the anti-sunward component of the velocity, and V_z is perpendicular to V_x. (The direction of V_z relative to the ecliptic plane cannot yet be given because of still missing information on the roll angle of the spacecraft.)

THE highly elliptical orbits of the Phobos 2 spacecraft, early in February 1989, proved particularly useful for plasma and field investigations of the martian environment. The low-altitude (~860 km) pericentres and the deep penetration into the magnetotail provided excellent opportunities to explore new and important regions. Here we present preliminary results of electron and ion measurements in the vicinity of Mars with the hyperbolic analyser in the retarding potential mode (HARP). HARP is a differential electrostatic analyser, simultaneously covering eight directions arranged in a fan-shaped geometry, in the anti-solar hemisphere. The angular resolution is ~20°, the energy resolution ~10%. During the first two elliptical orbits, to be discussed here, electrons from 3.4 to 550 eV and ions from 0.25 to 550 eV were measured in 25 and 50 logarithmic energy steps, respectively. The energy distribution of electrons in the magnetosheath was found to be generally characterized by two distinct peaks. A fairly hot electron component was discovered in the plasma sheet of the areo-magnetic tail.

The HARP differential electrostatic analyser allowed the measurement of charged particles within an energy (or, more precisely, energy per charge) range of ~0.2–800 eV. The energy steps of the instrument were adjustable, that is, a more detailed study of some selected energy intervals was also possible by telecommand. Particles were measured simultaneously in eight sectors (20° × 10° each), symmetrically arranged relative to the anti-solar axis. The actual instrument package on the Phobos 2 spacecraft consisted of two independent and identical sensors. The sensors were mounted to point at 90° from each other. Each unit had four independent anodes. The combined directional

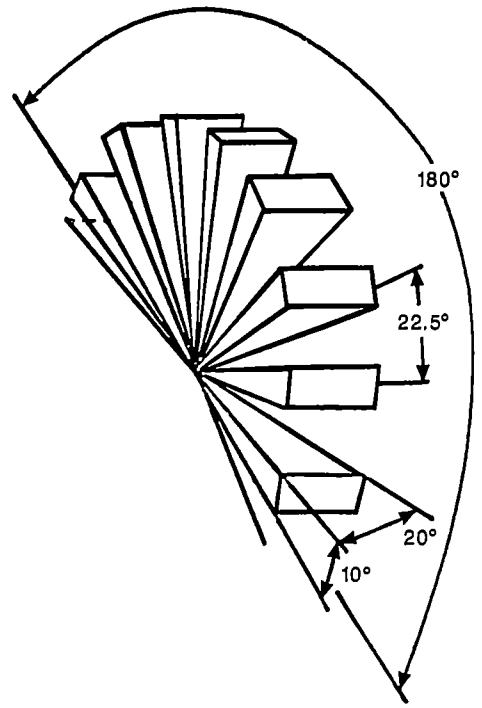

FIG. 1 Directional coverage of the HARP device (centred on the anti-solar direction).

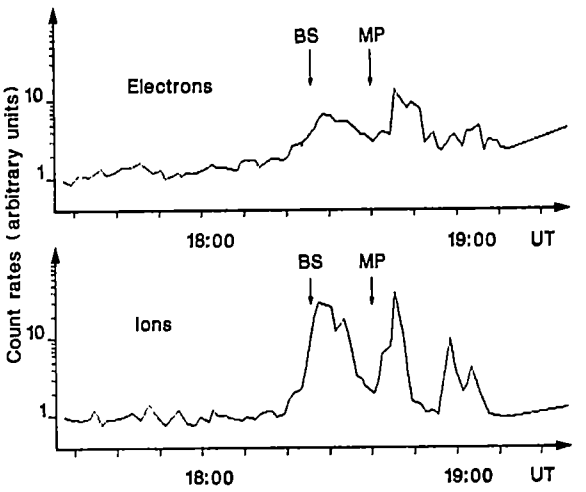

FIG. 2 Electron and ion total count rates as a function of time before and during Mars encounter on the first elliptical orbit of the Phobos spacecraft. BS, bow shock; MP, magnetopause.

coverage is shown in Fig. 1. In the normal, three-axis-stabilized mode of the spacecraft, the viewing directions were in a plane perpendicular to the ecliptic. During the two orbits discussed here there was a slow rotation around the symmetry axis, and the precise attitudes as a function of time are not yet available. The Phobos HARP device[1,2] was specifically developed for this project. Earlier versions[3] were used in terrestrial ionospheric research.

The instrument's energy coverage during the first two elliptical orbits was as specified above. The integration period at each energy step was 1 s. The electron and ion measurements were made sequentially, which means that a complete electron/ion energy and angular distribution was obtained in 75 s. During the high-bit-rate telemetry regime covering the Mars encounters, practically full telemetry coverage was available.

The results of the electron measurements are highlighted here. Results of the ion measurements are only used for comparison in Fig. 2, where total count rates of electrons and ions (summed over energy and direction) are plotted as a function of time during the first elliptical orbit as the spacecraft approached the planet. The location of the bow shock and planetopause (magnetopause) depends on how these boundaries are defined in terms of the measured parameters. For example, the bow-shock crossing as indicated by the appearance of high-energy electron fluxes differed by ~5 min from the bow-shock position defined by the magnetic-field experimenters as the location of an observable jump in the magnitude of the magnetic field. Further and more careful intercomparisons and self-consistent definitions will be needed in the future to resolve these issues. In Fig. 2 we indicate the bow shock and planetopause/magnetopause crossing locations chosen by the magnetic field experimenters[4]; the increase of both electron and ion fluxes in the vicinity of the bow shock is clearly visible.

Spectral information provides a more detailed description of the dynamics of electron populations. As an example, the change of the spectral character of the measured electron flux in one directional channel (56° from the symmetry axis) is given in Fig.

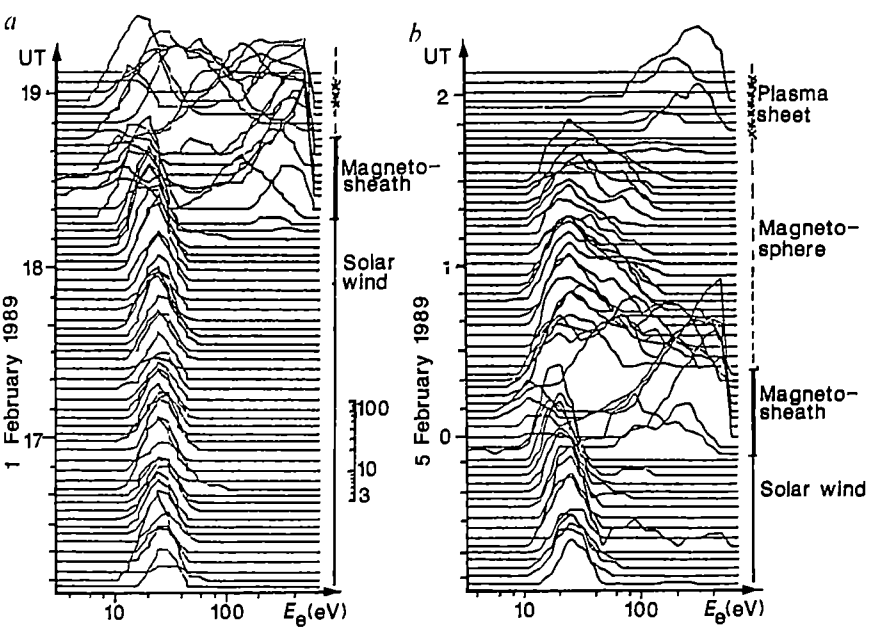

FIG. 3 Variation in time of the energy spectra measured by the HARP device during *a* the first and *b* the second Mars encounter of the Phobos spacecraft.

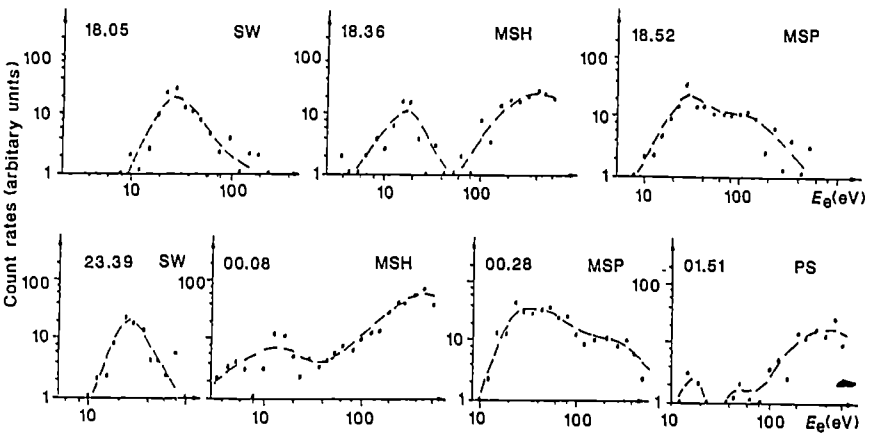

FIG. 4 Characteristic energy spectra (count rates as a function of energy) on the first two highly elliptic orbits. *a*, 1 February 1989; *b*, 4–5 February 1989. SW, solar wind; MSH, magnetosheath; MSP, magnetosphere; PS, plasma sheet.

3 for the first two elliptical orbits. (The 'spectra' represented here are really count rates proportional to energy flux, as usually measured by electrostatic analysers. The baselines represent 3 counts s^{-1} even when the measured count rate was lower.) For the first orbit, the sharp change in the spectral shape of the electron flux indicates a bow-shock position at 18:20 UT on 1 February, corresponding to a distance of ~1,500 km from the surface of the planet and a solar zenith angle (SZA) of 10°. For the second orbit, the spectral change, indicating the bow shock, occurred at 23:55 UT on 4 February, corresponding to a distance from the surface of ~1,700 km and a SZA of 11°. The periapsis of the orbits at a distance of ~860 km from the surface was at 18:39:37 UT on 1 February and 0:15:47 UT on 5 February.

The bow-shock crossing times determined from the HARP electron spectra are in reasonable agreement with those obtained by the MAGMA magnetometer[4] and the TAUS ion spectrometer[5]. The changes in the total flux and energy distribution of the measured spectra inside the bow shock are clear indications of changing plasma regimes. The solar-wind interaction processes at Mars are believed to be different from those at Earth and Venus, therefore the accepted terminologies used to delineate different regimes at these planets may not be quite appropriate to Mars. However, it is premature to coin new boundary definitions; therefore, we use here the terminology accepted for the terrestrial magnetosphere to label the different regions in Fig. 3, as delineated by the observed spectra. The data presented in Fig. 3 indicate that the electron spectra observed in the tail region of the planet are similar to those in the region just inside the bow shock. The energy spectra clearly show that electrons with energies $\gg$100 eV are present inside the bow shock in the magnetosheath.

Figure 4 presents typical spectra measured in various regions of the magnetosphere. (These spectra represent uncorrected count rates, so even single counts are included, in contrast to the baselines of Fig. 3.) In the magnetosheath the electron energy distribution is strongly non-maxwellian, often showing a distinct double peak; significant fluxes are present at energies beyond the energy limit of HARP. In the inner magnetosphere the electron fluxes were found to be generally more isotropic than in the magnetosheath. The corresponding energy distributions had a rather broad maximum, extending from ~20 to 150 eV. Most spectra are also characterized by a double-peak structure. In the shadow of the planet, the energy distributions of electrons, as mentioned above, are similar to those observed in the magnetosheath. This region, in the tail, is referred to as the plasma sheet. Before reaching the tail, the intensity of the electron fluxes dropped and showed strong fluctuations. Our identification of the plasmaphysical regions, as indicated in Figs 3 and 4, was supported by the TAUS ion measurements on the Phobos spacecraft[5].

Summarizing, the measurements of electron spectra along the orbit show sharp changes in both flux levels and in spectral shapes as the spacecraft crosses the bow shock, magnetopause and plasma sheet. The similarity of the observed electron spectra in the magnetosheath and the plasma sheet is likely to be an indication that the plasma sources and/or acceleration processes are similar in these regions. The plasma sheet with accelerated electrons in the inner magnetotail of Mars was detected for the first time with the HARP experiment on board the Phobos spacecraft.

The physical mechanisms responsible for the acceleration of the electrons inside the bow shock and the creation of double-peaked energy distributions are not known at this time. However, further analysis of the HARP data and careful comparisons with the observations of other field and particle experiments carried by the Phobos spacecraft, as well as with previous observations[6], will help to advance our understanding of Mars's plasma environment. □

THE twin-telescope particle-detector system, SLED, aboard Phobos 2 recorded flux enhancements in the range 30–350 keV in the same general location in the close environment of Mars, over eight days at ~900 km altitude in three successive elliptical orbits. Here we present possible interpretations of these observations. Energy-related particle shadowing by the body of Mars was also detected, and the data indicate that this effect occurred in <20% of the 114 circular orbits around Mars because of the nutation

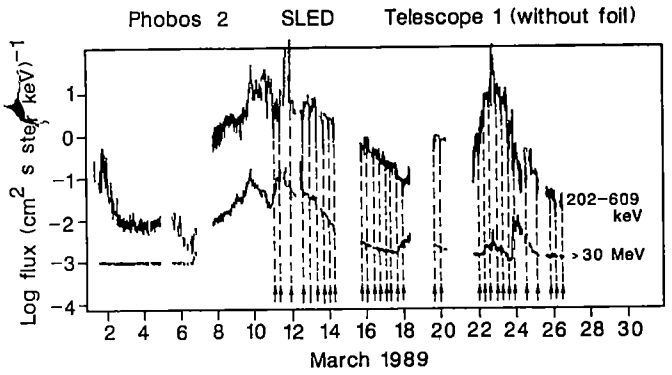

FIG. 1 In the circular orbits around Mars (~6,900 km) in March 1989 the particle fluxes observed by SLED were enhanced because of solar and interplanetary activity. Arrows (bottom) indicate significant depressions in flux resulting from the shadowing by the body of the planet.

of the spacecraft. We discuss the influence of magnetic fields in allowing particles to reach the detector under potentially screened conditions.

The charged-particle detector SLED aboard the three-axis-stabilized Phobos 2 spacecraft was designed to measure the flux of ions and electrons simultaneously in the 30 keV to a few MeV range[1]. The instrument used silicon surface barrier detectors, two in each of the two telescopes viewing in the same direction. One telescope (Te 2) was covered by a thin Al-foil (500 μg cm^{-2} Al on Mylar) whereas the other telescope (Te 1) was 'open'. The front detectors of both telescopes were covered by a 15 μg cm^{-2} Al-layer. Low-energy protons and electrons could be distinguished[2], as the foil-telescope stopped ions up to 350 keV (with respect to protons) due to the Al-foil and to the Al-layer on the front detector. The geometric factor of each telescope was 0.21 cm^2 ster and the FOV (field of view) axis, with a 40° apex angle, was in the ecliptic plane at 55° to the west of the sunward direction (nominal direction of the interplanetary magnetic field at Mars).

Back detectors were used to discriminate particles which penetrated the front detectors. In addition, each telescope was shielded by 5.6 g cm^{-2} Al and Ta to prevent protons with energies <70 MeV and electrons <10 MeV from reaching the detector systems. Thus, six different energy channels for each telescope could be defined. In the open telescope Te 1, ions and electrons were recorded over the following ranges: channels C1 (30–50 keV), C2 (50–200 keV), C3 (200–600 keV), C4 (0.6–3.2 MeV), C5 (3.2–4.5 MeV), C6 (>30 MeV). In the foil-covered 'electron' telescope Te 2, the energy ranges covered by individual channels were very similar to the above. Channels 6 in both telescopes represent the count rates of the back detectors. In Te 2, protons with energies <350 keV, helium < 1.6 MeV and oxygen ions <8 MeV were stopped in the Al-layers. SLED was the first instrument to approach Mars as closely as 867 km, capable of measuring particles at energies ≥30 keV (refs 3–5).

During the interval from switch-on (25 July 1988) until arrival at Mars (29 January 1989), SLED monitored interplanetary intensity variations with signatures typical of solar minimum conditions (co-rotating interaction regions) under gradual replacement by signatures characterizing solar maximum conditions (produced by transient events such as flares and coronal-mass ejections). Figure 1 provides an example of solar-flare-related particle enhancements recorded by SLED in C3 and C6 of Te 1 when close to Mars in successive circular orbits around the planet during March 1989. These data resemble those observed near the Earth by the satellite GOES 7 (ref. 6).

In addition to observations during the cruise phase, particle measurements were also carried out during four elliptical orbits about Mars, 1–14 February 1989 (pericentre 867 km), and during the following single elliptical and 114 circular orbits (height above Mars 6,000 km). At the time of the first close elliptical orbit, the environment of the planet was greatly disturbed by the presence of particles of solar origin with energies up to a few MeV. Figure 2 (left-hand panels) shows data obtained during the relatively quiet interplanetary conditions characterizing orbit 2 and in more disturbed conditions for orbits 3 and 4. Complementary drawings showing the spacecraft trajectory in polar coordinates (times indicated are in UT) and the position during each orbit of the pericentre (PC), as well as the locations during orbits 2 and 3 of the bow shock and magnetopause, are presented in the right-hand panels. These latter data were provided by the cold plasma (TAUS) and magnetic field (MAGMA) experimenters. Figure 2 shows that, on 5 February 1989, a well-defined enhancement in fluxes increasing by a value of about two orders of magnitude and a duration of 8 min was recorded near pericentre in Te 1, C1 (30–50 keV), when the spacecraft was ~900 km above the planet. A less pronounced peak of about half an order of magnitude was recorded in C2 (50–200 keV). No enhancement was observed in the foil telescope Te 2, so that the increases recorded in Te 1 seem to have been produced by ions in the range 30–200 keV.

In orbit 3 (see Fig. 2) particle fluxes increased in Te 1, channels 1–3, again near pericentre. The duration of this effect was ~26 min. The largest enhancement occurred in the lowest energy range. The peaks of the enhancements in C2 and C3 occurred ~5 min earlier than that in C1. No special response was observed in Te 2.

In orbit 4 there was a telemetry gap close to pericentre but, as shown in Fig. 2, from after about 4 min, the declining phase of a flux enhancement was present in the data of Te 1, C1. Again, Te 2 showed no flux enhancement.

Positive responses in Te 1 and no responses in Te 2 at the times of pericentre passages may suggest pulse pile-up caused by lower-energy particles[7]. For SLED, baseline restoration is applied, the pulse-shaping time constant is 0.3 μs, the pulse length is 1 μs, and the coincidence resolution time is 1 μs. These factors prevent a pulse pile-up up to 10^5 c.p.s. The maximum fluxes observed near pericentre, however, do not exceed 10^3 c.p.s.

The fact that particle increases were recorded by Te 1 in the same general location, <900 km above the planet over ~8 days, therefore suggests the existence of a zone of enhanced radiation inside the martian environment. By identifying the nature and origin of this radiation, SLED could make an important contribution to the solution of an essential, yet unresolved, question concerning the geophysics of Mars, namely whether or not this planet has an intrinsic magnetic field and thus a magnetosphere, like the Earth.

If Mars indeed possesses a magnetosphere, these observed enhancements could represent a zone of trapped ion radiation (30–350 keV) similar to the van Allen belt in the inner part of the Earth's magnetosphere. In the absence of unambiguous data concerning the overall structure of the ambient magnetic field, this possibility is not excluded. Because the gyroradii of these ions are approximately equal to the height of the spacecraft above Mars, however, these particles could only be quasitrapped, as they would be quickly lost because of their interaction with the dense atmospheric layers of the planet. This provides one possible explanation of the observation that, during orbit 3, the position of maximum flux recorded in the channels of Te 1 shifted with time towards lower energies, with the largest flux detected in the lowest-energy channel. On the other hand, the interaction of a martian magnetosphere with the interplanetary magnetized medium would possibly also lead to a local and sporadic merging of planetary with interplanetary magnetic field lines at the front side of the planet and thus, like at Earth, to an acceleration of charged particles. This mechanism could conceivably provide a source for the observed <350 keV ions, which could then propagate along the magnetopause boundary layer from the day to the nightside of the planet, as already

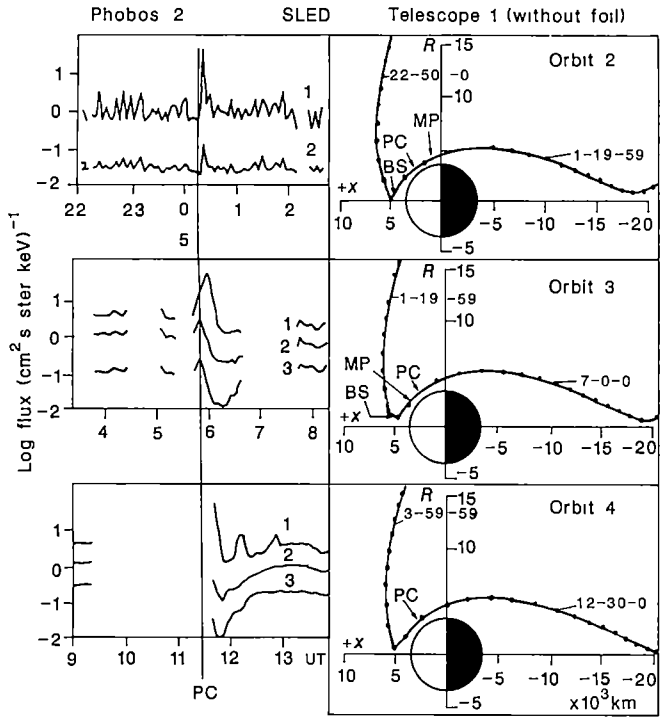

FIG. 2 Particle fluxes (left-hand panels) measured with Te 1 in the highly eccentric orbits 2, 3 and 4 at 4, 8 and 11 February 1989, respectively. In all three orbits clear flux enhancements were observed just after passing pericentre (PC) at ~900 km altitude. The energy bands are 1, 30–50 keV, 2, 50–200 keV; and 3, 200–600 keV. The right-hand panels show for the same periods the radial distance R (in 1,000 km) of the spacecraft from the x axis (Mars–Sun line) and the positions of the bow shock (BS) and the magnetopause (MP) as measured by the magnetic field and plasma experiments

observed in the case of the Earth's magnetosphere[8]. It is interesting to note that, at the part of the orbital trajectory concerned, SLED viewed directly along the surface of the magnetopause.

A more general explanation concerning the origin of these observed enhancements could alternatively rest in the fact that the magnetic-field observations indicated a pronounced compression of field lines close to the planet[9]. Such a compression would also increase the density of the ambient plasma and could simultaneously lead to an adiabatic acceleration of suprathermal particles to keV energies inside the martian environment. The acceleration of martian ions, such as oxygen, by the pick-up process in the solar wind can be neglected (provided no additional acceleration by other processes is imposed), as the expected energy would be ~60 keV and therefore below the threshold of the detectors with respect to oxygen.

At present other, more mundane, explanations cannot be ruled out entirely: for example, the observed enhancements could simply be caused by local changes in the angular distribution of particles as the spacecraft traversed different plasma regimes. For directed flux, an intensity enhancement would be observed if the angle between the flow direction and the instrument aperture became favourable. As is well known, the magnetic field changes its direction at the magnetopause quite substantially. Moreover, the possibility that sunlight reflected from the body of the planet (rather than from its thin atmosphere) may have contributed to the observed intensity increases cannot be excluded entirely. As the front detector of Te 1 is only shielded by 15 μg cm^{-2} Al, this detector will be sensitive to sunlight. However, the observed maximum fluxes near pericentre during orbit 3 cannot solely be caused by photons. Because photons will normally not produce a time dispersion in the time-intensity profiles, and the photon fluxes reflected from Mars, when taking the photon fluxes of the Sun at 1 AU (ref. 10), the albedo of Mars of ~10% and the characteristics of SLED into account, can hardly contribute to the observed count rates of ~10^3 c.p.s. and, at the same time, provide responses to C3 (200–600 keV). Yet the effect of sunlight must be investigated in more detail when adequate information concerning the attitude of the spacecraft becomes available. Finally, the possibility that the observed intensity increases are a result of bremsstrahlung[5], produced by low-energy electrons trapped along magnetic field lines, can be excluded, as the electron telescope Te 2 did not detect any electron fluxes.

An additional feature shown by the data of Fig. 2 from orbits 3 and 4, is the depression in fluxes by about one order of magnitude, which is seen particularly clearly in the data of Te 1, C3, C4 and C5. Although, as mentioned above, particle enhancements were not detected in Te 2, the depressions in fluxes recorded by Te 1 were clearly present in the data of C3 and C4 of Te 2. Again, depressions in fluxes recorded during orbit 4 in Te 1, C2, C3, C4 and C5 had well-defined counterparts in Te 2, C3 and C4. These decreases were energy-dependent in both telescopes.

Shadowing[11] by the planet Mars over that part of the orbit where the apertures are directed towards the planet is involved in producing these observed depressions in intensity. It is noted that data taken during 114 circular orbits at an altitude above the planet of 6,000 km indicate that marked decreases in the particle fluxes occurred in <20% of these revolutions, probably because of the nutation of the spacecraft. Successive instances of the occurrence of particle shadowing during the succession of flare-related particle enhancements recorded by SLED when in circular orbit during March 1989 are indicated by arrows in Fig. 1. This sequence seems to indicate the influence of magnetic effects in allowing particles to arrive at the detector during disturbed interplanetary conditions, even in situations where the solid angle of the aperture of the instrument was completely filled by the body of the planet. □

T-cell receptor cross-linking transiently stimulates adhesiveness through LFA-1

Michael L. Dustin & Timothy A. Springer

Center for Blood Research, 800 Huntington Avenue, Boston; and Committee on Cell and Developmental Biology and Department of Pathology, Harvard Medical School, Boston, Massachusetts 02115, USA

Effective interaction between T cells and their targets requires that recognition of specific antigen be coordinated with increased cell–cell adhesion. We show that antigen–receptor cross-linking increases the strength of the adhesion mechanism between lymphocyte function-associated molecule-1 (LFA-1) and intercellular adhesion molecules (ICAMs), with intracellular signals transmitted from the T-cell antigen receptor to the LFA-1 adhesion molecule. The increase in avidity is rapid and transient, providing a dynamic mechanism for antigen-specific regulation of lymphocyte adhesion and de-adhesion.

T-CELL immune recognition requires adhesion receptors as well as the T-cell receptor (TCR), as shown by the ability of monoclonal antibodies directed against these structures to inhibit antigen-specific responses[1]. T-cell adhesion receptors include LFA-1, which binds to its counter receptors ICAM-1 and ICAM-2 (refs 2–4), and CD2, which binds to its counter receptor LFA-3 (ref. 5). LFA-1 is a member of the integrin family, a group of extracellular matrix and cell-adhesion receptors which integrate the extracellular environment with the cytoskeleton[6–8]. The other molecules, ICAM-1, ICAM-2, CD2 and LFA-3 are members of the immunoglobulin superfamily[9]. One unresolved question is how the TCR and adhesion receptors cooperate to balance the competing needs for sensitive antigen recognition and stable cell–cell adhesion. At one extreme, requiring TCR interaction with antigen to contribute the antigen-specific adhesive component, would need a large number of receptor–ligand interactions, lowering the sensitivity of antigen recognition. At the other extreme, strong adhesion of T cells to other cells regardless of antigen expression would lower the efficiency of immune surveillance, as T cells would spend long periods of time in non-productive interactions.

Early studies demonstrated that cytolytic T lymphocytes (CTL) elicited *in vivo* adhered to target cells bearing antigen but not to cells lacking antigen, implying that adhesion was antigen-specific and, by inference, solely due to the TCR[10,11]. With the discovery of adhesion receptors it was initially proposed that these molecules contributed in an additive manner to TCR-specific interactions, so that antigen-specific adhesion could be maintained[12,13], or that they might be involved in an adhesion strengthening step triggered by the TCR[1,14,15]. No evidence for TCR regulation was presented, however, and subsequent studies with CTL lines and clones maintained *in vitro* showed that adhesion was virtually equivalent with both antigen-positive and antigen-negative targets[16,17]. It was proposed that adhesion-molecule interactions preceded TCR binding to antigen, and that the TCR was important only for triggering T-cell effector function[16]; this theory has been widely accepted[18].

Interactions between T lymphocytes and antigen-bearing cells must be reversible. This can be inferred from the existence of circulating T lymphocytes that have previously encountered antigen (memory T lymphocytes) and from studies on CTL. CTL can be observed engaging in repeated cycles of adhesion to target cells, lethal hit delivery and de-adhesion, with a cycle time as short as 15 min[11,14,19]. The mechanism for regulating adhesion and de-adhesion cycles is completely unknown.

We present evidence that LFA-1 function is regulated by phorbol esters and the TCR. Activation of lymphocytes by the TCR rapidly converts LFA-1 to a high-avidity state. TCR engagement thus triggers an adhesion amplification mechanism, allowing antigen-specific adhesion to be driven by a metabolic energy-dependent increase in LFA-1 avidity. The TCR and LFA-1 are coupled by intracellular signalling pathways, as shown by inhibition with dibutyryl cyclic AMP, agents that increase cytosolic cAMP, and the protein kinase inhibitor, staurosporine. The high avidity state of LFA-1 is transient; it peaks 5 to 10 min after TCR stimulation and returns to the low-avidity state by 30 min–2 h, providing a mechanism for de-adhesion.

TABLE 1 Blocking of CD3-stimulated adhesion with monoclonal antibodies

Monoclonal antibody against	OKT3	OKT3 + anti-IgG2a
	^{51}Cr-labelled resting T-cell binding	
Negative control (X63)	50±04	560±01
LFA-1 α (TS1/22)	10±02	1.0±0.2
LFA-1 β (TS1/18)	05±01	06±003
LFA-1 α (TS2/4)	68±06	573±55
ICAM-1 (RR1/1)	20±02	15±02
CD2 (TS2/18)	57±0.3	61.2±5.8

Resting T cells were pretreated with OKT3 (IgG2a; 1:10 culture supernatant) as described in Fig 1 and the indicated antibody, except RR1/1 which was used to pretreat the plates, for 30 min at 4 °C. All antibodies were washed out. Cells were added to wells with or without 2 μg ml^{-1} horse anti-mouse IgG2a. All antibodies except OKT3 are IgG1 so only the anti-CD3 antibody was cross-linked. ICAM-1 density was 1,000 sites μm^{-2} by ^{125}I-labelled RR1/1 binding. Methods were otherwise identical to Fig 1. Monoclonal antibodies, as described in Fig 1. Data shown are representative of two experiments.

Phorbol esters and LFA-1/ICAM-1 adhesion

The first experimental evidence for active regulation of the LFA-1/ICAM-1 adhesion mechanism was the ability of phorbol esters to stimulate LFA-1-and ICAM-1-mediated leukocyte homotypic adhesion[15,20,21]. Adhesion is stimulated rapidly, within one hour, and is not accompanied by any change in cell-surface density of LFA-1 or ICAM-1 (refs 15, 20, 21). It was shown subsequently that LFA-1-mediated adhesion of murine T-cell clones to antigen-negative targets could be enhanced twofold by phorbol 12-myristate-13-acetate (PMA) treatment[22]. Regulation by phorbol esters of LFA-1 avidity, however, could not be distinguished from regulation of ICAM-1 avidity or from a change in some general cellular property such as membrane spreading.

Binding of cells to purified adhesion molecules on inert surfaces is an ideal system to study regulation of adhesion mechanisms. In this situation, only the cell-surface receptor for the purified adhesion molecule is involved in binding, allowing regulation of its avidity (multivalent affinity) to be measured in

isolation from other adhesion mechanisms. The coexistence of ICAMs and LFA-1 on a number of different cell types allowed us to reciprocally assay binding of the same cells to both purified LFA-1 and ICAM-1 on artificial substrates, and so to determine which cell-surface molecule is affected by cellular activation. The hypothesis that PMA stimulates adhesion by increasing the avidity either of cellular LFA-1 or of cellular ICAM-1 predicts that regulation shows sidedness, that is, adhesion to artificial substrates containing purified ICAM-1 or LFA-1 should be differentially affected. Demonstration of sidedness would rule out a general adhesion-promoting effect of phorbol esters, as this should increase adhesion to LFA-1 and ICAM-1 substrates equally. Two distinct LFA-1 counter receptors have been defined, ICAM-1 and ICAM-2. The latter was recently defined by functional complementary DNA cloning[4]. The two immunoglobulin-like domains of ICAM-2 are 35% identical to the two domains closest to the N-terminus of the five immunoglobulin-like domains of ICAM-1. For generality, we have used cells expressing ICAM-1 (JY) as well as those that bind to LFA-1 by an ICAM-1-independent mechanism, which is likely to be through ICAM-2 (SKW3 and resting T cells). Binding of cells to artificial substrates was for six minutes under conditions established to prevent cell-cell aggregation (Fig. 1 legend). Basal binding of JY and SKW3 to ICAM-1 substrates was relatively inefficient over a wide range of ICAM-1 densities (Fig. 1*a*). Adhesion to ICAM-1 was dramatically increased by PMA, however, over a wide range of ICAM-1 densities. By contrast, SKW3 and JY cells adhered to the same extent to LFA-1 substrates in the presence and absence of PMA, although PMA shifted the density of LFA-1 required for half-maximal adhesion by twofold (Fig. 1*b*). Spreading of SKW3 and JY cells on LFA-1 (data not shown) was increased by PMA, which could be the basis of the increased resistance to washing at intermediate LFA-1 densities. Sidedness was even more dramatically illustrated with freshly isolated peripheral blood T lymphocytes. Adhesion to ICAM-1 substrates was almost completely dependent on phorbol ester stimulation (Fig. 1*e*), whereas adhesion to LFA-1 substrates was constitutive and was hardly affected by PMA (Fig. 1*f*). Thus, there is little or no avidity regulation of cell-surface ICAMs and these molecules appear constitutively avid for LFA-1. By contrast, cell-surface LFA-1 is not constitutively avid for ICAM-1, and seems to be converted to a high-avidity state after PMA stimulation.

Temperature effect on LFA-1/ICAM-1 interaction

The LFA-1/ICAM adhesion mechanism is susceptible to inhibition at low temperature (4 °C) in cell-cell binding[14,15] and binding of cells to purified ICAM-1 (ref. 2). This property is relevant

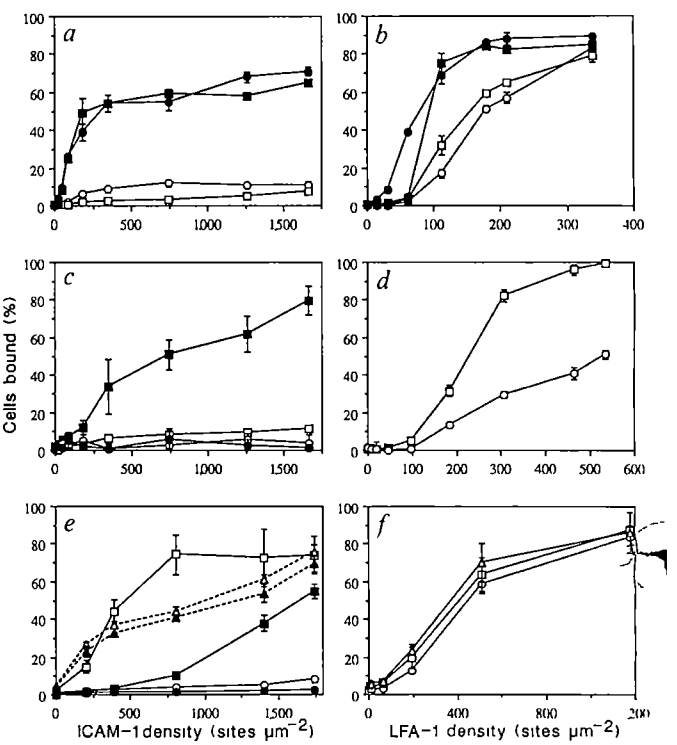

FIG. 1 Effects of activation on binding of cells to purified LFA-1 and ICAM-1 *a*, Binding of JY (circles) and SKW3 (squares) to ICAM-1 adsorbed to plastic without (open) or with (filled) PMA (50 ng ml^{-1}). *b*, same as *a*, binding to LFA-1 adsorbed to plastic. *c*, Binding of JY cells to ICAM-1 at 37 °C (squares) or 4 °C (circles). Cells were treated with PMA (50 ng ml^{-1}) (filled) or with media (open) for 30 min at 37 °C before dispersal and assay. *d*, Binding of JY cells to LFA-1 at 37 °C (squares) or 4 °C (circles). *e*, Binding of resting T cells to ICAM-1; cells pretreated with CD3 monoclonal antibody and then without (open circle) or with (open square) goat anti-mouse IgG, or with PMA (open triangle). Cells treated as above but also pretreated with 2 mM dibutyryl cAMP for 15 min at 24 °C before addition to wells are shown with filled symbols rather than open symbols. *f*, Same symbols as *e*, binding to LFA-1. These data are representative of at least 3 experiments for each group *a–b*; *c–d*, and *e–f*.

METHODS. LFA-1 and ICAM-1 were immunoaffinity purified from JY cell lysates using TS2/4 and RR1/1 sepharose, respectively. ICAM-1 was eluted at pH 12.5 (ref. 2). LFA-1 was eluted at pH 11 5 in the presence of 2 mM $MgCl_2$ (M.L.D. and T.A S., manuscript in preparation). Purified proteins were at 20–100 μg ml^{-1} in buffered saline with 1% octyglucoside (OG) detergent (+2 mM $MgCl_2$ for LFA-1) Purified LFA-1 and ICAM-1 in 1% OG were adsorbed to polystyrene microtitre plate (Flow, Virginia) wells by addition of 5 μl of the detergent solubilized protein to 45 μl of 25 mM Tris, pH 8.0, 0.15 M NaCl, 2 mM $MgCl_2$ (TSM). After 16 h incubation at 4 °C the plates were incubated for 1 h at room temperature in 1% BSA and TSM, and were then washed with assay media. Site numbers were quantified with ^{125}I-labelled RR1/1 or TS2/4 for ICAM-1 or LFA-1, respectively, at 10 μCi μg^{-1} at a final antibody concentration of 10 μg ml^{-1}. JY was pretreated with TS1/22 (anti-LFA-1 α) for binding to LFA-1, and RR1/1 (anti-ICAM-1) for binding to ICAM-1, and free mAb was completely washed out before the assay. This was the best way to prevent PMA-stimulated JY cell aggregation and did not effect binding to the adsorbed proteins. Similar results were obtained without the antibody pretreatment, but PMA-stimulated cells contained many small aggregates (2–10 cells) especially on ICAM-1 substrates. Other cells gave no homotypic aggregation within the 6-min assay period. Resting T cells were isolated from whole blood by plastic adherence and nylon wool filtration and were 97% CD2$^+$, 93% CD3$^+$ and 96% CD6$^+$. Resting T cells were used within 24 h of drawing blood. T cells were pretreated with anti-CD3 monoclonal antibody (Leu4 ascites at 1.500 or OKT3 culture supernatant at 1:10 as indicated) for 30 min at 4 °C and then washed 3 times at 4 °C. In all assays ^{51}Cr labelled cells (1–2×10^4 JY or SKW3, or 5×10^4 resting T cells) were added to wells which contained 50 ng ml^{-1} PMA, 2 μg ml^{-1} goat anti-mouse IgG or neither as indicated above and centrifuged at 10×g for 5 min at 24 °C (or 4 °C for *c&d*). In temperature effect experiments similar results were obtained if cells were allowed to settle at 1×g for 60 min at 4 °C (not shown). Plates were then incubated for 6 min at 37 °C (or 4 °C in *c&d*). Unbound cells were removed by washing, and bound cells removed for γ-counting by incubation for 10 min at 37 °C in medium with 10 mM EDTA. Visual inspection of the number of bound cells per well gave the same results as γ-counting In *a–d*, unbound cells were removed by four complete aspirations of media at assay temperature through an 18 ga needle as described[49]. In *e* and *f*, unbound cells were removed by flicking media from the plates 8 times with 100 μl added between each wash Flicking was more effective for thoroughly removing unbound resting T cells which were more difficult to remove due to their small size and it was also quicker, allowing more careful kinetic analysis Both the aspiration and flicking wash protocols result in higher shear forces than techniques used in earlier studies with cells adhering to ICAM-1 in liposomes or planar membranes[2,49,50] These differences result in lower percent binding of unstimulated JY cells observed here Mab used in this study were TS2/4 (native LFA-1 α, IgG1)[51], TS1/18 (native LFA-1 β, IgG1)[51], TS1/22 (LFA-1 α, IgG1)[51], RR1/1 (ICAM-1, IgG1)[21], R6 5 (ICAM-1, IgG2a)[52], CL203 (ICAM-1, IgG1)[53], TS2/9 (LFA-3, IgG1)[51], OKT3 (CD3, IgG2a[54] Ortho Pharmaceuticals, Raritan, New Jersey) and Leu4 (CD3, IgG1)[55] (a gift from R Evans), 235 (ref. 29) and 38-1 (ref 25) (CD3 IgMs) were gifts from Drs S. M Fu and J. Ledbetter, respectively. Anti-CD6 IgM[56] and anti-CD6 IgG2a (JOR-T1, Dr Amador, Stockholm) were obtained from the T-cell panel of the Fourth International Leukocyte Workshop.

to understanding regulation of this adhesion mechanism as it suggests a requirement for membrane fluidity or metabolic energy. As previously demonstrated, binding of JY cells to ICAM-1 was abolished at 4 °C (ref. 2); absence of adhesion was also observed when cells were pretreated with PMA for 30 min at 37 °C before testing adhesion at 4 °C (Fig. 1*c*). Dose-dependent adhesion of JY cells to purified LFA-1 was observed at both 37 °C and 4 °C, although binding at 4 °C was less efficient (Fig. 1*d*). The temperature effect on adhesion to purified ICAM-1 and LFA-1 also shows sidedness, therefore, with binding through cell-surface LFA-1 showing greater sensitivity than adhesion through cell-surface ICAMs.

Definitive evidence for LFA-1/ICAM-1 interaction was obtained by showing that purified LFA-1 protein micelles bind to ICAM-1 on plastic (Fig. 2). Specificity was demonstrated by lack of binding to purified LFA-3, inhibition with EDTA, and inhibition with anti-LFA-1 (TS1/22) and anti-ICAM-1 (RR1/1) monoclonal antibodies, which block cell-cell adhesion. Other antibodies that bind equally well to LFA-1 (TS2/4) or ICAM-1 (CL203) but do not block cell-cell adhesion had no effect. Also, identical results were obtained at 4 °C and 37 °C and thus binding of the purified molecules to each other is not temperature-dependent. Temperature therefore seems to be important for cellular processes that affect the avidity of LFA-1, but not for the function of cell-surface ICAMs, purified LFA-1 or purified ICAM-1.

TCR regulation of LFA-1 avidity

To determine whether regulation of the avidity of LFA-1 was physiologically relevant to antigen-specific T lymphocyte cell-cell interactions, we tested whether it was stimulated by TCR ligation. TCR stimulation triggers phosphatidylinositol turnover and elevates cytoplasmic Ca^{2+} (ref. 23). We studied resting T lymphocytes, rather than cloned T-cell lines, as the latter are already activated by antigen and by maintenance in culture and may be difficult to obtain as a homogeneous resting population. Because resting peripheral blood T cells vary in TCR specificity, bearing different $\alpha\beta$ or $\gamma\delta$ TCR subunits quantitatively associated with the invariant CD3 subunits, an effective way of stimulating them is with a monoclonal antibody against the CD3 component of the TCR complex. Resting T cells were incubated with anti-CD3, washed, and then incubated with a cross-linking anti-IgG, which is required to stimulate hydrolysis of phosphatidyl inositol and Ca^{2+} mobilization[24,25]. Anti-CD3 IgG alone has no effect on T-cell adhesion. Addition of anti-IgG, however, stimulated a significant increase in T-cell adhesion to ICAM-1 substrates, even more than with PMA (Fig. 1*e*). By contrast, there was no effect on adhesion to LFA-1 substrates (Fig. 1*f*). The CD6 antigen, present on T cells in similar amounts as the TCR, was used as a control for nonspecific effects. Cross-linking with an anti-CD6 IgG and anti-IgG did not result in an increase in adhesion (see Fig. 3*a*). The cross-linking anti-IgG could be intact IgG or Fab'_2 (not shown). The TCR-stimulated adhesion to purified ICAM-1 was completely blocked by monoclonal antibodies against LFA-1 α and β subunits and ICAM-1, which have previously been shown to block cell-cell adhesion (Table 1). Antibody TS2/4, which binds to LFA-1 but shows little inhibition of CTL killing[26], and anti-CD2 antibody, however, were not inhibitory.

A remarkable feature of T-lymphocyte interactions with other cells is the rapid progression from strong adhesion to de-adhesion. If the high-avidity state of LFA-1 were reversible, it could provide a mechanism for the unexplained phenomenon of adhesion and de-adhesion cycles. To address this question, we examined the kinetics of TCR-stimulated changes in the LFA-1 avidity state. Remarkably, the high-avidity state of LFA-1 stimulated by TCR cross-linking with anti-CD3 IgG and anti-IgG peaked at 10 min, with complete return to the low-avidity state by 30 min (Fig. 3*a*). By contrast, PMA-stimulated adhesion was maximal at 10 min and remained elevated for at least one hour. Purified T cells show a bimodal expression of LFA-1, as previously reported[27,28], with the two populations differing 2.5-fold in the number of LFA-1 binding sites per cell (Fig. 4). There was no significant change in LFA-1 expression on T cells pretreated with anti-CD3 IgG at 5 or 30 min after addition of anti-IgG. Thus, quantitative changes in LFA-1 surface expression are not involved in regulating either the induced binding at 5 min, or the decreased binding seen at 30 min. Also, addition of PMA to resting T cells that were stimulated by TCR cross-linking for 30 min restored high levels of adhesion within

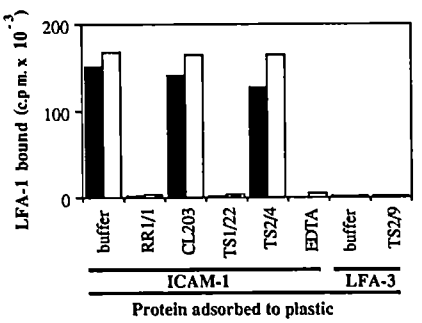

FIG. 2 Binding of LFA-1 protein micelles to ICAM-1 coated plastic. Binding was performed in the presence of the indicated additions at 4 °C (solid bars) or 37 °C (open bars).

METHODS. LFA-1 micelles were prepared by concentrating 2 ml fractions in 1% OG to 50 µl, resuspending in PBS and repeating the concentration step twice to remove residual detergent[57]. Protein concentration could then be determined by Coomassie blue dye binding[57]. LFA-1 micelles were iodinated with Iodogen (Pierce, Rockford, Illinois) to a specific activity of 10 µCi µg^{-1} (ref. 57). ^{125}I-labelled LFA-1 micelles (1 µg ml^{-1}) were incubated in microwells with 50 fmol ICAM-1 per well in 50 µl final volume of Hanks balanced salt solution, 10 mM HEPES, 2 mM $MgCl_2$. LFA-3 (ref 57) and ICAM-1 were adsorbed to plastic as in Fig. 1. Wells were preincubated with purified antibody at 100 µg ml^{-1} prior to adding LFA-1. After 2 h at 37 °C or 4 °C the wells were washed 6 times with assay media, bound LFA-1 was released with 0.1 M NaOH and subjected to gamma particle counting. Data are representative of two experiments. Monoclonal antibodies, as described in Fig. 1.

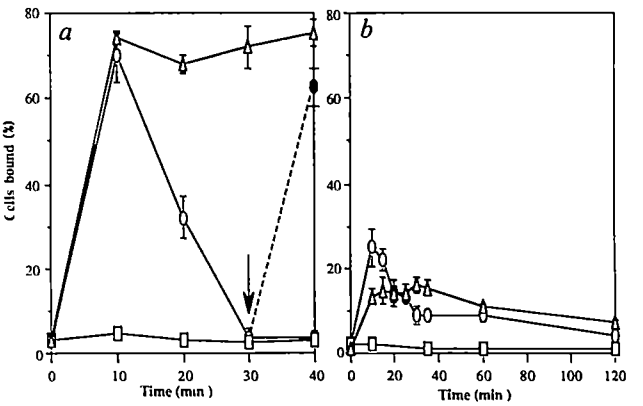

FIG. 3 Kinetics of TCR-stimulated increase in LFA-1 avidity. *a*, Resting T cells were treated with 50 ng ml^{-1} PMA (open triangles) or monoclonal antibody pretreated resting T cells were treated with 1 µg ml^{-1} goat anti-mouse IgG for varying time in suspension before transfer into wells and centrifugation onto an ICAM-1 coated surface. Pretreatment was with 1:500 anti-Leu4/CD3 ascites (open circles) or 1:500 JOR-T1 anti-CD6 ascites (open squares). In one case (arrow) T cells treated with anti-CD3 plus anti-IgG for 30 min at 37 °C were added to wells containing a final concentration of 50 ng ml^{-1} PMA (filled circle). Data is representative of 4 experiments. *b*, as in *a*, except resting T cells were treated with 235 anti-CD3 IgM at 10 µg ml^{-1} (open circles) or 1 µg ml^{-1} (open triangles) or anti-CD6 IgM at 1:500 ascites (open squares). CD6 staining was equivalent to 44% saturation with anti-CD3 monoclonal antibody. These data are representative of two experiments. The indicated time includes the 5 min centrifugation period.

10 min (Fig. 3*a*). This demonstrates that LFA-1 and the adhesion-promoting machinery are still functionally intact after the avidity decrease seen 30 min after TCR cross-linking. In addition, the experimental demonstration of 1.5 cycles of LFA-1 avidity regulation within 40 min indicates that the mechanism is truly capable of cycling, and in a rapid manner. Increased adhesion was also stimulated by anti-CD3 IgM without any need for further cross-linking (Fig. 3*b*), which is consistent with the ability of this anti-CD3 IgM to induce Ca^{2+} flux and phosphatidylinositol turnover in resting T cells[25,29]. The kinetics of the IgM-stimulated adhesion were concentration-dependent. With 10 μg ml^{-1} anti-CD3 IgM (80% saturation after 30 min at 4 °C, as determined by immunofluorescence flow cytometry), a distinct peak in adhesion to ICAM-1 at 10 min was obtained, which then decreased gradually over 2 h. Absence of an early peak with an even more sustained increase, maximal at 30 min, was obtained with 1 μg ml^{-1} anti-CD3 IgM (30% saturation after 30 min at 4 °C). No increase in adhesion was seen after addition of anti-CD6 IgM. Stimulation through TCR induces an increase in LFA-1 avidity, therefore, with kinetics dependent upon the degree of cross-linking.

Does the TCR communicate directly with LFA-1, or is it linked to LFA-1 through signalling pathways? Treatment of T cells with the cell-permeable cAMP analogue, dibutyryl cAMP[30–32], before TCR cross-linking or PMA addition, strongly inhibited TCR-stimulated adhesion to ICAM-1 substrates but had no effect on PMA-stimulated adhesion (Fig. 1*e*; Fig. 5). Similar decreases in adhesion triggered by both anti-CD3 IgG plus anti-IgG and anti-CD3 IgM were observed with dibutyryl cAMP (50% of maximal inhibition was achieved at ~1 mM) or the adenylyl cyclase activator forskolin (25 μM) plus the phosphodiesterase inhibitor isobutyl methyl xanthine (IBMX) (0.5 mM) (Fig. 5). These agents were used over ranges previously used to inhibit TCR signalling and were clearly not toxic, as PMA-stimulated adhesion was not decreased (Fig. 1*e*, Fig. 5). Butyrate (5 mM), a control for effects of butyrate released by degradation of dibutyryl cAMP, had no effects on unstimulated, or on cPMA- or TCR-stimulated adhesion to ICAM-1 (data not shown). The protein kinase C inhibitor, staurosporine (5 μg ml^{-1})[33], completely blocked the PMA-stimulated increase in LFA-1 avidity (Fig. 5), but, surprisingly, it only partially blocked TCR-stimulated adhesion. This illustrates either that protein kinase C can feed into the same pathway as the TCR, but is not a direct intermediate in TCR-stimulated signalling, or that the TCR can stimulate some additional mechanisms. Low concentrations of staurosporine (0.01–0.1 ug ml^{-1}) induced a small (2–5 fold) but significant increase in resting T-cell binding to ICAM-1, indicating that staurosporine may inhibit kinases that have an inhibitory effect on LFA-1 avidity (data not shown). The dramatic and opposite effects of PMA and cAMP, which activate protein kinases C and A, respectively, suggest that LFA-1 avidity is regulated by intracellular signalling pathways. These results support the notion that intracellular second messengers connect the TCR and LFA-1, and the concept that LFA-1 can transduce signals from the cytoplasm to the extracellular environment, an example of 'inside-out signalling'.

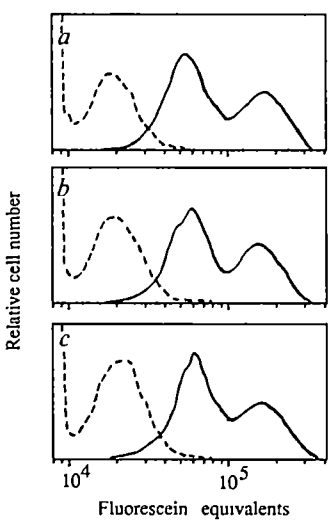

FIG 4 Expression of LFA-1 on TCR-stimulated resting T cells. Resting T cells were pretreated with OKT3 culture supernatant at 1:10 dilution (~80% saturation) for 30 min at 4 °C and washed. Anti-IgG2a (1 μg ml^{-1}) was either not added (*a*) or added for 5 min (*b*) or 30 min (*c*) at 37 °C before rapid cooling to 0 °C by addition of ice-cold media containing 0 025% NaN_3. Cells were then stained with fluorescein isothiocyanate (FITC) labelled LFA-1 monoclonal antibody (TS1/22) and analysed by immunofluorescence flow cytometry (FITC TS1/22 mAB, solid line; FITC control IgG1, dashed line). Only the relevant portion of the 3 log scale is shown.

TCR regulation of cell–cell adhesion

In interactions between cloned CTL lines and B-lymphoblastoid cell line (BLCL) target cells, both the CD2/LFA-3 and LFA-1/ICAM-1 pathways play a major part in adhesion[16,17]. We examined the effect of TCR cross-linking on the LFA-1/ICAM and CD2/LFA-3 dependent components of conjugate formation between resting T cells and BLCL (Fig. 6*a*, *b*). The BLCL used expressed high levels of ICAM-1 and LFA-3, but were LFA-1$^-$. We found that unstimulated fresh peripheral blood T cells showed much lower levels of conjugate formation (2–8%) (Fig. 6) than those previously published for cloned CTL (40–80%)[17]. The efficiency of conjugate formation was dramatically increased by TCR cross-linking and the increase in adhesion was completely blocked by anti-LFA-1 monoclonal antibody (Fig. 6*a*). A portion (10–25%) of the basal and stimulated adhesion was blocked by anti-LFA-3 antibody. The TCR-stimulated increase in T-cell adhesion seems to be due mainly to an increase in LFA-1 avidity, with no, or only a minor, contribution from CD2. TCR stimulation of LFA-1 avidity in cell-cell adhesion was transient and was blocked by preincubation of T cells with dibutyryl cAMP (Fig. 6*b*). Thus, the transient increase in LFA-1 avidity stimulated by the TCR is manifested both in binding to purified ICAM-1 and to ICAM-1$^+$ cells.

Role of LFA-1 avidity in immune response

Based on these findings, we propose the following model for cooperation between TCR and adhesion molecules to mediate antigen-specific recognition. LFA-1 on unactivated cells, such as resting T lymphocytes, is in a low avidity state which may be equivalent to the inactive state of LFA-1 on cells depleted of ATP with sodium azide and 2-deoxyglucose[1,15]. There may be some interaction between LFA-1 in the low avidity state and ICAM-1, but not enough to stabilize cell adhesion. In the absence of antigen, then, the equilibrium governing adherence of T lymphocytes to other cells favours free, mobile T lymphocytes, leading to efficient immune surveillance. On contact with cells bearing specific antigen, TCR ligation generates intracellular signals which lead to energy-dependent conversion of LFA-1 to a high-avidity state and LFA-1/ICAM-dependent adhesion is favoured. Antigen specificity is maintained because the input of energy to convert LFA-1 to the high-avidity stage, whether this energy is used to fuel protein phosphorylation, LFA-1 redistribution or some other mechanism, is controlled by the TCR. Cellular energy expended in converting LFA-1 to a high avidity state drives the adherence-nonadherence equilibrium towards stable adherence, and is analogous to the use of ATP to favour an otherwise energetically unfavourable reaction in intermediary metabolism. LFA-1 is an adhesion servomotor operated by the TCR. As TCR binding to peptide MHC does not have to stabilize cell-cell adhesion but instead triggers an adhesion amplification mechanism, this provides a mechanism for greatly increasing the sensitivity of T cells by lowering the number of TCR-ligand interactions required for antigen

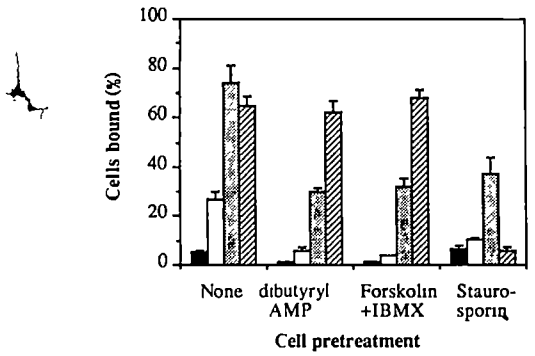

FIG. 5 Effect on LFA-1 avidity increase with pharmacologic agents that act on intracellular cAMP levels or protein kinases. Resting T cells were pretreated with the indicated agents for 15 min at 24 °C before stimulation and assayed for binding to ICAM-1 (1,600 sites μm^{-2}) as in Fig. 1. T cells were unstimulated (solid) or stimulated with anti-CD3 IgM (10 $\mu g\ ml^{-1}$) (open), anti-Leu4/CD3 IgG plus anti-IgG (1:500 Leu4 then 1 $\mu g\ ml^{-1}$ anti-IgG) (shaded), or PMA (50 $ng\ ml^{-1}$) (diagonal stripes). Dibutyryl cAMP (Calbiochem) was dissolved in media and was used at 2 mM. Forskolin (Calbiochem), IBMX (Sigma) and staurosporine (Boehringer) were dissolved in dimethyl sulphoxide (DMSO) and used at 25 μM (0.15% DMSO), 0.5 mM (0.25% DMSO) and 5 $\mu g\ ml^{-1}$ (0.5% DMSO), respectively DMSO at 0.6% had no effect on adhesion to ICAM-1 (data not shown). Data are representative of two experiments directly comparing these conditions and preliminary experiments to define optimal drug concentrations.

recognition. This view of adhesion strengthening is consistent with the recent observation in murine T-cell clones that LFA-1 and talin, a cytoskeletal protein which co-localizes with a number of integrins at sites of adhesion, redistribute to sites of interaction with antigen-bearing B cells, but not antigen-negative B cells[34]. It is intriguing that redistribution of LFA-1 and talin has been shown to be highly sensitive to low antigen concentrations, as would be expected of adhesion amplification.

The transience of the TCR-stimulated increase in LFA-1 avidity provides a mechanism for regulating the adhesion–de-adhesion cycle. We propose that the TCR triggers a cascade of protein phosphorylation or second messenger production such that an early step in the cascade leads to an increase in LFA-1 avidity and a later step lowers it. The kinetics of the LFA-1 avidity increase triggered by anti-CD3 IgG plus anti-IgG are in good agreement with the kinetics of CTL interaction with target cells. Highly active CTL bind to targets rapidly (0.2–2 min) and can deliver the lethal hit and disengage from the target within an additional 6 min[11,19], but this may be slower for some CTL–target combinations and immunization conditions[19]. It is of interest, therefore, that we have found that the kinetics of avidity regulation are influenced by the number of TCR engaged and the degree of cross-linking. Antigen density may, consequently, influence both the strength and kinetics of adhesion, presumably by affecting the kinetics of the signalling cascade. Duration of adhesion may also be influenced by the level of ICAM expression and whether ICAM-1 or ICAM-2 is the ligand. It is important to remember that as ICAM-1 is inducible by cytokines[1,35], T-cell stimulation could lead to induction of ICAM-1 on antigen-presenting cells, and secondarily alter the kinetics of T-cell interactions.

Although the mechanism of the regulation of LFA-1 avidity is unclear, a change in the conformation of the ICAM binding site or redistribution in the membrane seem most likely; either is compatible with the ability of a non-blocking anti-LFA-1 monoclonal antibody to stimulate LFA-1-dependent homotypic adhesion[36]. Another integrin, gpIIbIIIa, undergoes a well-documented increase in affinity. On unactivated platelets, gpIIbIIIa does not bind fibrinogen but upon activation binds soluble fibrinogen with a dissociation constant, K_d, of 29–45 μM (ref. 37), and no transience is reported. Neutrophil aggregation and binding to endothelium stimulated by chemoattractants is transient[38,39]; there is some evidence that the leukocyte integrin Mac-1 contributes to this[38,40], but estimates vary[40,41]. These phenomena are complicated by chemoattractant-stimulated increases in Mac-1 surface expression, the ability of multiple neutrophil receptors to bind both to endothelial cells and to fragments of C3, rapid shedding from the surface on neutrophil activation of another putative endothelium receptor, Mel-14 (ref. 42), and the generality of the effects on other neutrophil surface receptors that are not integrins[43]. Avidity increases for Mac-1, but not gpIIbIIIa, have been correlated with clustering of receptors in the plane of the membrane[44,45]; surprisingly, redistribution of Mac-1 and increased binding to iC3b are stimulated by phorbol esters but not by a chemoattractant[44], whereas neutrophil aggregation and binding to endothelium are stimulated by both[38,40]. The transience of the increase in avidity of neutrophil Mac-1/CR3 and of the non-integrin CR1 (refs 40, 43), by contrast to the stability of the increase in avidity of LFA-1, stimulated by PMA, suggests that separate mechanisms are involved.

We have defined a mechanism by which lymphocyte adhesion to other cells can be dynamically regulated. The type of inside-out signalling described here in which signals from the cytosol are transduced across the membrane to generate changes in extracellular functions such as adhesion could be of general importance in cell and developmental biology. In the model system studied here, TCR on the entire surface of the cell is ligated, whereas in physiological interactions TCR would be engaged only in the area of cell–cell contact and it would be possible that avidity enhancement would apply only to LFA-1 molecules in or recruited to this area of the cell. Integrins are thought to be important in cell migration as well as adhesion[7]. Spatial gradients of adhesion-molecule avidity on the cell surface could be generated by the same mechanisms as the temporal

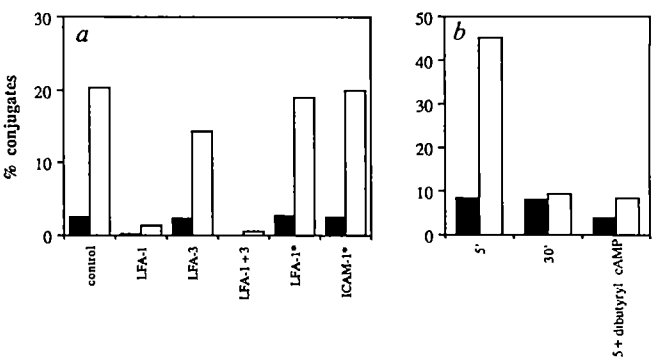

FIG. 6 Regulation of cell–cell adhesion by the TCR Resting T cells and the genetically LFA-1$^-$ BLCL BBN from patient 1 (ref. 5) were labelled with sulphofluorescein diacetate and hydroethidine, respectively, and conjugates were enumerated by fluorescence flow cytometry[17]. *a*, The resting T cells and BLCL were allowed to co-sediment for 1 h at 4 °C without (solid bars) or with (open bars) OKT3 anti-CD3 monoclonal antibody pretreatment and anti-mouse IgG2a and in the presence of the indicated antibody at 50 $\mu g\ ml^{-1}$. Binding, non-function blocking antibodies are asterisked. LFA-1, LFA-3, LFA-1* and ICAM-1* were TS1/22, TS2/9, TS2/4 and CL203, respectively, and are IgG1, so only OKT3 was crosslinked, as described in Table 1. The pellet was incubated at 37 °C for 5 min and analysed. *b*, Resting T cells were pretreated with OKT3 anti-monoclonal antibody and incubated without or with anti-IgG for 5 or 30 min as indicated (5′ or 30′) and then combined with BLCL and centrifuged at 20g for 5 min at 24 °C, incubated for 5 min at 37 °C and analysed. T cells were pretreated without or with 1 mM dibutyryl cAMP for 15 min at 24 °C before incubation with anti-IgG. METHODS. Cell purification was carried out as in Fig. 1. Labelling of cells was done as described[17]. Resting T cells were combined with BLCL at a 1:2 ratio (5×10^6 cells ml^{-1} total) in 50 μl of assay media. Before analysis the cell pellets were dispersed by adding 0.4 ml balanced salt solution with 1 mM $MgCl_2$ and vortexing for 5 s. Similar results were obtained with a more gentle resuspension.

gradient described here. In models of active cell translocation, it is generally appreciated that a mechanism for de-adhesion is required at the trailing edge of the cell[46,47]. A gradient of integrin avidity from high at the leading edge of a cell to low at the trailing edge could provide a mechanism for de-adhesion at the trailing edge and differential adhesiveness at the leading and trailing edges could drive cell migration. This would be analogous to haptotaxis, the ability of gradients of substrate adhesiveness to promote directed migration of cells[48].

ACKNOWLEDGEMENTS. We thank Dr S. Marlin for sharing the technique for adsorbing ICAM-1 to plastic, E. Luther for flow cytometry analysis of conjugates, Dr S. Ferrone for monoclonal antibodies and Helen Hourihan and Deborah Wilkinson for manuscript preparation. This work was supported by a grant from the NIH.

The Oct-1 homoeodomain directs formation of a multiprotein–DNA complex with the HSV transactivator VP16

Seth Stern, Masafumi Tanaka & Winship Herr

Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724, USA

The herpes simplex virus transactivator VP16 participates in the formation of a multiprotein–DNA complex with the ubiquitous octamer-motif-binding factor Oct-1. Complex formation is dependent on specific amino acids in the Oct-1 homoeodomain which are in positions analogous to positive control mutations in helix 2 of the λ phage repressor helix-turn-helix motif, indicating that this structure is an ancient target for protein–protein interactions mediating transcriptional control.

PROTEIN–PROTEIN interactions are fundamental to transcriptional regulation in eukaryotic cells. Such interactions are involved both in formation of a pre-initiation complex between RNA polymerase II and general transcription factors[1,2], and in contacts between sequence-specific DNA-binding transcription factors and the promoter-proximal complex (reviewed in ref. 3). Nevertheless, despite the purification of many transcription factors, specific protein–protein interactions remain largely uncharacterized.

In prokaryotes, however, at least one important interaction between a sequence-specific DNA-binding transcription factor, the phage λ repressor, and RNA polymerase has been well characterized. The λ repressor can positively activate transcription from the promoter P_{RM}, which is the promoter of the gene for λ repressor itself[4]. Amino-acid substitutions in λ repressor that abolish positive regulation of transcription from P_{RM}, but which do not affect either operator binding or negative regulation, have been termed positive-control mutations or *pc* mutations. The *pc* mutations map to a solvent-exposed patch on the surface of the DNA-binding domain of the protein which probably directly contacts the RNA polymerase bound to the promoter[5,6].

In eukaryotes, viral transactivator proteins that do not bind to DNA directly but alter patterns of gene expression, provide model systems to study protein–protein interactions. One of these, the herpes simplex virus (HSV) transactivator VP16, also called Vmw65, VF65 and α-TIF, can form a multiprotein–DNA complex with one or more cellular factors, which include the ubiquitous octamer-motif-binding protein Oct-1 (also called

OTF-1, OBP100 and NFIII)[7-10]. Here we show that formation of this multiprotein–DNA complex is dependent on structural features of Oct-1 which are analogous to features of λ repressor that are involved in the interaction of the repressor with RNA polymerase.

VP16 and Oct-1

The HSV VP16 protein is a late gene product that is incorporated into the virion tegument and, on infection, activates expression of the HSV immediate early (IE) genes[11,12] by binding with Oct-1 to the DNA target sequence TAATGARAT (where R is an unspecified purine)[7-10,13,14]. The TAATGARAT target sequence is a degenerate octamer motif that can also bind to Oct-1 in the absence of VP16 (refs 15 and 16). Both Oct-1 and the closely related lymphoid-specific Oct-2 protein are POU homoeodomain-containing proteins related to the pituitary-specific transcription factor Pit-1/GHF-1 and the nematode *Caenorhabolitis elegans unc-86* gene product[17]. The POU proteins are characterized by an extended region of homology called the POU domain, which is responsible for their ability to bind to DNA[18] and includes a C-terminal homoeodomain and an N-terminal POU-specific region of 75 amino acids[17].

Unlike Oct-2, Oct-1 does not apparently activate transcription of most promoters that contain TATA boxes, as such promoters with synthetic octamer motifs are not active in HeLa cells in which Oct-1 is expressed (see refs 19 and 20, and refs therein). Expression of VP16, however, which itself contains an acidic activation domain[21] analogous to those of the yeast activators GAL4 and GCN4 (refs 22–24), activates the octamer motif in these otherwise inactive promoters in non-lymphoid cells[9,19]. These results indicate that VP16, by virtue of its acidic domain and its ability to form a complex with Oct-1, can reprogramme the transcriptional activity of Oct-1.

Here we show that the Oct-1 homoeodomain directs formation of the complex with VP16. Oct-2 fails to direct the formation of a similar complex[10] because the amino-acid sequence of the Oct-2 homoeodomain differs from that of the Oct-1 homoeodomain at seven out of sixty possible positions. Sequence comparisons[25-28] and a structural analysis[29] indicate that homoeodomains contain a tri-α-helical structure similar to the DNA-binding domains of λ- and 434 repressors[30,31]. When the Oct-1 and Oct-2 homoeodomains are modelled as a DNA-binding domain of λ repressor, the positions of most, if not all, of the seven residues which differ between Oct-1 and Oct-2 lie on the surface of the homoeodomain that faces away from the DNA. Changing the amino-acid residues in Oct-1 at three of these seven positions with those amino acids at the corresponding positions in Oct-2 is sufficient to disrupt the formation of the complex with VP16 without obviously affecting the DNA-binding activity of the protein. Two of these three positions are analogous to the positions of *pc* mutations in the helix-turn-helix motif of λ repressor.

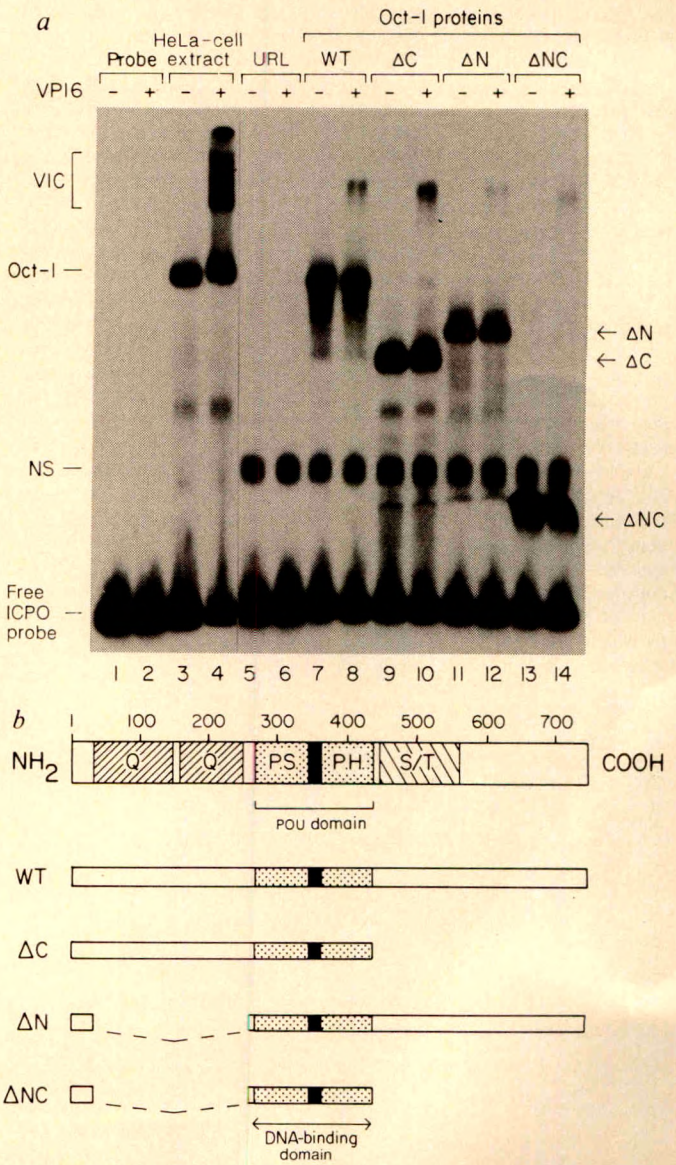

FIG. 1 Formation of a VP16-induced complex (VIC) by Oct-1 deletion mutants. *a*, Gel-retardation assay for VP16 complex formation by HeLa-cell extract or *in vitro* translated Oct-1 protein products and HSV virion lysate with the ICP0 probe. Seven different sets of reactions were performed in duplicate, either without (lanes 1, 3, 5, 7, 9, 11 and 13) or with (lanes 2, 4, 6, 8, 10, 12 and 14) HSV virion lysate. Probe alone (lanes 1, 2); HeLa-cell extract (lanes 3, 4); unprogrammed reticulocyte lysate (URL; (lanes 5, 6); wild-type (WT) Oct-1 (lanes 7, 8); (C-terminal deleted Oct-1 (ΔC) (lanes 9, 10); N-terminal deleted Oct-1 (ΔN) (lanes 11, 12); (C- and N-terminal deleted Oct-1 (ΔNC) (lanes 13, 14). The positions of the free ICP0 probe, a non-specific complex (NS), full-length Oct-1 (Oct-1), and (VICs) are shown on the left. The positions of the Oct-1-derived ΔC, ΔN and ΔNC complexes are indicated on the right. *b*, Schematic illustration of the Oct-1 proteins produced by *in vitro* translation of RNAs derived from pBSoct-1$^+$ and pBSoct-1$^+$ΔBH. The 743-amino-acid reading frame is boxed, and the glutamine-rich (Q), POU domain (PS, POU-specific region; PH, POU homoeodomain) and serine/threonine-rich (S/T) regions are indicated. Bottom, Truncations and internal deletions used to map the region responsible for VIC formation.

METHODS. The plasmids pBSoct-1$^+$ and pBSoct-1$^+$ΔBH were described previously[32]. Oct-1 constructs were linearized with *Hin*dIII or, in the case of C-terminal deletions, with *Pf*MI. Linearized DNAs (~3.5μg) were used to generate RNA transcripts with T7 RNA polymerase (Stratagene) according to the manufacturer's instructions. Nucleic acids were purified by phenol extraction and ethanol precipitation, and resuspended in 10 μl water. RNAs were translated in a rabbit reticulocyte lysate (Promega), according to the manufacturer's instructions with 1 or 2 μl RNA (~1 μg) per 25 μl reaction volume. The efficiency and quality of *in vitro* translation were monitored by SDS-PAGE of the ^{35}S-labelled products and equivalent amounts of Oct protein were used in each experiment. The buffer conditions for complex formation were as described[10]. Either 5 μg of HeLa cell nuclear extract or 1 μl programmed reticulocyte lysate were incubated alone or in the presence of ~0.06 μg HSV virion lysate containing VP16 (ref. 8) in a 12.5 μl reaction for 30 min at 30 °C. The probe, containing a TAATGARAT homology from the promoter of the *ICP0* gene of HSV, was prepared from the complementary oligonucleotides GATCCCGTGCATGCTAATGATATTCTTTGGG and GATCCCCAAAGAATATCATTAGCATGCACGG, which were treated with kinase, annealed, and cloned into the *Bam*HI site of plasmid pUC119. The probe was excised as an *Eco*RI–*Hin*dIII fragment, 3′ end-labelled using Klenow fragment and 800 Ci mmol^{-1} dNTPs, and gel-purified. A gel slice containing the probe was eluted into 200 μl TE (10 mM Tris-HCl, 1 mM EDTA, pH 8) and 1 μl (10–20,000 c.p.m.) was used in each reaction. After incubation, reactions were loaded directly onto 4%, 40:1 acrylamide:bisacrylamide gels in TBE (25 mM Tris-borate, 0.5 mM EDTA, pH 8.3) and electrophoresed at 12 V cm^{-1} for ~2 h. After electrophoresis the gels were fixed to remove unincorporated [^{35}S]methionine, dried and autoradiographed with two sheets of film to block the ^{35}S decay from the *in vitro* translated products.

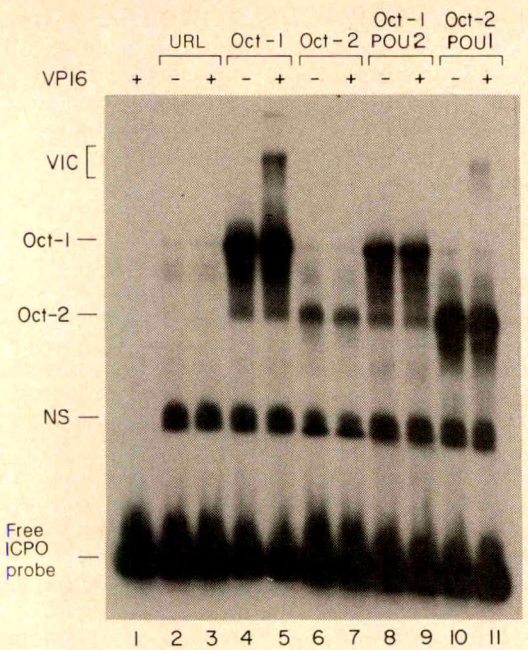

FIG. 2 VP16-induced complex formation by Oct proteins with exchanged POU domains. A gel retardation assay for VP16-induced complex formation by wild-type Oct-1 (lanes 4, 5), Oct-2 (lanes 6, 7), chimaeric Oct-1/POU2 (lanes 8, 9) and Oct-2/POU1 (lanes 10, 11) proteins is shown. Each protein was assayed without (lanes 2, 4, 6, 8, 10) and with (lanes 1, 3, 5, 7, 9, and 11) HSV virion lysate. Lane 1, HSV virion lysate alone; lanes 2 and 3, unprogrammed reticulocyte lysate (URL). The positions of Oct-1, Oct-2 and VP16-induced complexes are indicated on the left. Note that longer exposures of this gel did not reveal any VP16-induced complexes in lanes 7 and 9.
METHODS. The plasmids described here all derive from pBS M13$^+$ (Stratagene). Oct-1 was produced from pBSoct-1$^+$. The Oct-2, Oct-1/POU2 and Oct-1/POU1 proteins were produced from pBS$^{B\text{-}X}$-oct-2(2)2(3)2, pBS$^{B\text{-}X}$-oct-1(2)2(3)1, and pBS$^{B\text{-}X}$-oct-2(2)1(3)2 constructs, respectively. The numbers in parentheses denote silent *Xho*I (2) and *Sal*I (3) restriction sites in the N-terminal-LEQ and C-terminal-RRQ POU-domain encoding sequences, respectively, and the B-X- superscript indicates that the *Bam*HI and *Xba*I sites in the pBS M13$^+$ polylinker were destroyed (by digestion, end-repair and religation). These constructs all contain unique *Xba*I and *Bam*HI restriction sites immediately upstream of the initiation codon (TCTAGAATG), and immediately downstream of the stop codon (TGATGGATCC), respectively. All restriction sites were introduced by oligonucleotide-directed mutagenesis and will be described in detail elsewhere (M.T. and W.H., unpublished results). The *oct-2* initiation (pass-5.5) and termination (pass-3) codons are as previously described[35]. The *oct-1* initiation codon, the first AUG in the *oct-1* sequence, and stop codon are as described previously[32]. The POU domain sequences were exchanged by exchanging *oct-1* and oct-2 sequences between the *Xho*I and *Sal*I sites. To generate templates for transcription *in vitro* by T7 RNA polymerase, plasmids containing the initiation and termination codons for either *oct-1 or oct-2* parental constructs were linearized with *Hin*dIII and *Bam*HI, respectively.

The Oct-1 POU domain and VP16

To assay Oct-1 and VP16 complex formation we used the gel-retardation conditions and a TAATGARAT DNA element described previously[10]. This element was derived from the promoter of the ICP0 gene of HSV, also referred to as IE110K, IE gene 1 and α0, and contains imperfect overlapping octamer (ATGCAAAT) and TAATGARAT motifs (ATGCTAATGATAT). To form VP16-induced complexes, complementary DNAs corresponding to wild-type and mutant Oct-1 were transcribed and translated *in vitro*, and incubated with VP16 supplied by a HSV virion lysate. To prepare the lysate, HSV virions were collected from the growth medium of infected Vero cells and lysed by incubation with Nonidet P40 (NP40) as described by Preston *et al.*[8].

Figure 1*a* shows that incubation of the ICP0 TAATGARAT element (ICP0 probe; lane 1) with a control HeLa cell nuclear extract resulted in the formation of a single main Oct-1 complex (Oct-1; lane 3). As expected, there was no detectable complex formation when the virion lysate containing VP16 was incubated with the probe alone (lane 2), but further addition of HeLa cell nuclear extract resulted in the formation of both the Oct-1 complex and a series of more slowly migrating VP16-induced complexes (VIC; lane 4). Incubation of the probe with an unprogrammed reticulocyte lysate (lane 5) generated little specific Oct-1 complex, but a principal non-specific complex formed (NS); nevertheless, further addition of VP16 to the unprogrammed lysate had no obvious effect (lane 6). A lysate programmed with messenger RNA for Oct-1 (ref. 32), however, produced a major Oct-1 specific complex (lane 7), with faster-migrating minor complexes which probably resulted from internal initiation during *in vitro* translation. Further addition of the HSV virion lysate generated a slow migrating VP16-induced complex (lane 8). The VP16-induced complex can also be formed with VP16 translated *in vitro* (data not shown). In addition, as described previously[8] with Oct-1 derived from HeLa cells, the mobility of the VP16-induced complex is altered by the addition of the VP16-specific monoclonal antibody LP1 (ref. 33), indicating that VP16 is included in the VP16-induced complex (data not shown).

Comparison of lanes 3 and 4 with lanes 7 and 8 (Fig. 1*a*) shows that whereas the DNA-binding activities of Oct-1 from HeLa cell extract and Oct-1 translated *in vitro* are comparable, the VP16-induced complexes formed by the HeLa cell extract are both more numerous and complex. This difference has not so far been accounted for, but could in part have been attributable to the presence of additional HeLa cell proteins in the complex[10]. If such factors are required for complex formation, they are apparently also present in the rabbit reticulocyte lysate, although probably in limiting amounts–hence the relatively weak VP16-induced complex that is observed. In all the studies presented here, except those of Fig. 4, an Oct-1-depleted HeLa cell extract was not included to enhance formation of the VP16-induced complexes[10]. This is because the background level of

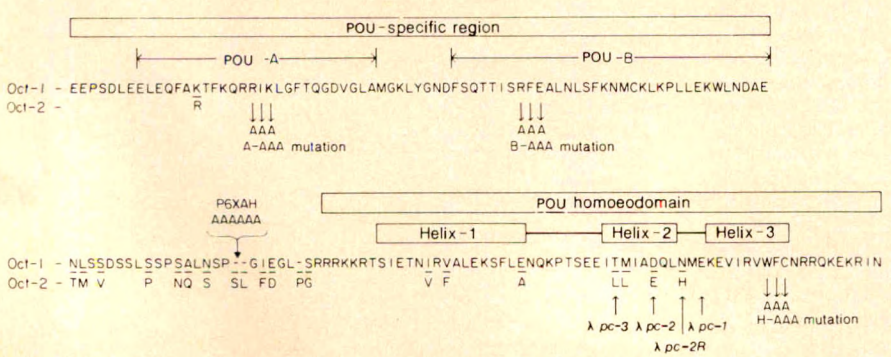

FIG. 3 Sequence comparison of the Oct-1 and Oct-2 POU domains. The locations of the POU-specific A and B regions and the POU homoeodomain are shown above the amino-acid sequence of Oct-1 (ref. 32). Oct-2 residues[35,43,44] that differ from Oct-1 are shown below the Oct-1 sequence, as are the positions of the A-AAA, B-BBB and H-AAA missense mutations, and the P6XAH insertion mutation. The three α-helices predicted to exist in the homoeodomain are indicated, as well as the positions of λ repressor *pc 1–3* mutations and the *pc-2* second site revertant *pc-2R*.

complex formation by unprogrammed reticulocyte lysate also increases, probably because of residual Oct-1 protein in the depleted extract. Regardless of the detailed composition of the complex, however, the results in Fig. 1*a* show that Oct-1 translated *in vitro* has the capacity to participate in a VP16-induced complex, and is therefore probably responsible for the OTF-1 activity described by Fletcher *et al*[34] and Gerster and Roeder[10].

Oct-1 can be divided into three regions: an N-terminal glutamine-rich region, a C-terminal serine/threonine-rich region, and a central POU domain composed of the POU-specific region and homoeodomain (Fig. 1*b*). We used previously characterized Oct-1 deletion mutants[32] to map the domain(s) of Oct-1 involved in complex formation with VP16. *In vitro* translated Oct-1 proteins with either their C-termini or N-termini deleted, or both (leaving a POU domain) were incubated with the ICP0 probe in the absence or presence of HSV virion lysate. All of these proteins bound to the ICP0 probe and produced complexes with mobilities that were approximately proportional to their relative molecular masses (Fig 1*a*; lanes 9, 11 and 13). Furthermore, as with full-length Oct-1, all of the deletion constructs formed a slowly migrating VP16-induced complex (lanes 10, 12 and 14). The mobility of the VP16-induced

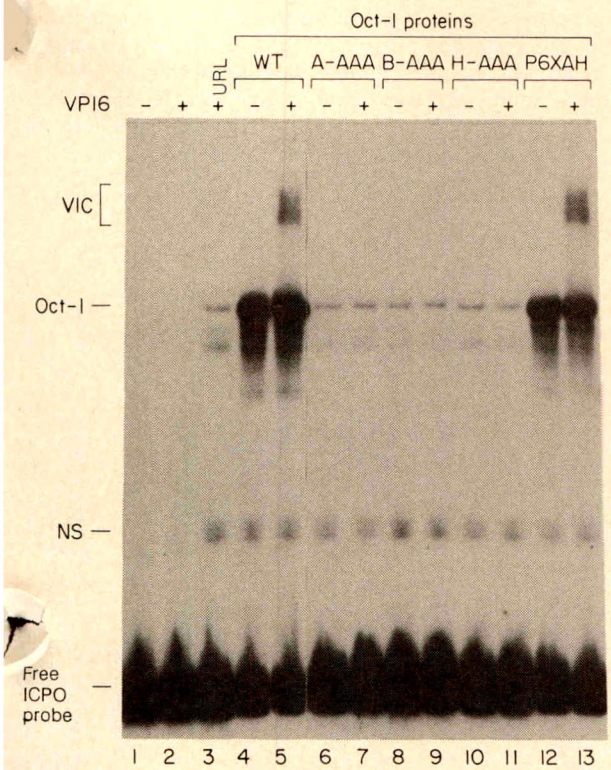

FIG. 4 VP16-induced complex (VIC) formation by Oct-1 POU domain mutant proteins. A gel retardation assay for VIC formation by wild-type Oct-1 (lanes 4, 5), the POU-specific A-AAA (lanes 6, 7), B-AAA (lanes 8, 9) and H-AAA (lanes 10, 11) triple amino-acid substitution mutants, and the Oct-1 insertion mutant with a six alanine insertion in the POU-linker (P6XAH; lanes 12, 13) is shown. Oct-1-depleted HeLa-cell extract was added to every reaction, and each protein was assayed without (lanes 1, 4, 6, 8, 10, and 12) and with (lanes 2, 3, 5, 7, 9, 11, and 13) HSV virion lysate. Lane 1, depleted extract only, lane 2, added VP16; lane 3, added VP16 and unprogrammed reticulocyte lysate (URL). Note that the addition of unprogrammed reticulocyte lysate to the Oct-1-depleted HeLa cell extract results in a small amount of residual Oct-1 binding activity and, in the presence of HSV virion lysate, a VIC is clearly evident after longer exposure of the film. The positions of Oct-1 complexes and VICs are shown on the left.

METHODS. Plasmids pBSoct-1$^+$A-AAA, pBSoct-1$^+$B-AAA, pBSoct-1$^+$H-AAA, and pBSoct-1$^+$P6XAH have been described[18]. HeLa cell nuclear extract was depleted for octamer-binding activity by repeated incubation with biotinylated octamer motif-containing DNA fragements linked to streptavidin-agarose beads. Depleted extract (1 μl) corresponding to 5 μg of proteins before depletion, was added to each reaction.

complexes shifts slightly as the size of the Oct-1 derivative changes, indicating that the different-length Oct-1 proteins are a part of the complex (compare lanes 12 and 14); the small magnitude of the shift, however, is consistent with other cellular proteins being present in the complex. The ability of the deleted Oct-1 proteins to complex with VP16 shows that the Oct-1 POU domain is sufficient to participate in, and direct the formation of, the protein–DNA complex that contains VP16. This result was unexpected, because Oct-2, which does not direct the formation of a complex with VP16 (ref. 10), contains a very similar POU domain.

The inability of Oct-2 to form a complex with VP16 could be intrinsic to its POU domain, or alternatively, the Oct-2 POU domain might be inhibited from forming a complex by the flanking N- and C-terminal regions of Oct-2. To distinguish between these two possibilities we constructed full-length chimaeric Oct-1 and Oct-2 proteins in which the POU domains were exchanged (Oct-1/POU2 and Oct-2/POU1), and assayed their capacity to form a complex with VP16 (Fig. 2). Consistent with the results with purified OTF-2 (ref. 10), incubation of the ICP0 probe with Oct-2 that was produced *in vitro* from the cloned *oct-2* gene[35] resulted in an Oct-2 complex, which migrates faster than the Oct-1 complex (lane 6), and addition of virion lysate did not result in the formation of a VP16-induced complex (lane 7). Under the gel retardation conditions described here, Oct-2 binds less effectively to the TAATGARAT probe than does Oct-1. Nevertheless, the results described below (for example, see Fig. 6) show that the inability of Oct-2 to complex with VP16 is not solely due to this weaker affinity of Oct-2 for the TAATGARAT probe. The chimaeric Oct-1/POU2 protein formed a complex with the probe with a mobility identical to that of the complex formed with the probe and wild-type Oct-1 (lane 8), but like Oct-2, did not form a complex with VP16 (lane 9). The chimaeric Oct-2/POU1 protein, however, produced an Oct-2-type complex with the probe (lane 10), but also formed a complex with VP16 (lane 11). Thus, the ability or inability to form a complex with VP16 is a property intrinsic to the POU domains of Oct-1 and Oct-2, respectively.

The Oct-1 homoeodomain and VP16

Figure 3 compares the sequences of the POU domains of Oct-1 and Oct-2, showing the positions of the POU-specific region and the homoeodomain. A 'linker' of 24 or 27 amino acids separates these two regions in Oct-1 and Oct-2, respectively. The POU-specific region can be subdivided into A and B segments, based largely on the position of three additional amino acids found in the POU domain of the *unc-86* gene product[36]. Oct-1 and Oct-2 differ at 1 out of 75, 12 out of 24, and 7 out of 60 positions in the POU-specific, linker and homoeodomain regions, respectively (Fig. 3).

We have previously used triple alanine substitutions in the POU-specific A region (A-AAA mutation) and B region (B-AAA mutation), and in the POU homoeodomain (H-AAA mutation), to show that these three regions are all necessary for effective DNA binding *in vitro*[18]. The poorly conserved linker region, however, is apparently not intimately involved in DNA binding because the six alanine insertion in this region (P6XAH mutation) (see Fig. 3) does not affect DNA-binding activity[18]. Here we used these four POU-domain mutations to investigate whether VP16 can functionally replace one of the mutated regions, or whether VP16 recognizes the Oct-1 linker, the POU domain region of greatest sequence divergence between Oct-1 and Oct-2. VP16 does not activate any latent DNA-binding activity in the A-AAA, B-AAA or H-AAA mutants (Fig. 4; lanes 6–11), and VP16-induced complex formation is unaffected by the linker insertion-mutation (compare lanes 5 and 13). These results indicate that VP16 cannot functionally replace the POU-specific region or the homoeodomain for DNA binding, and that the divergent linker region is relatively unimportant for VP16-induced complex formation.

To test the relative contributions of the POU-specific region and the homoeodomain to the formation of the VP16-induced complex, we used Oct-1 and Oct-2 proteins in which either their homoeodomain regions or POU-specific regions had been exchanged. When the Oct-1 POU-specific region and linker region were replaced by the corresponding Oct-2 sequences, there was no obvious effect on complex formation (Fig. 5*a*; compare lanes 2 and 4). This shows that VP16 does not distinguish between the Oct-1 and Oct-2 POU-specific sequences; but, because these two regions differ at only one position, it is nevertheless possible that the POU-specific region makes protein–protein contacts essential to form a VP16-induced complex. To test further the contribution of the POU-specific sequences to VP16-induced complex formation we made an Oct-1 protein containing most of the POU-specific region (the A and B regions) and all of the linker sequences from the other mammalian POU protein, Pit-1/GHF-1 (refs 37 and 38). Pit-1/GHF-1 binds to octamer-related sequences[39], but its POU-specific region and homoeodomain differ from those of Oct-1 at 39% and 43% of the positions, respectively; furthermore, the Pit-1/GHF-1 linker region is only 15 amino acids long and is totally divergent from that of Oct-1. Oct-1 that carried the POU-specific and linker sequences of Pit-1/GHF-1 (Oct-1/PS-P), however, could still direct complex formation with VP16, albeit at a reduced level, which may reflect a reduced affinity for the ICP0 probe (Fig. 5*a*; compare Oct-1 complexes in lanes 1 and 5). Although Oct-1/PS-P could still form a complex, an Oct-1 chimaera that carried nearly the entire Pit-1/GHF-1 POU domain (Oct-1/POU-P; see Fig. 5 legend) was unable to direct effective complex formation (lane 8). These results, together with those obtained with the Oct-1 POU domain mutants, indicate that the POU-specific and linker regions themselves do not contain determinants for the formation of a VP16-induced complex, but are nonetheless required because they are involved in DNA binding.

Figure 5*b* shows that the Oct-1 homoeodomain contains determinants for VP16-induced complex formation and is sufficient to activate the formation of a VP16-induced by Oct-2. When the Oct-2 homoeodomain was placed in Oct-1 (Oct-1/Ho-2), the VP16-induced complex disappeared (compare lanes 4 and 6), but when the Oct-1 homoeodomain was placed in Oct-2 (Oct-2/Ho-1), VP16-induced complex formation was activated (compare lanes 8 and 10), although at a level less than that with wild-type Oct-1 (compare lanes 4 and 10). This indicates that Oct-1 sequences outside the homoeodomain influence VP16-induced complex formation. These results show that the seven amino acids that differ between the Oct-1 and Oct-2 homoeodomains are sufficient to allow VP16 to discriminate between these two proteins.

Helix swap

Figure 3 shows the positions of the three predicted α-helices in the Oct-1 homoeodomain sequence, and Fig. 6*a* shows how they might exist in three dimensions should they be arranged like the λ repressor DNA-binding domain. The amino acids that differ between Oct-1 and Oct-2 are shown in both diagrams.

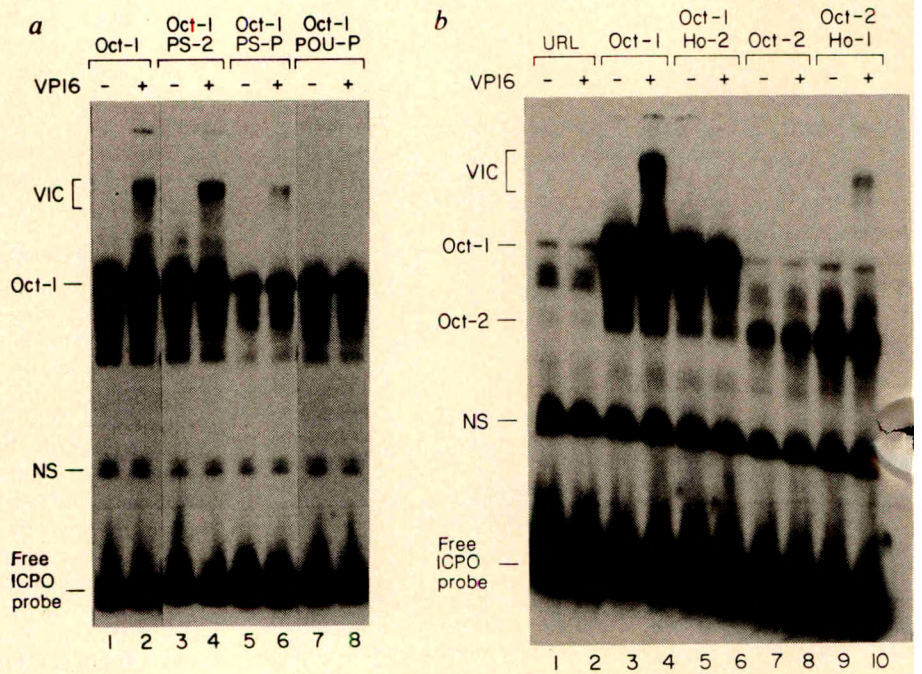

FIG. 5 VIC formation by Oct proteins with exchanged POU-specific regions or homoeodomains. *a*, Gel retardation assay of VIC formation by wild-type Oct-1 (lanes 1, 2), and Oct-1 carrying the Oct-2 POU-specific A and B regions (Oct-1/PS-2; lanes 3, 4), the Pit-1/GHF-1 POU-specific A and B regions (Oct-1/PS-P; lanes 5, 6) or Pit-1/GHF-1 POU domain sequences (Oct-1/POU-P; lanes 7, 8) Each protein was assayed without (lanes 1, 3, 5, 7) and with (lanes 2, 4, 6, 8) HSV virion lysate. *b*, Gel retardation assay for VP16-induced complex formation by wild-type Oct-1 (lanes 3, 4), Oct-1 carrying the Oct-2 homoeodomain (Oct-1/Ho-2; lanes 5, 6), wild-type Oct-2 (lanes 7, 8) and Oct-2 carrying the Oct-1 homoeodomain (Oct-2/Ho-1; lanes 9, 10). Each protein is assayed without (lanes 1, 3, 5, 7, and 9) and with (lanes 2, 4, 6, 8, 10) HSV virion lysate. Lanes 1 and 2 have unprogrammed reticulocyte lysate (URL) The positions of Oct-1 and Oct-2 complexes and VICs are shown on the left. Note that longer exposure of this gel did not reveal any VP16-induced complex in lanes 6 and 8.

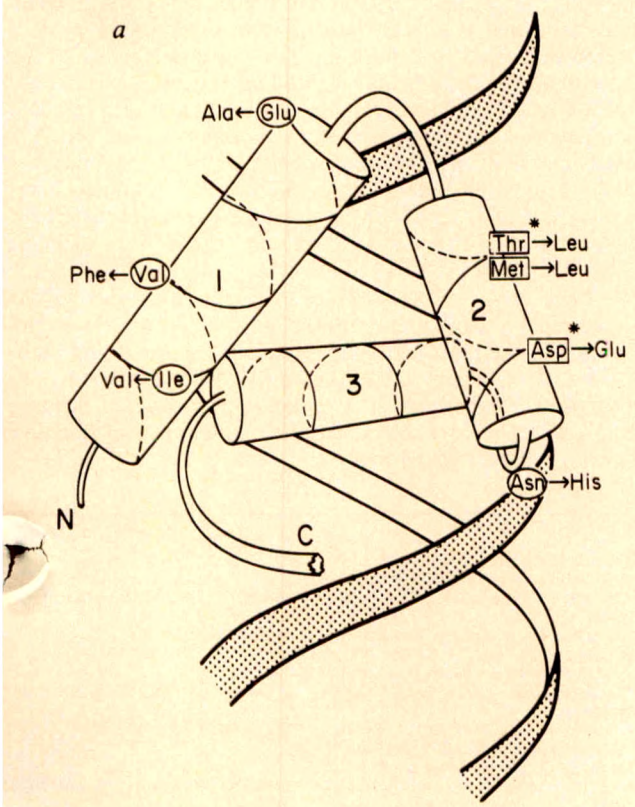

METHODS. The Pit-1/GHF-1 POU domain sequences[38] were cloned as follows. Complementary DNAs were produced from total GH3 pituitary cell RNA with random primers and the POU domain sequence was amplified by the polymerase chain reaction using Pit-1/GHF-1-specific primers that simultaneously created *Xho*I (with an overlapping *Sac*I site—GAGCTCGAG—as in the *oct-1* and *oct-2* genes) and *Sal*I sites at positions equivalent to the *Xho*I (2) and *Sal*I (3) sites in the *oct-1* gene described in Fig. 2 legend. In the pBSoct-1 parental construct used for the constructions described below (called pBS$^{\Delta}$oct-1), the polylinker *Bam*HI site is present and the sequences between the polylinker *Xba*I site and the *Xba*I site flanking the initiation codon have been deleted, but the 3′ termination codon *Bam*HI site remains, as described in Fig. 2 legend. The Pit-1/GHF-1 POU domain sequences between the engineered *Xho*I and *Sal*I sites were transferred to the pBS$^{\Delta}$oct-1(2)1(3)1 construct to create pBS$^{\Delta}$oct-1(2)P(3)1 (Oct-1/POU-P). In this construct the *Pit-1/GHF-1* POU domain sequences 5′ of the POU-specific A region (coding for 13 amino acids) and 3′ of the *Sal*I site in the homoeobox (coding for 7 amino acids with three differences between Oct-1 and Pit-1/GHF-1) derive from the *oct-1* sequence. To exchange POU-specific regions and POU homoeoboxes a silent *Nar*I restriction site was introduced in the sequences encoding the N-terminal of the homoeodomain (RRR sequence in *oct-1* and *oct-2*, and RKR sequence in *oct-1/POU-P*) in pBS$^{\Delta}$oct-1(2)1(3)1, pBS$^{B\text{-}X}$oct-2(2)2(3)2 and pBS$^{\Delta}$oct-1(2)P(3)1 by oligonucleotide-directed mutagenesis. The wild-type sequences were mutated to CGGCGCCGG (*oct-1*), CGGCGCCGC (*oct-2*) AGGCGCCGG (*Pit-1/GHF-1*) (the mutations are underlined) creating pBS$^{\Delta}$oct-1(2)1(N)1(3)1, pBS$^{B\text{-}X}$oct-2(2)2(N)2(3)2, and pBS$^{\Delta}$oct-1(2)P(N)P(3)1, respectively; the mutations are silent in *oct-1* and *oct-2*, whereas the *Pit-1/GHF-1* wild-type RKR sequence is altered to RRR. Oct-1/PS-2 [pBS$^{\Delta}$oct-1(2)2(N)1(3)1], Oct-1/PS-P [pBS$^{\Delta}$oct-1(2)P(N)1(3)1], Oct-1/Ho-2 [pBS$^{\Delta}$oct-1(2)1(N)2(3)1] and Oct-2/Ho-1 [pBS$^{B\text{-}X}$oct-2(2)2(N)1(3)2] were all constructed by transferring the appropriate *Xho*I/*Nar*I or *Nar*I/*Sal*I sequences between the parental *Nar*I mutant constructs. To generate RNAs for *in vitro* translation, the pBSoct-1 constructs (including *Pit-1/GHF-1* derivatives) and pBSoct-2 constructs were linearized with *Hin*dIII and *Bam*HI, respectively

Three amino-acid differences are found in helix-1, three in helix-2, and the seventh in the turn between helices-2 and -3 (Fig. 3). The position of three λ repressor *pc* mutations (*pc-1*, *pc-2* and *pc-3*), which interfere with the interaction of repressor and RNA polymerase but do not affect DNA-binding activity, are also shown (Fig. 3)[5,6], as is the position of a second site revertant of *pc-2*, *pc-2R* (ref. 5). Many or all of the seven positions that differ between Oct-1 and Oct-2 apparently lie on the surface of the homoeodomain (Fig. 6*a*). Furthermore, *pc-2* and *pc-3* map to positions that differ between Oct-1 and Oct-2 (see asterisks in Fig. 6*a*), indicating a parallel between Oct-1-directed VP16-complex formation and the interaction of λ repressor with RNA polymerase. To test the possibility of such a parallel, we exchanged the helices-2 of Oct-1 and Oct-2 by making three amino-acid substitutions in each protein.

Such a substitution (Oct-1/He_2-2) disrupts the formation of the VP16 complex (Fig. 6*b*; compare lanes 4 and 6); the longer exposure of the gel reveals that the formation of a residual complex between VP16 and the Oct-1/He_2-2 mutant is less than 10% of the complex formed between wild-type Oct-1 and VP16. But the reciprocal construct, in which the helix-2 of Oct-2 was replaced by the Oct-1 sequence (Oct-2/He_2-1), remained inactive (lane 10), showing that these three residues are necessary but not sufficient for complex formation. Although the Oct-1/He_2-2 mutant affects VP16-induced complex formation greatly, its DNA-binding activity seems to be identical to that of wild-type Oct-1 (compare the Oct-1 complexes in lanes 3 and 4 with those in lanes 5 and 6). Thus the interactions of Oct-1 with DNA and VP16 can apparently be dissociated. This result indicates that the reduction in VP16-induced complex formation by this chimaeric protein is attributable to a reduction in its capacity to direct complex formation with VP16, and is not attributable to a reduction in its affinity for the ICP0 probe.

The homoeodomain mediates positive control

Our results indicate that the Oct-1 homoeodomain is analogous to the helix-turn-helix motif of λ repressor in that it is simultaneously responsible for interaction with DNA and with other protein factors implicated in transcriptional control. Specifically, as with λ repressor *pc* mutations, mutations in the putative helix-2 of the Oct-1 homoeodomain can disrupt a protein–protein interaction that is important for transcriptional activation without an observable affect on DNA-binding activity. The

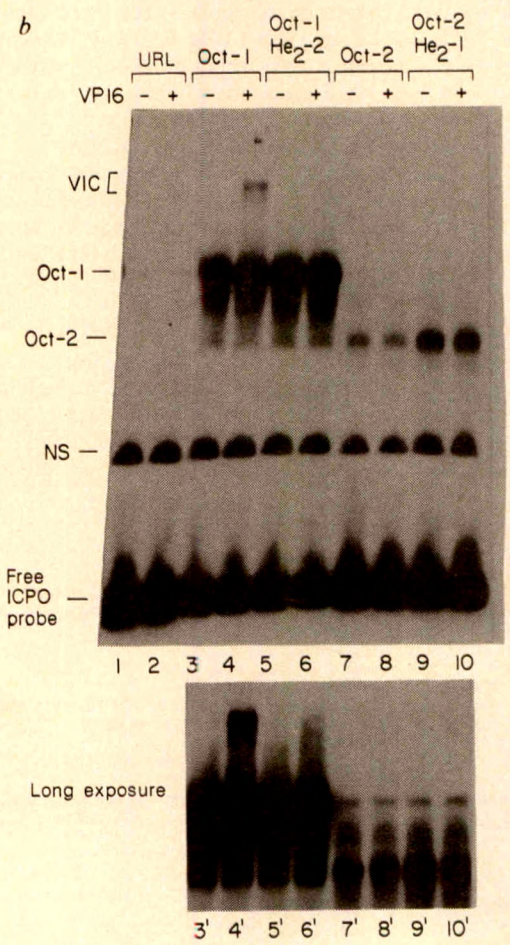

FIG. 6 Homoeodomain model and VP16-induced complex formation by Oct proteins with exchanged helix-2. *a*, Diagram of the tri-α-helical DNA-binding motif of λ repressor[30] and DNA (behind) as a model for the POU homoeodomain (S. Harrison, personal communication). The three α-helices are drawn as cylinders, with the α-carbon backbone indicated by solid (facing viewer) and dashed (hidden from viewer) lines. The seven amino-acid positions that differ between Oct-1 and Oct-2 are circled or boxed, with the Oct-1 residues shown inside and an arrow pointing to the Oct-2 residue. Boxed positions were exchanged in the helix-swap experiment, and asterisks indicate those positions in the homoeodomain that are analogous to λ repressor *pc-2 and pc-3* mutations. *b*, Gel retardation assay for VP16-induced complex formation by wild-type Oct-1 (lanes 3, 4), Oct-1 carrying Oct-2/helix-2 (Oct-1/He_2-2; lanes 5, 6), wild-type Oct-2 (lanes 7, 8) and Oct-2 carrying the Oct-1/helix-2 (Oct-2/He_2-1; lanes 9, 10). Each protein was assayed without (lanes 1, 3, 5, 7, and 9) and with (lanes 2, 4, 6, 8, and 10) HSV virion lysate. The positions of Oct-1 and Oct-2 complexes and VICs are shown on the left. Bottom, Longer exposure of the Oct complexes and VICs.

METHODS. Proteins with exchanged helices-2 were constructed by creating the mutant pBS$^{\Delta}$oct-1(2)1(3)1 and pBS$^{B\text{-}X}$-oct-2(2)2(3)2 constructs, pBS$^{\Delta}$oct-1(2)1$He_2$2(3)1 and pBS$^{B\text{-}X}$-oct-2(2)2$He_2$1(3)2, respectively, each with the three amino-acid changes in helix-2 as indicated in *a* by oligonucleotide-directed mutagenesis. Oligonucleotides containing the sequences CTTCTGATTGCTGAG and ACGATGATCGCCGATCA were used for Oct-1 and Oct-2, respectively, and the mutations are underlined.

inability of Oct-2/He_2-1 mutant to direct VP16 complex formation, however, shows that additional homoeodomain residues are required for activation of complex formation. The analogy to λ repressor indicates that the variable residue in the turn between helices-2 and -3 of Oct-1 and Oct-2 (see Fig. 3) may be critical for the interaction with VP16, because this is the position in λ repressor of the *pc-2* second site revertant, *pc-2R* (see Fig. 3), indicating that amino acids at this position may also be involved in positive control. Conversely, because variable residues in helix-1 of Oct-1 and Oct-2 may also be involved in complex formation, by analogy, similar positions in λ repressor may also be required for positive control.

Although the experiments described here show that the homoeodomain contains determinants that are sufficient to both inactivate and activate VP16-induced complex formation, they do not rule out the possibility that the POU-specific region also makes important protein-protein contacts with components of the VP16 complex. If this is the case, then this interaction probably involves residues in the POU-specific region that were not altered in the Oct-1 chimaera that contained Pit-1/GHF-1 POU-specific sequences (Fig. 5*a*), because this protein was still able to form the complex.

The amino-acid differences between Oct-1 and Oct-2 in helix-2 that affect formation of the VP16-induced complex follow no obvious pattern; there is a conservative aspartic to glutamic acid substitution, and two leucines replace the threonine and methionine residues found in Oct-1 (Fig. 6*a*). This is in contrast to the λ repressor *pc* mutations, which reduce the acidic character of the helix-2 region, an observation that indicated a parallel between positive control by λ repressor and the acidic activation domains of eukaryotic transcription factors[22,23]. VP16-mediated transcriptional activation also seems to involve an acidic activation domain, but in this case VP16 acts as an adaptor that effectively converts the Oct-1 homoeodomain to an acidic activation domain by a protein-protein association that itself no longer depends on acidic residues *per se*.

Implications for transcriptional regulation

Does the Oct-1 homoeodomain direct protein-protein interactions to regulate normal cellular transcription? Perhaps, to ensure a productive HSV infection, VP16 mimics a host-cell factor essential for cell viability, a cellular VP16 analogue. For example, a cellular VP16 analogue could be responsible for the octamer-dependent cell-cycle regulation of the histone H2B promoter[40]. Because it is not known whether VP16 itself, or instead a cellular factor, interacts directly with the Oct-1 homoeodomain, the exact role of a cellular VP16 analogue is unclear. If VP16 does not interact directly with the Oct-1 homoeodomain, then the results described here indicate that the cellular factor involved in complex formation represents a homoeodomain-binding protein. If VP16 does interact directly with the Oct-1 homoeodomain, it may be possible to design Oct-1 mutants that selectively interfere with VP16-induced complex formation without disrupting interactions with other cellular factors, thus serving to prevent HSV infection.

VP16 may interact with the Oct-1 DNA-binding domain because it must ensure transcription of the IE genes on HSV infection. Transcription of IE genes depends on the incorporation of Oct-1, which normally binds preferentially to the cellular octamer motif[15], in a VP16-induced complex that assembles on TAATGARAT sequence elements. VP16 may interact with the DNA-binding domain of Oct-1 to act as an allosteric effector that alters the DNA-binding specificity of Oct-1.

The ability of VP16 to discriminate between two proteins, Oct-1 and Oct-2, that recognize the same *cis*-acting element, shows how non-DNA-binding transcription factors can differentially influence transcription by two proteins that bind to the same DNA sequence. Like Oct-1 and Oct-2, *Drosophila* homoeodomain proteins also bind to similar sequences[41,42]. The results described here therefore indicate that protein-protein contacts that involve homoeodomains themselves could be important for developmental regulation. Indeed, the homoeodomain could have been selected during evolution to regulate development because its structure is amenable to protein-protein interactions. Consistent with this hypothesis, positions in helix-2 of homoeodomains in the products of the Antennapedia class of genes are hypervariable[27], a feature that could facilitate the discrimination among these very similar homoeodomains by a VP16-like factor.

We have shown protein-protein interactions involving the homoeodomain can alter patterns of gene expression. The utilization of the helix-turn-helix motif for DNA-binding functions and *trans*-acting activation functions, in a mammalian transcription factor and in λ repressor, provides a striking example of the conservation of protein structure and function between prokaryotes and man. □

CORE-DOMINATED radio sources associated with quasars are a manifestation of the most extreme form of activity in galactic nuclei. In general, the morphology of their inner radio structure is in the form of a jet detected on only one side of the core; the larger-scale radio emission is relatively symmetric[1]. Superluminal motion in some sources[2,3] has led to the suggestion that the ejection of radio-emitting material is relativistic and intrinsically two-sided. The apparent one-sidedness of the jets is then explained by relativistic aberration[4–6]. This persuasive interpretation has not escaped criticism: both physical[7] and statistical[8] arguments have been advanced in favour of one-sided ejection. However, our new optical observations of 3C120, which reveal the details of the interaction between the radio jet and the quiescent gas in the galaxy, offer significant kinematic evidence in favour of the relativistic-beaming hypothesis.

The radio source 3C120, at a redshift of 0.033 (ref. 9), is the nearest radio source with a one-sided jet[10,11] that exhibits superluminal motion[12]. Previous low-spatial-resolution spectroscopy[9,13] of the nebulosity surrounding 3C120 revealed underlying rotational motion in the gas, punctuated by large chaotic perturbations.

Recently a number of Seyfert galaxies have been found that have high-velocity narrow-line-region components that are spatially associated with their off-nuclear radio structure[14–16]. It is thought that these high-velocity components result from the interaction between ejected radio-emitting material and ambient gas in the surrounding galaxy[17–19]. In this process the gas experiences a strong shock, which both compresses and accelerates it[14,19]. The high-velocity emission-line components originate in cooling post-shock material that has been photoionized by ultraviolet radiation from the nucleus. To determine whether the complex motions observed in 3C120 could, as in the Seyferts, be of a systematic nature, we have re-investigated the velocity field at high spatial and spectral resolution. Here we show that close to the radio jet, far from being chaotic, the motions are a direct consequence of the interaction of the jet with the interstellar medium in the galaxy. This interaction creates an expanding cocoon of material around the jet which, in narrow-band images, appears as an emission-line counterpart to the radio jet[20].

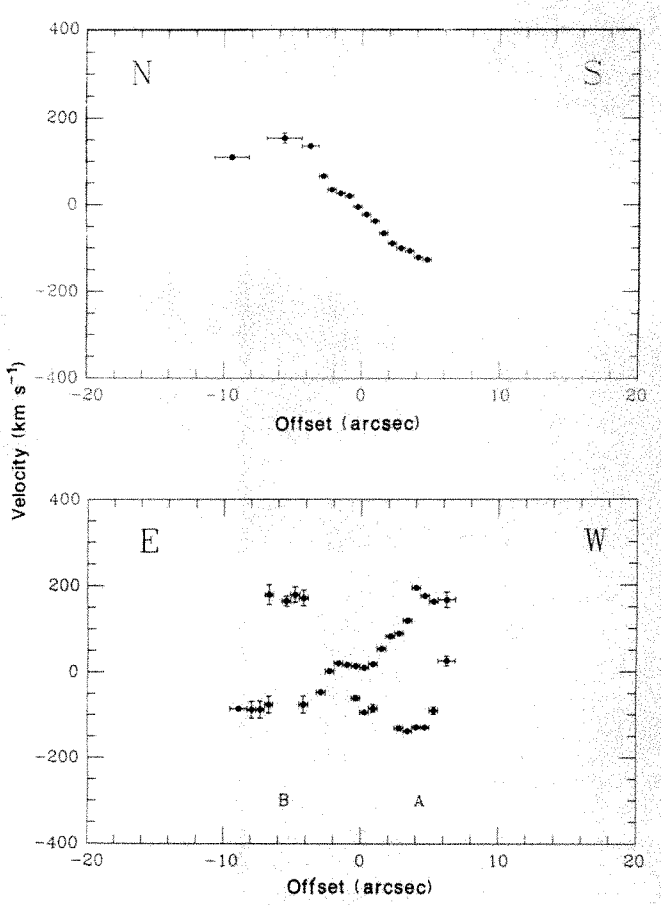

FIG. 2 The heliocentric radial velocities derived from [O III], $\lambda = 5{,}007$ Å for the spectra along PA = 359° (top) (passing through the nucleus), and along PA = 269° (bottom) (along the jet). The velocities shown are relative to 9,920 km s^{-1}, the systemic velocity of 3C120. Integration times of 10,000 and 16,886 s were used for PA = 359° and PA = 269° respectively, and the seeing was 1 arcsec. The position of the centre of the galaxy was determined by fitting a Cauchy function to the nuclear continuum.

We observed 3C120 at several epochs between 1985 December 21–25 and 1988 November 21–25, using the Intermediate Dispersion Spectrograph at the $f/15$ Cassegrain focus of the 2.5-m Isaac Newton Telescope and the Image Photon Counting System[21]. The slit positions discussed here are shown in Fig. 1, superimposed on a 1,666-MHz radio map of the inner jet structure of 3C120 obtained with the MERLIN[22] interferometer.

The variations of radial velocity along position angle 359°, the approximate major axis of the stellar light distribution[20], is

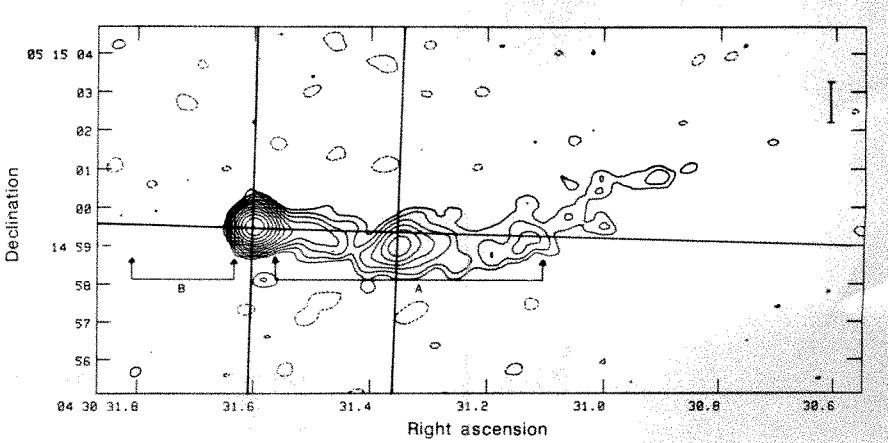

FIG. 1 A 1660-MHz map of 3C120 made with the MERLIN radio telescope. The contour levels are −2.0, −1.0, 1.0, 2.0, 4.0, 8.0, 16.0, 32.0, 64.0, 128.0, 256.0, 512.0, 1024.0 and 2048.0 mJy per beam and the peak flux density in the map is 2.06 Jy per beam. The slit positions discussed in the text are marked with solid lines and the FWHM of the seeing during the observations is shown by the vertical bar. All the spectra have a pixel size of 0.63 arcsec in the spatial direction and cover the spectral lines of Hβ, $\lambda = 4{,}861$ Å and [O III], $\lambda = 4{,}959$ Å, 5,007 Å at a resolution of 0.45 Å. A slit length of 78 arcsec and a width of 0.63 arcsec was used for all observations. The regions where two velocity components are observed are identified here and in subsequent figures by the letters A and B.

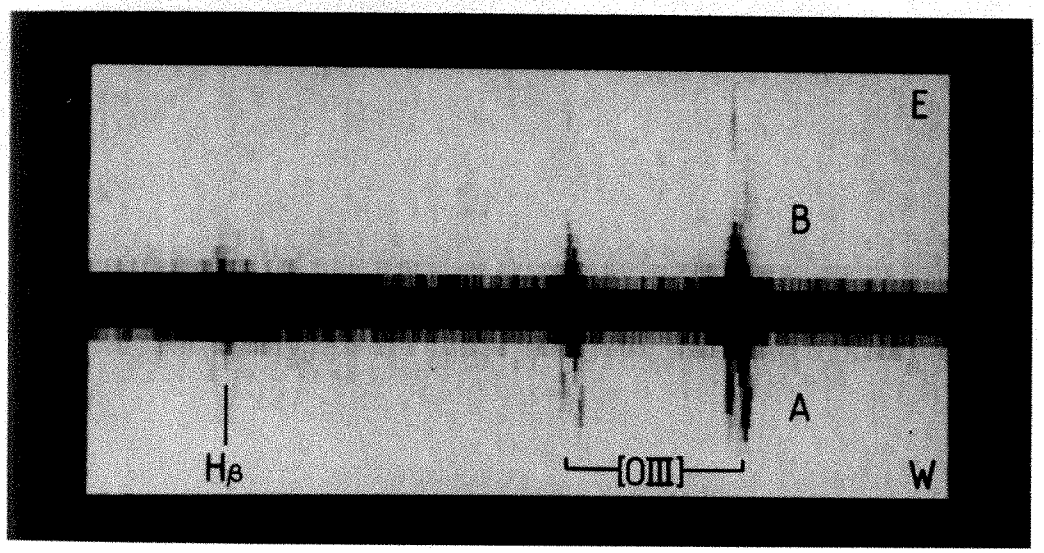

FIG. 3 A grey-scale image of the long-slit spectrum in PA = 269° (along the jet) resulting from a 12,000-s integration. The wavelength scale increases to the right and the Hβ and [O III] emission lines are identified. The orientation is as marked. The FWHM of both velocity components are very similar along the length of the jet and vary between 100 and 150 km s^{-1}. The pixels in this image do not correspond to true detector pixels.

shown in Fig. 2*a*. Over the central 8 arcsec the velocity varies approximately linearly with position, with an amplitude of ± 180 km s^{-1}, but at larger radii it flattens and eventually starts to turn over. Such behaviour is characteristic of the rotation curves of most disk galaxies[23]. This picture of 3C120 as a rotating disk galaxy is supported by a more detailed spectroscopic study which we will describe elsewhere.

The spectrum along the radio jet (position angle 269°) is shown in Fig. 3. To the west of the nucleus in region A, which is coincident with the radio jet, it is immediately apparent that the lines are split into two components. This splitting occurs continuously along the bright inner 6–7 arcsec of the radio jet. We measure the maximum separation of the blueshifted and redshifted components to be ~300 km s^{-1} (Fig. 2, bottom). At ~7 arcsec from the nucleus, the radio jet starts to bend to the north-west, and thus out of our slit. The [O III] emission stops abruptly at this point, suggesting that it is spatially associated with the jet. The observation perpendicular to the jet (Fig. 4) greatly strengthens this association, as it shows that the split-line region is localized to the jet and also that the surface brightness of [O III] is enhanced by a factor of 2–3 on the jet. The full width at half maximum (FWHM) of this emission peak is 3.2 ± 0.2 arcsec. Assuming that the Hubble constant H_0 is 75 km s^{-1} Mpc^{-1} then, at the distance of 3C120, 1 arcsec = 643 pc so the diameter of the split-line region is ~2 kpc.

The situation in 3C120 seems physically similar to that in the Seyfert galaxies, but with one subtle distinction: the median velocity of region A is within 30 km s^{-1} of the systemic velocity of the galaxy (9,920 km s^{-1}), suggesting that the split lines do not originate in material that has been ejected with the radio-emitting plasma, but arise instead because of the interaction, most probably lateral expansion, of the radio jet and the interstellar medium of the galaxy[17,18].

If we assume that the jet is in the plane of the sky, then the measured expansion velocity of 150 km s^{-1} implies that the dynamical timescale for the formation of the split-line region is $\sim 6 \times 10^6$ yr. This timescale is considerably shorter than the best estimates of the age of the radio lobes[10], and suggests that we are witnessing an expansion that is due to a recent outburst of the jet. The apparent width of the radio jet increases linearly with distance from the core[10]. Hence, for the jet to maintain its identity, the measured width-to-length ratio of ~0.1, coupled with this estimate for the expansion velocity, implies a bulk velocity for the jet material in excess of ~1,500 km s^{-1}. If, however, the jet makes an angle of 12–24° to the line of sight, as implied by the superluminal motion in the core[12], de-projection increases the lateral expansion velocity to ~350–700 km s^{-1}, leading to minimum ejection velocities in excess of 9,000–35,000 km s^{-1}. An independent limit on the angle of the jet to the line of sight of $\geq 10°$ is provided by the size of the emission-line region in conjunction with cooling-length arguments[19], as the shocked gas must have cooled to produce the observed emission peak.

The most intriguing aspect of our results is that velocity splitting, of comparable magnitude, is also seen to the east of the nucleus in region B, where no radio jet is detected. By analogy with region A, we believe that the natural explanation for the velocity structure of region B is that it is due to the interaction between a relativistic jet pointing away from us, and ambient gas in the galaxy. As the emission lines originate from material that is not moving relativistically, their intensity is not

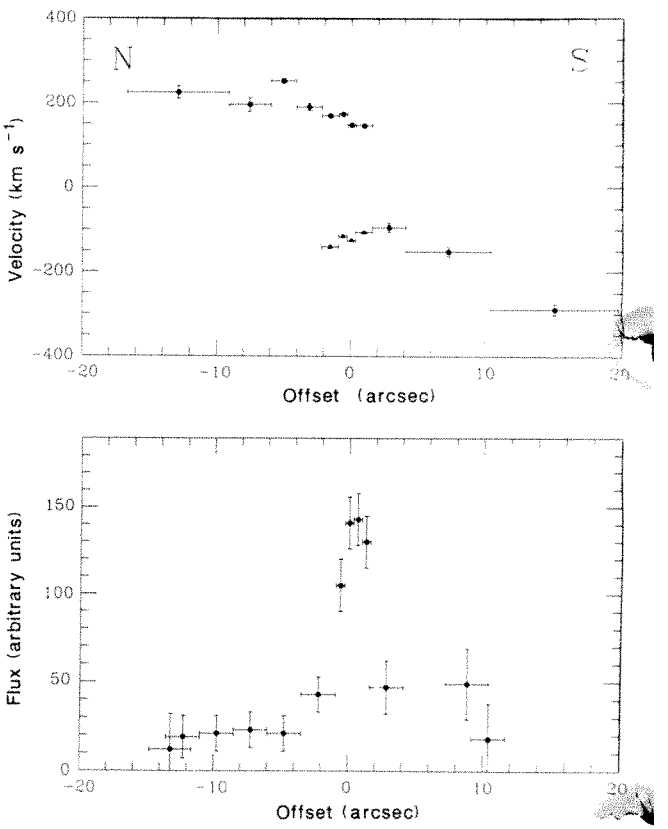

FIG. 4 The heliocentric radial velocities (top) and intensities (bottom) derived from the spectrum along PA = 359° and centred 4 arcsec west of the nucleus. Zero offset marks the centre of the radio jet. Where the emission lines are double, the intensities in the bottom figure are the sums of both components. The total integration time was 15,865 s and the seeing was 1.5 arcsec.

directly dependent on the orientation of the jet, whereas the intensity of the jet itself will be greatly diminished by relativistic aberration. As region B is further away from us its decreased surface brightness in [O III], compared with region A, would be the result of a combination of increased extinction and the fact that it has less cooled gas (the light travel time from region B makes it younger than region A by about 4×10^5 yr).

Can we rule out the alternative explanation that region B is a relic from a previous epoch when a single non-relativistic jet pointed in what is now the counter jet direction? A strong argument against this interpretation is that the expansion velocities on both sides of the nucleus are rather similar. To zero order, the stopping time of the shell is roughly the same as the acceleration time so this requires that region B was created no more than $\sim6\times10^6$ yr ago if it is not being driven by a jet now. Even assuming that the western jet is in the plane of the sky, its measured length, in conjunction with this timescale for its creation, would necessitate a single jet to be travelling at velocities close to the velocity of light.

It is clear from Fig. 4 (top) that the split-line region does not form a closed velocity loop as would be expected from a shell expanding in a uniform medium. However, hydrodynamic models[24] of expanding bubbles in a stratified medium, of the sort expected in disk galaxies, show that once the shell radius exceeds the scale height of the disk it will expand preferentially perpendicular to the plane of the disk because of the reduction in pressure. Commensurate with this 'puncturing' of the bubble, there will also be an increase in the cooling time and a decrease in the emission measure of the material forming the top and bottom of the shell. Consequently, only those parts of the shell that are 'snow-ploughing' through the disk will contribute to the observed velocity distribution. As the present radius of the shell in 3C120 is ~1 kpc, the velocity behaviour in Fig. 4 can be explained in this way provided that 3C120 is a disk galaxy with a typical scale height of ~0.5 kpc.

Observations with the Hubble Space Telescope would enable the kinematics of the gas to be investigated in the inner regions of the jet of 3C120 and in similar more distant objects. The most exciting prospect, however, would be to trace the splitting out to both radio lobes, thereby indicating a currently open fuel link with the central powerhouse. It would indeed be ironic if the controversy surrounding the origin of one-sided radio jets was resolved not by studying the jets themselves but by observing the interaction between the jets and their environment at optical wavelengths. □

Is the sub-millisecond pulsar strange?

Joshua A. Frieman & Angela V. Olinto

NASA/Fermilab Astrophysics Center, Fermi National Accelerator Laboratory, PO Box 500, Batavia, Illinois 60510, USA

THE interpretation of 1,968.629-Hz optical pulsations[1] from supernova 1987A as a rapidly rotating neutron star poses a challenge to models of nuclear matter. The simultaneous requirement that a star with angular velocity $\Omega_{SN}=1.237\times10^4\ s^{-1}$ be stable against non-axisymmetric perturbations and that the maximum mass of a non-rotating neutron star exceed 1.44 $M_\odot$ (the mass of the binary pulsar) seems to rule out all standard equations of state[2,3]. Three-flavour (up, down, and strange) quark matter, or 'strange matter', may be absolutely stable[4,5], that is, it may comprise the ground state of the hadrons. Neutron stars may become strange stars[6-8], which have a different equation of state and mass–radius relation from conventional neutron-star models. For a range of hadron parameters, the maximum rotation rate of secularly stable strange stars may exceed that of the half-millisecond pulsar and the non-rotating maximum mass M_{max} is greater than 1.52 $M_\odot$. The low-mass companion(s) to SN1987A, inferred from the periodic modulations of the optical signal, can be accounted for by stable strange-matter lump(s) ejected from the young strange star.

Once a stable seed of strange matter is formed inside a neutron star, it grows without bound and converts the star to strange matter[6-8]. Strange stars are thus fundamentally distinguished from neutron stars with quark cores by the assumption that quark matter is stable down to zero pressure. In the context of a bag-model calculation, this assumption has been shown to be plausible[4] for a range of values of the strange-quark mass m_s, the bag constant B (the difference in energy density between the perturbative vacuum and the true vacuum) and the strong coupling constant α_c. (In Fig. 1, we show contours of fixed energy per baryon number for strange matter, $E/A=899$ and 939 MeV, in the limit $\alpha_c=0$.) Although these three parameters have been estimated by fitting the bag model to the masses of light hadrons, these fits introduce additional variables, making it difficult to extract the values appropriate for bulk quark matter[4]. Also, the parameters m_s and α_c drop with increasing density, so fits made to low-density data may not be adequate for assessing strange-matter stability in neutron stars. (Furthermore, the bag model is probably a crude approximation to the behaviour of bulk quark matter; more appropriate might be a model in which B is a dynamical variable, for example an $SU(3)\times SU(3)$ sigma model (B. Lynn, private communication).) In exploring stellar models based on strange matter, we shall therefore impose only the self-consistency criterion, choosing parameters that lie in the estimated window of strange-matter stability, $E/A<939$ MeV. As one moves away from the stable strange-matter parameter region, neutron stars have shrinking quark cores, surrounded by growing envelopes of neutron matter. In this case, the transition to neutron matter typically takes place at or below nuclear density, $\rho_{tr}\leqslant\rho_{nuc}=2.8\times10^{14}\ g\ cm^{-3}$, if $E/A\leqslant950$–960 MeV (depending on the neutron equation of state). For the corresponding hadron parameter range, the envelope has a negligible role in the structure of the star and our results below carry through unchanged.

The equation of state (EOS) for strange matter can be written

$$p=\tfrac{1}{3}(\rho-4B)-\tfrac{1}{3}(\rho-B)\varepsilon. \qquad (1)$$

The function $\varepsilon(m_s(4B)^{-1/4}, \rho/4B)<0.14$ is a measure of the correction to the equation of state that accounts for the non-zero m_s and vanishes in the limits of $m_s=0$ (where strange (s), up (u) and down (d) quarks have equal abundances) and $m_s\simeq1.6(4B)^{1/4}$ (because the s-quark abundance is suppressed as m_s

approaches μ_s, the chemical potential). In calculating ε, we neglect $O(\alpha_c)$ corrections that result from quark interactions within the bag. These effects are small for the EOS, but they shift the window of strange-matter stability to lower values of B (ref. 4). We have constructed spherical general-relativistic star models using this equation of state. We note that for an EOS of the form of equation (1), the QCD energy scale $B^{1/4}$ can be scaled out of the Oppenheimer-Volkoff equation of hydrostatic equilibrium. Mass-radius sequences are thus characterized by the single dimensionless ratio $m_s/(4B)^{1/4}$. A number of consequences follow from this scale invariance. For example, for fixed $m_s/(4B)^{1/4}$, the ratio of the stellar radius to the Schwarzschild radius for maximum-mass models, $R_{max}/2GM_{max}$, is independent of B.

Parameters of the maximum-mass models are given in Table 1 in terms of a fiducial bag constant $B_0^{1/4} = 145$ MeV ($B_0 = 57$ MeV fm^{-3}). Because the mass scales as $M \sim B^{-1/2}$, the maximum mass reaches a lower bound at the edge of the strange-matter stability window, $E/A = 939$ MeV; there, $M_{max} > 1.52\,M_\odot$, with $R_{max} > 8.52$ km. By contrast with some soft equations of state, this is large enough to account for the observed mass[9] of PSR1913+16 and is consistent with other inferred binary masses; neutron-star mass observations to date place no constraints on the allowed parameter space.

The maximum rotation rates of neutron stars depend sensitively on the mass distribution and thereby on the equation of state. Generally, soft models are more centrally condensed, have smaller radii and maximum masses and can rotate faster than stiff models. Strange matter embodies elements of both soft and hard equations of state. For example, at the low-mass end, where gravity plays essentially no role in their structure, strange stars are approximately uniform-density spheres with $\rho \simeq 4B$ and $M \sim R^3$. Low-mass strange stars, and the outer regions of strange stars that are more massive, are much stiffer than all neutron-star models. In the central regions of strange stars near the maximum mass, however, $\rho_c \simeq 5(4B)$ and the equation of state gets very soft (relativistic Fermi gas).

Massive strange stars are thus hard on the outside and soft on the inside. The stiffness is reflected in the relative flatness of the density profile: for maximum-mass models, $\rho_c/\bar{\rho} = 2.1$–2.7, lower than or comparable to the stiffest neutron-star models. On the other hand, for large values of B, the maximum-mass strange stars have global features comparable to soft nuclear models For example, consider models along the contour of constant radius $R = 8.7$ km in Fig. 1. At $m_s = 0$, we find $M_{max} = 1.59\,M_\odot$, with average density $\bar{\rho} = 1.15 \times 10^{15}$ g cm^{-3} and moment of inertia $I = 1.15 \times 10^{45}$ g cm^2. As one moves up to $m_s/(4B)^{1/4} = 0.75$, these values drop by less than 3%, whereas the central density decreases from 3.09×10^{15} to 2.75×10^{15} (the density profile flattens). Of the models in the Arnett-Bowers collection[10], this is closest to EOS A, the Reid soft core[11]. Also, at $m_s = 0$, for the maximum-mass strange star, the pressure-averaged adiabatic index $\bar{\Gamma} = \bar{p}/(\bar{\rho} - 4B)$ is 2.3, which is moderately soft.

How fast can strange stars spin? A lower bound on the maximum rotation rate is given by the low-mass models with $m_s = 0$. Although low-mass strange stars are bound principally by the strong interactions, not gravity, their stability against rotationally induced fission into smaller fragments is determined by gravity because the gravitational energy increases when the star is deformed by rotation, but the nuclear binding energy does not. For $M < 0.5(B/B_0)^{-1/2} M_\odot$, the ratio of central to average density $\rho_c/\bar{\rho} < 1.06$, the pressure $p_c < 0.06\rho_c$, the averaged polytropic index $\bar{n} = (\bar{\Gamma} - 1)^{-1} < 0.1$, and the post-newtonian corrections to gravity are negligible. When they rotate these ultra-stiff low-mass stars are excellent approximations to newtonian Maclaurin spheroids (the Maclaurin approximation improves as the mass decreases). As the average density is bounded from below by $\bar{\rho} > 4B$, the maximum rotation rate, which is determined by the dynamical instability[12], is $\Omega_{dyn} = 0.67(\pi G\bar{\rho})^{1/2} > 6.22 \times 10^3 (B/B_0)^{1/2}$ s^{-1}. The non-axisymmetric secular $m = 2$ instability, driven by gravitational radiation reaction (GRR)[13], sets in at $\Omega_{sec} = 0.91\Omega_{dyn}$. Although there are also modes with $m > 2$ that become unstable at lower angular velocity, strange stars can rotate fast enough to account for the 1.6-ms pulsar.

More-massive strange stars can rotate faster because they have higher densities. For strange stars near the maximum mass, we estimate the maximum rotation speed using the results[2,3,14] for other equations of state. An absolute upper limit is set by the onset of equatorial (keplerian) mass shedding. For all the models considered in refs 2, 3, and 14, the keplerian limit of the maximum-mass star was found to lie in the range $\Omega_k = (0.76 \pm 0.04)(\pi G\bar{\rho}_s)^{1/2}$, where $\bar{\rho}_s$ is the average density of the spherical (non-rotating) maximum-mass model. To account for the apparent angular velocity of PSR1987A, $\Omega_k > 1.237 \times 10^4$ s^{-1}, the density must satisfy the constraint $\bar{\rho}_s > (1.12 - 1.37) \times 10^{15}$ g cm^{-3}. Maximum-mass strange stars with average density in this range correspond to the parameter region between the two dashed curves of Fig. 1. Thus, within the uncertainties, there is a range of hadronic parameters for which strange stars may rotate fast enough to account for the 0.5-ms pulsar. Clearly, a more accurate determination requires rapidly rotating strange-star models.

Although some conventional neutron-star models, such as those based on EOS A or F[2], also satisfy the constraint $\Omega_k > \Omega_{SN}$, they are secularly unstable to perturbations in the $m = 4$ or 5 mode[2,3,15–19]. Because these GRR-driven instabilities are damped by viscosity, the origin of the difficulty is the relatively low viscosity of hot young neutron matter. In this regard, strange matter offers two advantages. First, at equal temperature and density, the shear viscosity of strange matter[20] $\eta_s \approx 9.7 \times 10^{16} (\alpha_c/0.13)^{-3/2} (\rho/10^{15})^{5/3} (T/10^{10}\,\mathrm{K})^{-2}$ g cm^{-1} s^{-1}, is roughly an order of magnitude larger than that of nuclear matter[21], $\eta_{nuc} \approx 9.6 \times 10^{15} (\rho/10^{15})^{9/4} (T/10^{10}\,\mathrm{K})^{-2}$. Here, the strange-matter viscosity has been calculated to lowest order in α_c, assuming the magnetic field $B \lesssim 10^{10} (T/10^9\,\mathrm{K})^2$ G. (This is consistent with the observatonal upper bound on the field of SN1987A determined by the continued decline in bolometric luminosity.) Second, neutrino cooling in strange stars is significantly more efficient than the modified URCA process[22]. As a result, the core temperature of a two-year-old strange star is estimated to be $\sim 10^8$ K, as opposed to $\sim 10^9$ K for neutron stars. As the shear viscosity scales as T^{-2}, the present strange-star viscosity, $\bar{\nu} \simeq 6 \times 10^5$ cm^2 s^{-1}, is a factor $\sim 10^3$ larger than that for young neutron stars. Consequently, GRR-driven secular instabilities are more effectively damped in strange stars. Using the estimated viscous-damping timescale[15–17,19], we find that the $m = 3$ mode would limit the current angular velocity of the

Fiducial bag constant $B_0^{1/4} = 145$ MeV

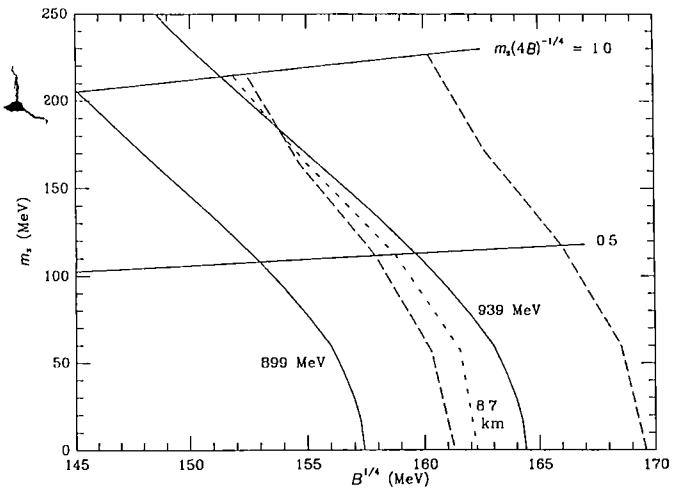

FIG. 1 The strange-matter parameter space Solid curves marked 899 and 939 MeV are contours of constant energy per baryon number for bulk strange matter (from ref. 4). Dot-dashed curve is the contour of constant radius $R = 8.7$ km for non-rotating maximum-mass models. The area between the dashed curves indicates the region within which the expected keplerian rotation speed $\Omega_k = \Omega_{SN1987A}$ Also shown are lines of constant $m_s/(4B)^{1/4} = 1.0$ and 0.5

putative strange pulsar. For this mode and for the viscosity above, the pulsar rapidly spins down if $\Omega \geq (0.98\text{–}0.99)\Omega_k$ (refs 16, 17, 23). Thus, the secular instability does not substantially narrow the possibilities for rapidly rotating strange stars. By contrast, a two-year-old neutron star is unstable, on a timescale shorter than the observed lower limit for SN1987A, if $\Omega \geq (0.92\text{–}094)\Omega_k$ (ref. 23). Also, at earlier times (and therefore higher temperatures), the bulk viscosity of strange matter can be quite large[24] (depending on m_s) and may have a role in stabilizing the secular modes.

The reported 8-hour modulation of the optical pulsar period has been interpreted as evidence for a Jupiter-mass companion to SN1987A (ref. 1). Unlike neutron stars, strange stars are bound by the strong force rather than gravity; they have no minimum stable mass Thus, planetary-mass strange-matter debris ejected in an asymmetric supernova collapse, or shed in a rapidly rotating post-collapse phase, would not disintegrate. Furthermore, strange-matter lumps have a density comparable to that of strange stars, so they can be ejected without being disrupted by tidal forces.

The SN1987A pulsar data also seems to have a second amplitude and phase modulation, with a period of ≈ 2 h. If this modulation is attributed to a second companion, it implies a Neptune-mass planet on a highly eccentric orbit with semi-major axis of about 6.5×10^5 km (J. Middleditch, personal communication). To survive tidal disruption, such a satellite must have a mean density $\bar{\rho} \geq 25$ g cm^{-3}. This is much higher than the density of any planet and the inferred mass is well below the lower mass limit for white dwarfs. Only a strange-matter lump seems to be consistent with this. An alternative explanation is modulation that arises from the precession of the pulsar; this hypothesis could be tested with further data. If precession is ruled out, the case for strange matter would be compelling. □

Tropospheric lifetimes of halogenated anaesthetics

CONCERN has been expressed over the use of the halogenated anaesthetics halothane ($CF_3CClBrH$), enflurane (CF_2HOCF_2CFClH) and isoflurane ($CF_2HOCHClCF_3$) because of their potential for stratospheric ozone destruction[1]. Halogenated species also contribute to global warming[2]. The significance of the anaesthetics in stratospheric ozone loss or in 'greenhouse' heating depends on their atmospheric lifetimes. Because reaction with hydroxyl (OH) radicals is likely to be the main homogeneous sink for these species in the troposphere, we have measured absolute rates of reaction with OH. Comparison with a one-dimensional model[3] indicates that the lifetimes of halothane, enflurane and isoflurane with respect to this reaction are 2, 6 and 5 years, respectively. Thus the small production of the anaesthetics is not offset by anomalously long atmospheric lifetimes to give a large atmospheric burden of the compounds. The anaesthetics will contribute at most a fraction of $\sim 5 \times 10^{-4}$ to the total atmospheric content of chlorine-containing species.

Halothane, enflurane and isoflurane are popular potent inhalation anaesthetics[4]. Almost all of the administered doses will end up in the atmosphere[5], but only those species with a tropospheric lifetime of more than about two years will reach the stratosphere in significant quantities.

The efficiency with which a unit mass of each anaesthetic will destroy stratospheric ozone relative to the most important ozone-depleting molecules, chlorofluorocarbons (CFCs) 11 and 12 (CFC-11 and CFC-12), will depend on the molecular weight of the anaesthetic, the number and type of halogen atoms per molecule and the compound's atmospheric lifetime[3]. The relative ozone-depletion potential (ODP) is given by

$$\mathrm{ODP} = \frac{\tau_{\text{An-H}}}{\tau_{\text{CFC-11}}} \times \frac{M_{\text{CFC-11}}}{M_{\text{An-H}}} \times \frac{n_{\text{Cl}} + \alpha n_{\text{Br}}}{3} \qquad (1)$$

where An-H represents the parent anaesthetic molecule, and $M_{\text{CFC-11}}$ and $M_{\text{An-H}}$ are the relative molecular masses of CFC-11 and the parent anaesthetic species, respectively. The total number of Cl and Br atoms in the molecule are represented by n_{Cl} and n_{Br}, and α is the efficiency of Br in destroying stratospheric ozone relative to that of Cl. According to current estimates[3], Br may be between 35 and 80 times more potent as a catalyst than Cl, so that the factor α must be taken into account in deriving ODPs.

The most important daytime degradation of the anaesthetic molecules will be[6] reaction with the OH radical

$$\text{An-H} + \text{OH} \rightarrow \text{An} + \text{H}_2\text{O}$$

Photolysis is another potential loss process, but the ultraviolet spectra of enflurane[7,8] and isoflurane show absorption onsets at $\lambda < 290$ nm, so that photolysis of these compounds does not occur in the troposphere—only in the stratosphere is there significant photolysis. For the bromine-containing species halothane, the onset of absorption seems[7] to be similar, but there may be a long-wavelength tail, as found for CF_2ClBr. The atmospheric lifetime of the latter compound against photolysis in the troposphere and lower stratosphere[3] is ~12.5 yr, and a similar photolytic lifetime might be expected for halothane. We have found that the reaction with OH is about six times faster, so that the rate of the above reaction will effectively determine the tropospheric lifetime τ (defined as $\{k_2[OH]\}^{-1}$) for all the compounds studied.

Our measurements of the second-order rate constants for the reactions between the OH radical and the anaesthetic reagents halothane, enflurane and isoflurane are given in Table 1. Data are also given for a further anaesthetic agent, sevoflurane ($CF_3CH(CF_3)OCH_2F$). As the molecule does not contain Cl or Br atoms, it does not pose a threat to stratospheric ozone, but it was included in our study as a potential 'greenhouse' gas. We used an absolute discharge-flow technique[9,10] to provide time resolution and resonance fluorescence to measure OH concentrations. The total pressures in the flow tube were ~2 torr; oxygen was not present. It is important to know if the rates of reaction with OH are significantly temperature dependent. By analogy with measured activation energies (E_a) for hydrogen-atom abstraction by OH from other halogenated organic compounds[11], we expected a value of E_a of ~10 kJ mol^{-1}. We obtained activation energies of ~8.6 and ~7.6 kJ mol^{-1} for the reactions with enflurane and sevoflurane by performing measurements at two temperatures (300 K and 422 K). This result is in accordance with expectation and, because the value is relatively low, it is not necessary to measure it more precisely or to determine it at temperatures below ambient. A temperature change from 300 K to 220 K induces a change in the rate by at most a factor of three.

We have estimated the tropospheric lifetime of each anaesthetic in two ways. First, we assume[12] a uniform OH-radical concentration of 7.7×10^5 molecule cm^{-3} and a tropospheric temperature of 300 K. The calculated values of τ and the relative ozone-depletion efficiencies (calculated from equation 1) are listed in Table 1. Second, we have scaled the lifetimes determined[3] in one-dimensional model calculations for methyl chloroform (CH_3CCl_3) and CFC-22 (CHF_2Cl) using the published[11] rate constants for reaction with OH for the latter compounds and our new measurements for the anaesthetics. The lifetime, longer by a factor of ~2.5, that we obtained using the second method probably reflects the more realistic treatment of the altitude dependence of both [OH] and temperature in the one-dimensional model. In assessing the catalytic activity for the halogen atoms released by halothane, $CF_3CHClBr$, we have used the ODP obtained from the Lawrence Livermore National Laboratory (LLNL) model[3] for the analogous compound CF_2ClBr as the basis for comparison in both methods.

Long-lived halogenated organic compounds can also contribute to global warming because of their intense absorptions, especially in the 'atmospheric window' between 800 and 1,200 cm^{-1} in the infrared[2]. The greenhouse warming potential (GHWP) of each anaesthetic can be calculated to a first approximation by comparing the integrated absorption cross-section, S, atmospheric lifetime, and molecular weight with CFC-12, defining the GHWP of CFC-12 to be unity[13] so that

$$\mathrm{GHWP} = \frac{\tau_{\text{An-H}}}{\tau_{\text{CFC-12}}} \times \frac{M_{\text{CFC-12}}}{M_{\text{An-H}}} \times \frac{S_{\text{An-H}}}{S_{\text{CFC-12}}} \qquad (2)$$

The infrared absorption spectra of halothane and enflurane have been reported[14] but we have not found any published values of the integrated absorption cross-sections of the anaesthetics. To estimate the GHWP of halothane, enflurane, isoflurane and sevoflurane we measured their infrared spectra with a commercial infrared spectrophotometer (Perkin-Elmer Type 881, 2.40 cm^{-1} resolution) and estimated their integrated absorption cross-sections in the range 800 to 1,200 cm^{-1} from the area under the peaks in the spectra. Experiments with isoflurane showed that the absorbance was a linear function of pressure between 2 and 7 torr of reactant. We observed no change in the absorption spectrum on adding up to 738 torr of N_2, or on cooling the absorption cell from 303 K to 271 K, so that at the resolution employed, the spectra are applicable to tropospheric conditions. Representative spectra for the region 600 to 1,600 cm^{-1} are shown in Fig. 1; integrated absorption cross-sections in the range 800 to 1,200 cm^{-1} and the corresponding GHWPs are listed in

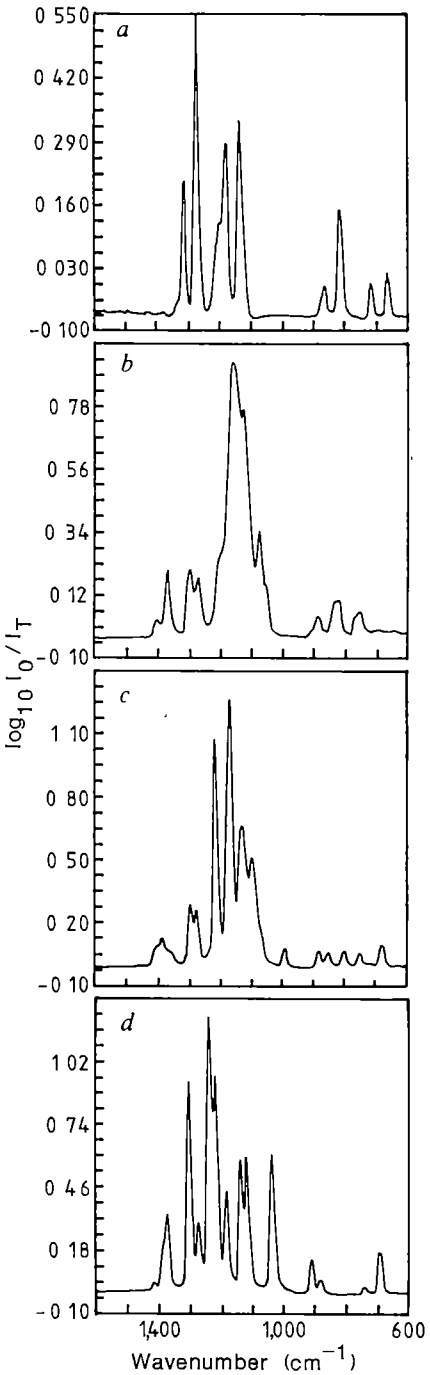

FIG 1 Infrared spectra of *a*, halothane (2 7 torr), *b*, enflurane (3 1 torr), *c*, isoflurane (3.1 torr), and *d*, sevoflurane (3 1 torr).

Table 1. The most intense features are ether-group stretches in the range 1,000–1,200 cm^{-1}, bands not present in CFCs.

The major uncertainties in our estimate of the tropospheric lifetime of the An-H species are the extent to which the anaesthetics are removed from the atmosphere by further processes such as 'rain-out' and the modelling of global tropospheric OH concentration and temperature. Nevertheless, the relatively short lifetimes of the anaesthetics mean that both the potentials for ozone depletion and the GHWPs are much smaller than for CFC-11 or CFC-12. In addition to the small potentials, the global market for the anaesthetics (1,000, 220 and 800 tonnes for halothane, enflurane and isoflurane[5]) is much less than for CFC-11 and CFC-12 (350,000 and 400,000 tonnes[15]). Thus the overall contribution to ozone depletion or greenhouse warming by the anaesthetic agents must be less than 5 parts in 10^4 of that produced by the CFCs. □

Photochemical source of biological substrates in sea water: implications for carbon cycling

David J. Kieber*†, Julie McDaniel*† & Kenneth Mopper*‡

* Rosenstiel School of Marine and Atmospheric Science, University of Miami, 4600 Rickenbacker Causeway, Miami, Florida 33149, USA

DISSOLVED organic carbon (DOC) in sea water represents one of the largest reservoirs of carbon on the earth[1]. The main fraction of this DOC is generally believed to be composed of old[2], biologically refractory material[3] such as humic substances, for which the removal mechanisms remain largely unknown. One potentially important removal process in the ocean that has not been investigated is the photochemical breakdown of this DOC in the photic zone to form biologically labile organic products. Here we show that biological uptake of pyruvate is highly correlated to its rate of photochemical production in sea water ($r = 0.964$), and that the photochemical precursor(s) of pyruvate is from the fraction of DOC having a nominal molecular weight of 500. This is the first evidence that photochemical breakdown of high-molecular-weight marine DOC, which is presumably biologically refractory, results in the production of a compound that is used by plankton as a substrate. Our results have important implications for the oceanic carbon cycle, particularly with respect to planktonic-food-web dynamics and the global carbon budget.

We collected surface seawater samples from a variety of coastal and oligotrophic stations (Fig. 1) during the SOLARS (Study of Light Activated Reactions in the Sea) cruises. Details of sampling procedures will be presented elsewhere (D.J.K. *et al.*, manuscript in preparation). Briefly, we determined the biological uptake of pyruvic acid by measuring its ambient substrate concentration S_n by high-performance liquid chromatography[4] and determining the turnover time t_n of pyruvate at S_n using the respiration-corrected kinetic approach[5]. Typical S_n values ranged from 0.2 to 2.0 nM for oligotrophic stations and 0.9 to 6.2 nM for coastal stations. We added [2-^{14}C]-labelled pyruvate to unfiltered seawater samples to obtain concentrations in the range 10–120 nM; we added glutaraldehyde to pyruvate controls trols to account for abiological processes (such as adsorption

onto particles). We incubated the samples in acid-washed polycarbonate bottles placed in a water bath and exposed to sunlight. There is evidence that light inhibits uptake of organic substrates[6]; nevertheless, the incubations were done under light conditions because this most closely reflected ambient conditions in surface sea water. In cases where we made light-dark comparisons to estimate the magnitude of photoinhibition of uptake, the light rates of pyruvate uptake were within 20% of the corresponding dark rates (D.J.K. *et al.*, unpublished results). Samples were incubated from 0.2 to 1.7 h at coastal stations and from 3 to 13 h for offshore sites in the Gulf Stream and the Sargasso Sea. We chose incubation times such that, in most instances, the substrate uptake was <10% at the lowest addition; we measured the amount of label assimilated as well as the amount respired to carbon dioxide. The turnover time is the vertical-axis intercept of the plot of the incubation time divided by the fraction of isotope taken up as a function of concentration of added pyruvate. Time-course experiments performed at each station showed that the uptake of pyruvate in all cases was linear during incubations[7] (D.J.K. *et al.*, manuscript in preparation). After determining S_n and t_n, we can calculate the uptake rate of pyruvate V_n at the ambient substrate concentration from the equation:

$$V_n = S_n / t_n$$

Concurrent with uptake studies, we exposed 0.22-μm-filtered seawater samples to sunlight to determine rates of photochemical production of pyruvate. Irradiations, ranging from 1 to 3 h, were carried out at midday between 10:00 and 14:00 local time. Sample filtration has no significant effect on photochemical production rates of pyruvate when performed carefully (such as gravity filtration through a Whatman GF/C filter followed by vacuum filtration through a 0.22-μm nylon filter at a pressure differential ≤100 mm Hg)[4].

Using data from several field locations, we plotted the uptake rate of pyruvate at S_n against its rate of photochemical production (Fig. 2). Linear regression analysis of the data was performed using a method[8] in which it is assumed that uncertainty is associated with the determination of both variables. The results of this analysis show that uptake rates of pyruvate are

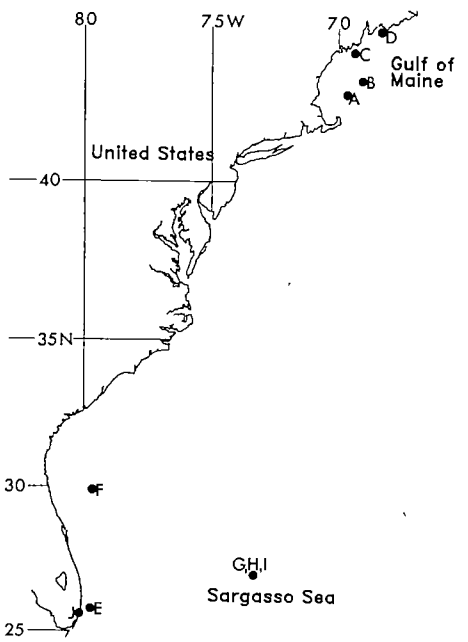

FIG 1 Map of sampling locations Gulf of Maine *a*, Wilkinson Basin, 42°35 2′ N, 69°34.9′ W; *b*, Ammen Rock, 42°53 8′ N, 68°56 6′ W; *c*, Monhegan Island, 43°44 4′ N, 69°19 2′ W; *d*, Acadia National Park, 44°17 7′ N, 68°10 7′ W Gulf Stream. *e*, 25°58 5′ N, 79°42 5′ W; *f*, 30°10 4′ N, 79°33 8′ W Sargasso Sea *g*, 27°21 4′ N, 73°12 6′ W; *h*, 27°20 9′ N, 73°14 9′ W, *i*, 27°21 4′ N, 73°16.4′ W Biscayne Bay, Florida *j*, 25°41.0′ N, 80°08 1′ W

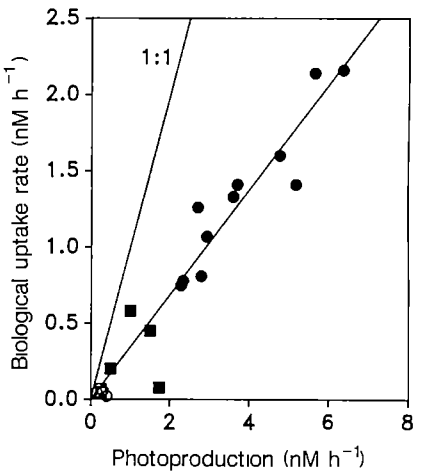

FIG 2 Biological uptake rate of pyruvate plotted against its midday rate of photochemical production The line drawn through the data was determined from linear regression analysis The 1.1 line (slope=1) depicts the case where photochemical production and biological uptake rates are equal Different symbols represent different sampling locations (○) Sargasso Sea, (□) Gulf Stream, (■) Gulf of Maine and (●) Biscayne Bay, Florida

strongly correlated to its rates of photochemical production, $r = 0.964$, $n = 20$, slope $\pm 1\sigma = 0.35 \pm 0.03$. Based on the inverse of the regression slope, the midday rates of photochemical production are larger than corresponding rates of biological uptake by a factor of approximately three. We expect this relationship to vary both vertically in the water column and as a function of the solar light flux. Imbalances in rates of uptake and photo-production should give rise to diurnal variations in the concentration of pyruvate in surface waters, when other physical factors (such as vertical mixing) are relatively unimportant. We have observed diurnal variations at several coastal locations (D.J.K. *et al.*, manuscript in preparation) and these variations can be simulated readily in the laboratory[4] using filtered and unfiltered sea water. In one field study[7], maximum daytime concentrations were ~4.0 nM whereas night-time concentrations were as low as 0.5 nM. We have observed similar diurnal variations for other photochemically generated biological substrates in sea water, including glyoxylate and formaldehyde; we will discuss the details of these studies elsewhere. These results support the direct relation between the photochemical production and biological uptake of pyruvate shown in Fig. 2. Another important feature depicted in Fig. 2 is that both biological uptake and photochemical production rates are generally higher at coastal locations (Biscayne Bay in Florida and the Gulf of Maine) than at oligotrophic sites in the Gulf Stream and the Sargasso Sea.

Our results clearly show that there is strong correlation between rates of uptake and photochemical production of pyruvate in surface waters. However, these processes may be only incidentally related and may be a consequence of variations in other parameters such as the concentration of dissolved organic matter (DOM). On the other hand, it is quite reasonable to expect that bacteria have adapted to varying concentrations of photochemically produced substrates in the photic zone, such as we observe for pyruvate. Therefore, we expect a direct coupling of uptake rates to production rates, as has been shown for the biological turnover of amino acids using an isotope dilution technique.[9]

We performed ultrafiltration experiments to obtain information regarding the photochemical source(s) of pyruvate in sea water. Filtered sea water collected from the Sargasso Sea or Biscayne Bay was fractioned through a YC05 Amicon ultrafiltration membrane with a nominal molecular-weight cutoff of 500 (ref. 7). Filtered (0.22 μm) Sargasso sea water and Biscayne Bay water showed photochemical production of pyruvate at rates of 1.1 and 5.3 nM W^{-1} hr^{-1} m^{-2} respectively (Fig. 3). By contrast,

we observed no photochemical production of pyruvate for either sample in the fraction of DOM having a nominal molecular weight <500. In fact, we observed a slight loss, as expected, because pyruvate (and other α-keto acids) undergo photochemical decarboxylation in sea water[7] (D.J.K. *et al.*, manuscript in preparation). Although high-molecular-weight DOM seems to be the principal photochemical source of pyruvate, it is not possible, on the basis of ultrafiltration alone, to discern whether the precursors consist of biologically refractory or biologically labile material. There is some evidence, however, that suggests that the precursors are in fact biologically refractory. Sargasso sea water used here was collected from 3,000 m; previous investigators have shown that DOM from this depth is biologically refractory in nature[10-13]. The refractory nature of this DOM is also indicated by its mean residence time (based on ^{14}C measurements) of >6,000 yr (ref. 2).

A critical assumption of our hypothesis is that there exists a large pool of DOM in the oceans that is biologically refractory. There are many lines of evidence supporting this idea (for review see ref. 1); however, these studies are not without uncertainties. Further studies are needed to define more clearly whether photochemical production of biologically labile products originates from a biologically refractory pool of DOM. Does this pathway present a new input of biologically labile DOM in the photic zone, or does it simply involve transformations of DOM that is already biologically labile?

In the planktonic food web[14], phytoplankton are generally believed to be the major source of DOM[15,16] for bacteria. If the magnitude of photochemical production of biologically labile compounds is large in the sea, particularly with respect to oligotrophic environments, then this photochemical pathway may represent an important non-phytoplankton source of DOM available to bacteria. We have calculated a rough estimate of the photochemical flux of biologically labile DOM, specifically DOC, to heterotrophic bacteria relative to the flux from primary productivity in the Sargasso Sea. Given a total daytime (8 h of sunlight) photochemical production of pyruvate of ~4 nM per day in the upper 10 m, the corresponding DOC input is 1.6 mg C m^{-2} per day. This input is ~1% of the primary productivity[17] (typical value 200 mg C m^{-2} per day) in the Sargasso Sea. Assuming that pyruvate is primarily taken up by bacteria and that 10–50% of primary productivity passes through heterotrophic bacteria on a daily basis[18,19], then the photochemical flux of pyruvate is 2–4% of the total carbon flux to bacteria. Even though this percentage is small, it is based on the photochemical production only of pyruvate. It is reasonable to expect that a wide variety of other easily utilized biological substrates of low molecular weight are formed by the photochemical breakdown of biologically refractory DOM (acetate, acetaldehyde, formate, formaldehyde, glyoxylate, carbon monoxide, methanol, for example); several of these have already been identified[4,20,21]. When the production rates of these compounds are summed, photo-oxidation of biologically refractory DOM may well be a significant source of DOM to bacteria, especially if bacterial growth in oligotrophic environments is carbon-limited in some instances[22]. In addition to the production of common biological substrates, photochemical alteration of the DOM residue may also render it more susceptible to microbiological attack, as has been shown for fresh-water DOM[23]. Depending on the products formed and the relative uptake of these products by different bacteria, these carbon fluxes may be a determinant in the structure of the microheterotrophic community in the upper ocean.

We have shown that photochemical fragmentation of biologically refractory DOM (such as humic substances) results in the formation of biologically labile compounds (such as pyruvate) and that biological uptake of these photochemical products is strongly coupled to their rate of photochemical production in surface sea water. Rough calculations indicate that this overall process is important in the removal of oceanic DOC, and probably also accounts for the rapid degradation of riverine organic carbon inputs into the sea. These calculations, as well as further evidence supporting this latter hypothesis, will be presented elsewhere (K.M. *et al.*, manuscript in preparation). □

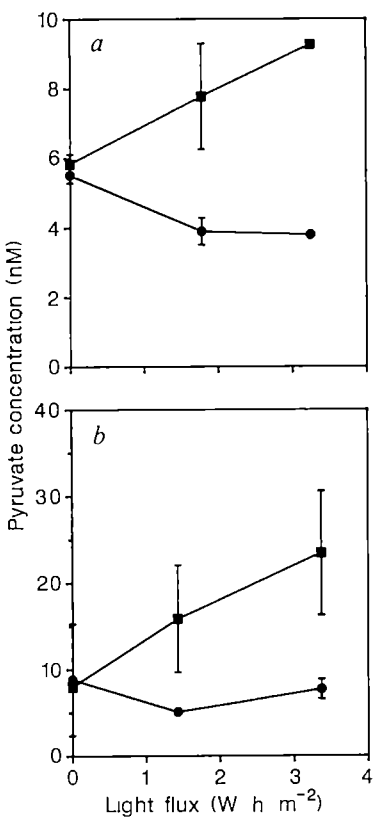

FIG 3 Plot of the concentration of pyruvate as a function of the near-ultraviolet light flux (<385 nm) in sea water that is 0.22-μm filtered (■) or fractioned by ultrafiltration using a membrane with molecular-weight cutoff of 500 (●). It is assumed that the difference in production rates between these two fractions is equal to the rate of photochemical production in the fraction greater than a nominal molecular weight of 500. *a*, Sargasso sea water collected at 3,000 m, and *b*, Biscayne Bay sea water. The vertical bar represents the range of the data ($n=2$); no vertical bar was drawn when the range of the data was smaller than the diameter of the symbol. Note the difference in the scale of the vertical axis between *a* and *b*.

THE increase in sulphur content of organic matter with depth in Recent sediments has been attributed to incorporation of either H_2S (ref. 1) or polysulphides[2,3] or to a combination of both[4,5]. Indeed, the widespread occurrence of organic sulphur compounds[6–12] with carbon skeletons that bear an unambiguous link with natural precursors indicates that organic matter may act as a sink for inorganic sulphur species with an efficacy second only to reactive iron minerals[13]. Laboratory and field observations[14–18] indicate that all compounds identified so far are consistent with incorporation of H_2S; molecular evidence for incorporation of polysulphides has previously been lacking. Here we report the identification of homologous series of cyclic disulphides with a linear carbon skeleton and of a cyclic di- and trisulphide with a C_{20} isoprenoid carbon skeleton in sediments of Quaternary to Pliocene age. Although incorporation of H_2S can still explain the presence of cyclic disulphides, the cyclic trisulphide implies incorporation of inorganic polysulphides in sedimentary organic matter at the earliest stages of diagenesis.

Several organic-carbon-rich sediment samples of Quaternary to Pliocene age from the Peruvian upwelling area[19] and a bituminous shale of Messinian age (upper Miocene) from the Vena del Gesso basin (located in the northern Apennines[20]) were extracted. Gas chromatographic analyses with dual flame ionization detection and flame photometric detection of the aromatic hydrocarbon fraction isolated from the extracts[11,19] revealed the presence of compounds containing more than one sulphur atom.

In the Vena del Gesso sample, two homologous series of compounds with two sulphur atoms are most abundant, whereas in several of the Peruvian samples a compound with three sulphur atoms dominates the aromatic hydrocarbon fractions together with the polycyclic aromatic hydrocarbon perylene. The major homologous series occur as doublet peaks (Fig. 1*a*) with identical mass spectra, all characterized by an intense fragment ion at $M^+ - 33$ (–SH, based on exact mass measurements), a minor ion at $m/z = 133$ ($C_5H_9S_2$) and several secondary-fragment ions (for example, $m/z = 101$, 143 and 185) which are also observed in mass spectra of 5-alkyl-2-methylthiolanes[8,10,21]. Loss of SH from the molecular ion has been reported for dithianes[22,23]. The major products of Raney nickel desulphurization[10] of the sulphide fraction (isolated by argentatious thin-layer chromatography), followed by hydrogenation, were *n*-alkanes. These characteristics indicate that a series of stereoisomers of 3-*n*-alkyl-6-methyl-1,2-dithianes (C_{15}–C_{24}) occurs in this sample. Synthesis of the major members (*cis* and *trans* 3-methyl-6-tridecyl-1,2-dithiane, C_{18}; compound I), for which details are described elsewhere[24], and subsequent co-injections on capillary columns of different polarity confirmed this assignment.

Mass chromatography of the molecular ions of the cyclic disulphides ($274 + 14n$) revealed the presence of C_{20} compounds (compound II, Fig. 1*b*), eluting much earlier than the C_{20} dithianes with linear carbon skeletons. The only notable difference in their mass spectra is the shift of fragment ion $m/z = 143$ to $m/z = 157$, a characteristic ion of 3-methyl-2-(3,7,11-trimethyldodecyl)thiolane[10]. Raney nickel desulphurization also gave a substantial amount of phytane. Hence these compounds are believed to be *cis* and *trans* 4-methyl-3-(3,7,11-trimethyldodecyl)-1,2-dithianes (compound II). A third isoprenoid cyclic disulphide is tentatively identified as 4-(4,8,12-trimethyltridecyl)-1,2-dithiane (compound III) based on its gas-chromatographic retention time and mass spectrum. These

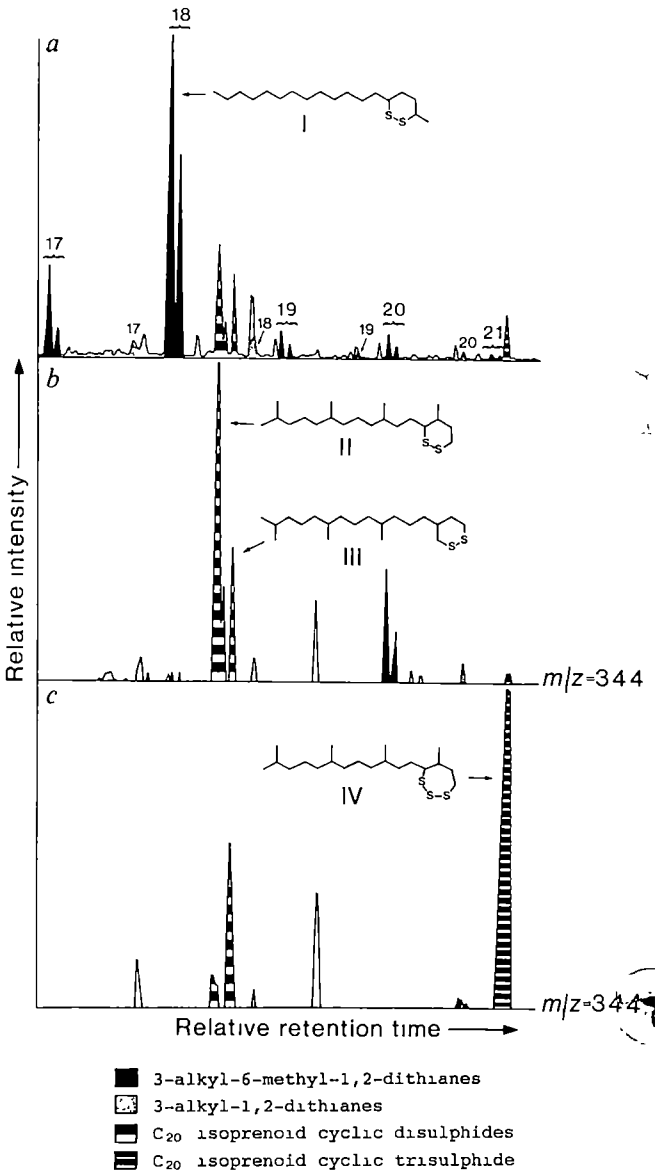

FIG. 1 *a*, Partial reconstructed ion chromatogram of the aromatic hydrocarbon fraction of bituminous shale from the Vena del Gesso basin *b*, Partial-mass chromatograms of $m/z = 344$ of the aromatic hydrocarbon fractions of a bituminous shale from the Vena del Gesso basin *c*, Mottled diatomaceous ooze from the Peruvian upwelling area (ODP 112-684C-4H-7, 30–37 cm; 36.15 m sub-bottom depth) The carbon numbers of the homologous series of *cis* and *trans* 3-*n*-alkyl-6-methyl-1,2-dithianes and 3-*n*-alkyl-1,2-dithianes are indicated in *a* Minor compounds, not indicated in *a*, are mainly homologous series of 2-*n*-alkylthiophenes and 2-*n*-alkyl-5-methylthiophenes Compounds I to IV are discussed in the text Instrumental conditions were a Carlo Erba Fractovap 4160 gas chromatograph equipped with a Hewlett-Packard fused-silica capillary column (length, 50 m, inner diameter, 0.31 mm) coated with Ultra 2 (film thickness, 0.52 μm) Temperature increased from 110 °C to 320 °C at a rate of 3 °C min^{-1} Helium was used as the carrier gas. The gas chromatograph was connected to a VG-7070E mass spectrometer operating at 70 eV Exact mass measurements were performed by peak matching using selected masses from perfluorkerosine as the reference and a resolution of 5,000 with a VG-70S mass spectrometer operating at an ionization voltage of 70 eV.

isoprenoid cyclic disulphides were also present in most of the Peruvian samples, although the linear 1,2-dithianes were virtually absent (Fig. 1*c*). However, the most important extractable organic sulphur compound (compound IV, which is sometimes the most abundant compound of the aromatic hydrocarbon fraction) gives a mass spectrum with a molecular ion at $m/z = 376$ ($C_{20}H_{40}S_3$; based on exact mass measurements), an ion at $m/z = 344$ ($M^+ - 32$), and a fragmentation pattern similar to that observed for the C_{20} isoprenoid 1,2-dithianes ($m/z = 101$, 157, 255 and 311). Loss of sulphur from a parent ion ($M^+ - 32$) has been reported for molecules with two or more adjacent sulphur atoms[21,25–27]. The product of Raney nickel desulphurization of the aromatic hydrocarbon fraction is almost solely phytane. This compound was therefore identified as 5-methyl-4-(3,7,11-trimethyldodecyl)-1,2,3-trithiepane (compound IV). This cyclic trisulphide also occurs as a minor compound in the bituminous shale of the Vena del Gesso basin (Fig. 1). We note that the sporadic occurrence of compound IV in the Peruvian sediments excludes its formation after sample preparation.

The structures of these novel organic sulphur compounds cannot be related to known naturally occurring di- and trisulphides[28]. By analogy with the hypothesis put forward to explain the origin of other organic sulphur compounds[6–11], the incorporation of abiotic sulphur into specific functionalized lipids can explain their occurrence. For example, phytadienes (derived from ubiquitous phytol) can act as suitable precursors for the newly identified C_{20} isoprenoid cyclic di- and trisulphides. In contrast to previously suggested incorporation models[11], addition of H_2S cannot be invoked to explain the occurrence of a C_{20} isoprenoid cyclic trisulphide. The cyclic disulphides may still originate from reactions of H_2S through intermediate dithiols which, after oxidation, may yield 1,2-dithianes. Chemically and/or microbially generated inorganic polysulphides[29,30] are suitable sulphur species for the formation of cyclic trisulphides, although also microbially produced polysulphides occur the most prominent ones occurring in natural aqueous solutions[29] are HS_4^-, HS_5^-, S_4^{2-} and S_5^{2-}.

It is known[28,31] that organic polysulphides are thermally unstable and therefore we suggest that if tetra- and pentasulphides are formed they will easily degrade to tri- and disulphides during prograde diagenesis. This also implies that the latter compounds may be seen as potential precursors for sulphides (thiolanes). We note that the younger and less deeply buried Peruvian sediment samples contain the trisulphide in high abundance in comparison to disulphides, a situation which is reversed in the older and once more deeply buried bituminous shale from the Vena del Gesso basin (Fig. 1).

Di- and trisulphides may prove to be useful tools for the reconstruction of palaeoenvironments because the occurrence of inorganic polysulphides is known to be sensitive to variations of the pH and redox potential Eh[29]. □

Phytoplankton production pulses and episodic settlement of a temperate marine fish

Ronald E. Thresher, Graham P. Harris, John S. Gunn & Lesley A. Clementson

CSIRO Marine Laboratory, GPO Box 1538, Hobart, Tasmania 7001, Australia

THE settlement of post-larval marine invertebrates[1,2] and fishes[3–5] fluctuates massively both within and between years; this variability significantly affects the structure of adult populations[5,6]. The causes of these fluctuations are not well known, but they are typically attributed to variation in some element of the planktonic environment that determines the distribution and rates of survival of the larvae[3,7–9]. Here we report that over a three-year period, pulses of settlement of a species of temperate reef fish were invariably preceded by brief, irregularly occurring peaks of phytoplankton production. The lag time was consistent with a 'critical period' hypothesis[10], in which settlement rates are determined by irregular variation in the availability of food for newborn larvae. Although they are difficult to detect, transient but intense pulses of production may be common in the oceanic water column[11] and could underlie the extreme temporal variability of settlement characteristic of many marine organisms.

The viviparous rocky reef fish *Heteroclinus* sp. ("Scott's Weedfish" in ref. 12), occurs in large numbers in tide pools and shallow reef areas along the coast of southern Australia. During a parturition season that lasts from October to late December, females produce clutches of up to 2,700 larvae asynchronously about every 17 days (J.S.G. and R.E.T., unpublished manuscript). At birth, the larvae vary from 7.1–9.4 mm Standard Length, are active swimmers and are well developed, with functional jaws and eyes, no evident yolk sac and an open gut. The larvae of this and other clinid species are found predominantly inshore, in coastal bays and inlets. The duration of the planktonic larval stage varies seasonally from 3 to 6 weeks, after which the fish settle as lightly pigmented juveniles, 14–16 mm Standard Length, in tide pools and shallow rocky habitats.

We measured seasonal variability in settlement by *Heteroclinus* sp. for three years (1985/86 to 1987/88) by sampling every two weeks at sites around Storm Bay, a large semi-autonomous[13] embayment in southeastern Tasmania (43° 20'S, 147° 30' E). The date on which each juvenile settled was determined by examination of otolith microstructure[14]. Over the same period we measured phytoplankton abundance weekly at a station near

the centre of Storm Bay. Phytoplankton abundance was quantified by chlorophyll levels, using the hot-methanol extraction method[13].

The number of newly settled *Heteroclinus* sp. collected per sample varied widely and irregularly each spawning season. The patterns of temporal variation in settlement differed markedly between years. One large prolonged peak dominated settlement in 1985/86; two small peaks, separated by several weeks of almost no settlement, were evident in 1986/87; in 1987/88, there was little settlement early in the year, but thereafter settlement was continuous, with two peak periods separated by about 5 weeks (Fig. 1, top).

The temporal pattern of settlement each year matched that of chlorophyll levels in Storm Bay several weeks earlier (Fig. 1, bottom). Over the three-year period, all the main peaks in settlement could be matched to a corresponding peak in chlorophyll levels 7–9 weeks earlier (modally 7 weeks); conversely, there were no peaks in chlorophyll levels that were not followed by a pulse of settlement. A Spearman rank correlation between numbers of settling fishes and preceding chlorophyll levels is significant ($P < 0.05$) in each of the three years, at identical lag times (the correlations are significant at lags of 6, 7 and 8 weeks in 1985/86, 7 and 8 weeks in 1986/87, and 7 and 8 weeks in 1987/88). The correlation between chlorophyll levels and settlement, pooled by calendar week, accounts for 56%, 37% and 23% of the variance in settlement for the 1985/86, 1986/87 and 1987/88 years, respectively.

By contrast, chlorophyll levels do not correlate significantly with subsequent settlement when years are pooled (maximum Spearman rank correlation coefficient $r_s = 0.23$, $n = 40$, lag of 8 weeks), reflecting a poor relationship between year-class strength (total number of newly settled fishes per annum) and mean annual chlorophyll levels. Nor is there any apparemt relationship among years between year-class strength and the minimum, maximum, variability (coefficient of variation) or sum of chlorophyll levels each year. Across years, settlement peaks coincide (after lagging) with chlorophyl levels greater than $\sim 2 \mu g^{-1}$, but the magnitude of settlement often shows no relation to the magnitude of the corresponding peak in chlorophyll.

The lag between chlorophyll level and settlement is consistent with the hypothesis that variations in food availability for newborn larvae determine settlement rates. Gut contents of *Heteroclinus* larvae less than 5-days-old consist almost entirely of small copepods and similar sized microzooplankton. The abundance of these microzooplankton in the weekly samples correlates strongly with that of phytoplankton, peaking 1–4 weeks (highest cross-correlation at a lag of 2 weeks) after each phytoplankton peak (G.P.H., L.A.C. and F. B. Griffiths, manuscript in preparation). These larvae spend, on average, 4 weeks in the plankton ($\bar{x} = 28.8$ days, $n = 511$, years pooled), varying seasonally from a mean of ~6 weeks early in the spawning season to 3.5 weeks in mid-summer. The sum of the chlorophyll–microzooplankton lag and the duration of the fish's larval stage, therefore, ranges from ~4.5–9 weeks, and averages 6–7 weeks. This compares with a correlation between chlorophyll level and settlement at lags that range from 6–8 weeks and average 7 weeks.

It is not possible to falsify the hypothesis that the temporal patterns of production and settlement are independent responses to a third, forcing function. Nonetheless, we consider this possibility unlikely. The timing of chlorophyll peaks in Storm Bay is determined by episodic bouts of strong winds, which turn over the water column and result in nutrient enrichment and, about three weeks later, a phytoplankton bloom (G.P.H., L.A.C. and F. B. Griffiths, manuscript in preparation). Hence the physical event responsible for chlorophyll peaks occurs, on average, 10 weeks before the settlement peaks and 5 weeks before the birth of the larvae that constitute those peaks. If wind events directly determine settlement variation, then they would have to operate by affecting pregnant females, producing short-term variability in brood size or larval competence. Brood sizes, however, are set before the onset of the parturition season, and neonate size, at least, varies only slightly seasonally and does not correlate with settlement variability (J.S.G. and R.E.T., unpublished manuscript). Alternative hypotheses based on, for example, the effects of wind on patterns of larval advection are possible, but difficult to reconcile with the lag times observed. Moreover, water-mass characteristics indicate that exchange in and out of Storm Bay is relatively slow[13] and that the large scale episodic flushing that would be required to cause marked variability in settlement is unlikely.

Observations of the larvae in aquaria also support the hypothesis that short-term variations in food availability directly mediate the link between water-column production and settlement rate. As yet, we have been unable to get newborn *Heteroclinus* larvae to feed; all but a few of the several thousand larvae that we have produced in the laboratory died, apparently of starvation, within 12 h after birth. The short period to starvation is consistent with the lack of yolk sacs of these larvae at birth[15]. Older larvae, however, collected in the field and held under the same conditions, fed readily and metamorphosed as expected.

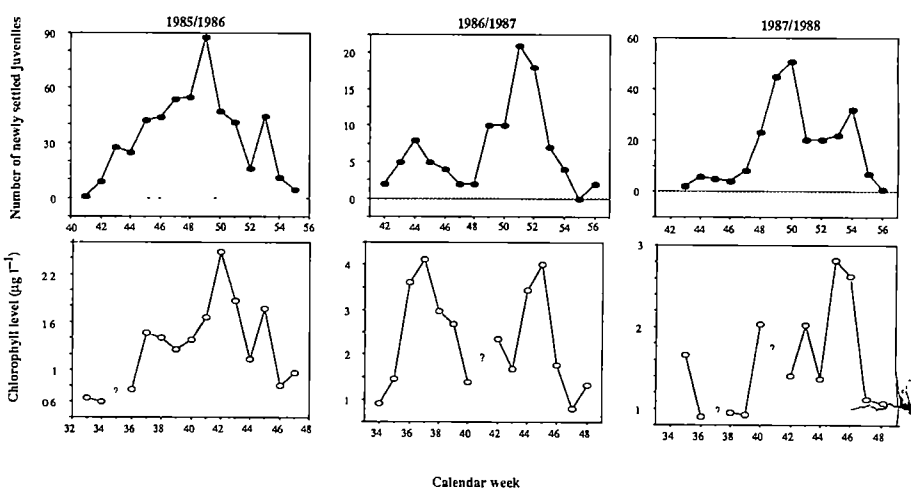

FIG 1 Total numbers of newly settled *Heteroclinus* sp recruiting to three sampling sites in Storm Bay, pooled by calendar week, in the 1985/86, 1986/87 and 1987/88 reproductive seasons Note the different scales on the ordinates Bottom, temporal variation in chlorophyll levels 8 weeks before the beginning of the reproductive season each year of *Heteroclinus* sp measured at a weekly sampling station near the centre of Storm Bay Question marks represent missing data. Note that the first main peak in settlement in 1987/88 occurred 8 weeks after a missing datum for chlorophyll levels Although we cannot be certain of a production peak that week, chlorophyll levels rose abruptly the week before the missing sample (as did settlement 8 weeks later), and the missing sample was preceded by a short duration nutrient pulse (see ref 13), both of which are consistent with a peak in chlorophyll during the missing period

If *Heteroclinus* larvae must eat very soon after birth, as our experience and the absence of yolk reserves indicates, then it is plausible that short-term variations in microzooplankton abundance could markedly affect the numbers of larvae that survive the first 24 h after birth, along the lines of the critical period hypothesis previously suggested to account for inter-annual variations in recruitment success[10].

Short-term transients of nutrient enrichment and subsequent phytoplankton production, on time scales of hours to days, can result from a range of oceanographic features, including meso-scale eddy formation[11], storm surges[16], current meanders[17] and tidally induced internal density waves (solitons)[18]. Although difficult to detect because of the temporal and spatial limitations imposed by ship-based sampling[11,19], these transients have recently been suggested to have importznt consequences for biogeochemical cycling and productivity in the ocean[19,20]. Our data indicate that these transients also underlie the extreme temporal patchiness of settlement by marine organisms and may have profound effects on the population ecology of such organisms. □

Cortical magnification factor and the ganglion cell density of the primate retina

Heinz Wässle, Ulrike Grünert, Jürgen Röhrenbeck & Brian B. Boycott*

Max-Planck-Institut für Hirnforschung, Deutschordenstrasse 46, D-6000 Frankfurt 71, FRG

IT has long been contentious whether the large representation of the fovea in the primate visual cortex (V1)[1–8] indicates a selective magnification of this part of the retina[7,9–11], or whether it merely reflects the density of retinal ganglion cells[12–14]. The measurement of the retinal ganglion-cell density is complicated by lateral displacements of cells around the fovea and the presence of displaced amacrine cells in the ganglion cell layer. We have now identified displaced amacrine cells by GABA immunohistochemistry and by retrograde degeneration of ganglion cells. By reconstructing the fovea from serial sections, we were able to compare the densities of cones, cone pedicles and ganglion cells; in this way we found that there are more than three ganglion cells per foveal cone. Between the central and the peripheral retina, the ganglion cell density changes by a factor of 1,000–2,000, which is within the range of estimates of the cortical magnification factor[1–8]. There is therefore no need to postulate a selective magnification of the fovea in the geniculate and/or the visual cortex.

There are three main problems in quantifying the ganglion cell density gradient of a primate retina. First, the population of displaced amacrine cells has to be estimated. In all mammalian retinae it is difficult to distinguish displaced amacrine cells from ganglion cells[15,16]. Second, in the fovea, the spatial offset between cone inner segments and ganglion cells due to the cone fibres (Henle fibres, Fig. 2*e*) makes it difficult to estimate the highest sampling density of ganglion cells[17–19]. Finally, the density of cells in the foveal region changes so rapidly with eccentricity that pooling data from experiments involving different animals, as well as different methods and shrinkage factors, produces inaccuracies. In the study reported here we have attempted to overcome these difficulties.

To differentiate ganglion cells from displaced amacrine cells, ganglion cells were retrogradely degenerated by interrupting their axons, and the surviving neurons were counted (Fig. 1*a*, *b*). The density of these neurons decreased from 3,500 cells mm^{-2} close to the fovea to ~500 cells mm^{-2} in the peripheral retina (Fig. 3). Selected fields of this retina were processed for GABA (γ-aminobutyric acid)-like immunoreactivity. Between 80 and 90% of the surviving neurons were stained. The number of neurons in the ganglion cell layer (GCL), which expressed GABA-like immunoreactivity, was also counted in a normal monkey retina (Fig. 1*d*). Close to the fovea a peak of 3,000 cells mm^{-2} was found, and the number decreased to ~500 cells mm^{-2} in the peripheral retina. These data show that most (80–100%) of the neurons that survive retrograde degeneration are GABA-ergic displaced amacrine cells.

Foveal topography was studied from the distribution of cone inner segments, cone pedicles and ganglion cells within the central 3 mm of one monkey retina. Cone density (Fig. 2*a*) decreased from a peak of 250,000 mm^{-2} in the fovea to ~11,500 mm^{-2} at 3 mm eccentricity. There are very few cone pedicles in the centre of the fovea (Fig. 2*b*). By 200 μm eccentricity, their density increases steeply, flattens out at 500 μm eccentricity and peaks in a plateau at 800 μm eccentricity, corresponding to a density of 32,000 mm^{-2}. Close to the fovea the pedicles tend to be elongated circumferentially and are densely packed in a regular way (Fig. 1*c*). The ganglion cell density curve (Fig. 2*c*) is comparable to the density curve for the cone pedicles; up to 2.5 mm eccentricity, however, there are substantially more ganglion cells than cone pedicles (see Fig. 2*d*). There is a plateau at 800 μm eccentricity corresponding to a maximum ganglion cell density of 60,000 mm^{-2}. These data are not corrected for shrinkage; the linear shrinkage factor was 0.9 and the areal was 0.8.

Figure 2*e* represents the geometry of the fovea. The foveal cone pedicles are displaced from their inner segments by Henle fibres as long as 350 μm[17–19]. Between cone pedicles and ganglion cells there is a further displacement of ~50 μm owing to obliquely running bipolar processes and ganglion cell dendrites[19]. These displacements must be allowed for to determine which ganglion cells are connected to which cones. As illustrated in Fig.2*e*, it is possible to get the ratio of ganglion cells to cones of the fovea from a cumulative count. The most central 10,000 cones must be connected to the most central 10,000 cone pedicles, because the Henle fibres have an orderly mapping[19–21]. The radius of the circle that includes these 10,000 cone pedicles

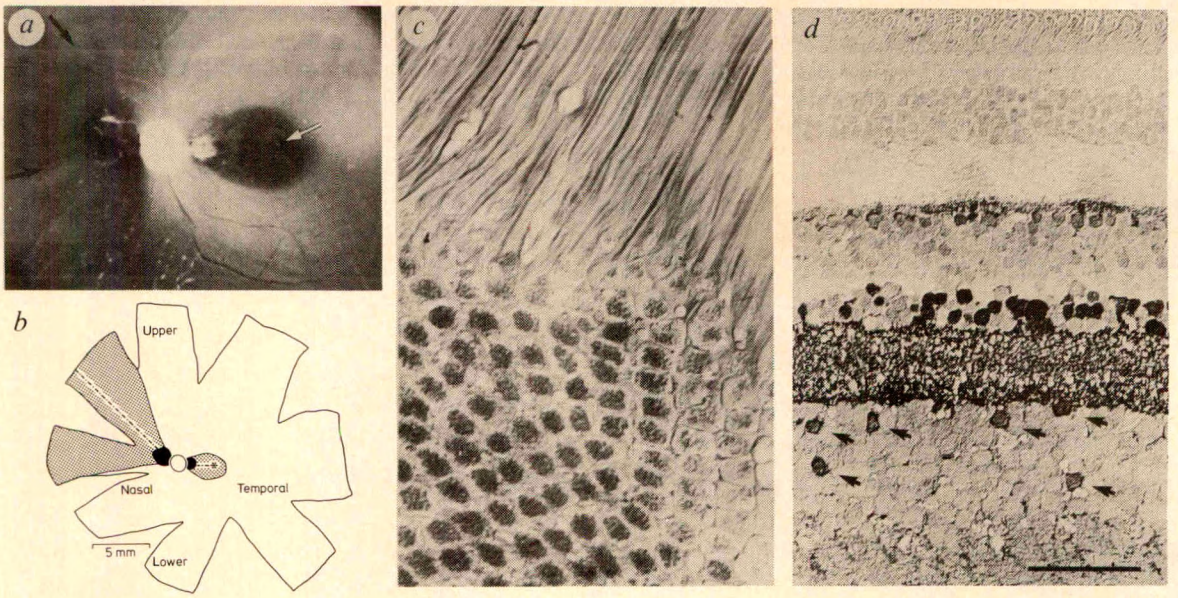

FIG. 1 *a*, Left eye cup of a macaque monkey with retrograde degeneration of ganglion cells produced by two small lesions. They were made in the intact eye using a xenon photocoagulator; the animal was anaesthetized with Ketanest and Rompun. The right eye was left intact, and during the 4-month survival period the animal showed no obvious visual deficiencies. It was killed by an overdose of nembutal and the eyes were enucleated and opened. The white spot in the centre is the optic-nerve head flanked by the two lesions (marked black in *b*). In the temporal retina, an oval black area including the fovea (white arrow) is apparent: the shiny optic-nerve fibre layer has degenerated. The nasal retinal lesion gave a greyish sector of degeneration (black arrows). *b*, Schematic drawing of the lesions (black spots) and retrograde degenerations of ganglion cells (hatched areas). The dashed line gives the transect from fovea to peripheral nasal retina taken to count the surviving neurons (displaced amacrine cells). *c*, Cone pedicles (bottom half) and Henle fibres (top half) in a horizontal section at 500 μm from the fovea. The plane of section through the pedicles and Henle fibres was slightly oblique. The pedicles are regularly arrayed. Close to the fovea they are elongated perpendicularly with respect to the Henle fibres, and up to an eccentricity of 3 mm they are closely packed. *d*, Vertical section through a monkey retina stained for GABA-like immunoreactivity[26]. The section was taken at 1 mm eccentricity, where the ganglion cell layer is 5–6 cell bodies thick; the unstained cell bodies can be seen in this micrograph by using Nomarski optics. Six displaced amacrine cells (arrowed) expressed GABA-like immunoreactivity. Many amacrine cells and horizontal cells stained in the inner nuclear layer (scale bar in *d* represents 3 mm in *a*, 20 μm in *c* and 50 μm in *d*).

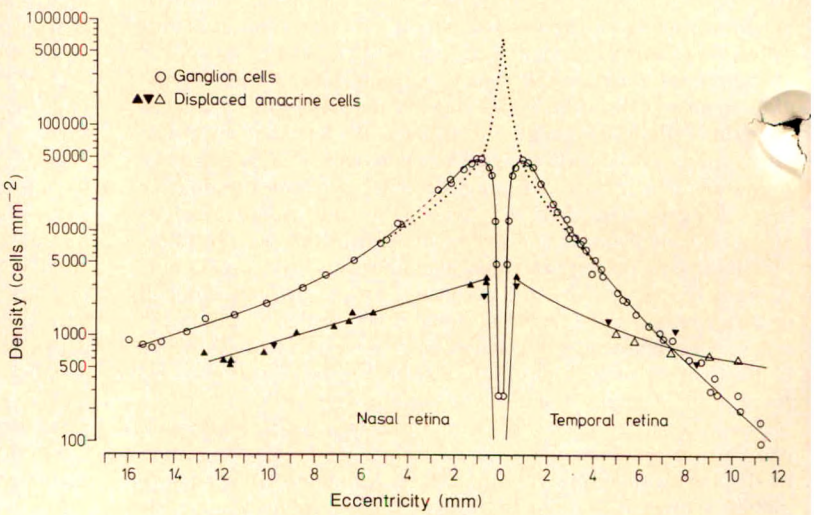

FIG. 3 Densities of ganglion cells (circles) and displaced amacrine cells (triangles) along a horizontal intersect through the macaque monkey retina. The data are corrected for shrinkage. Ganglion cell densities beyond 3-mm eccentricity were measured from Nissl-stained whole-mounts. The data in the temporal retina were measured in three retinae; those in the nasal retina are from two retinae. All neurons in the ganglion cell layer were counted. Then the density of displaced amacrine cells was substracted to give the ganglion cell densities shown. The central 3 mm represents ganglion cell counts taken from sections and corrected for shrinkage. The dotted curve, with a peak corresponding to the foveal centre, shows the sampling density of ganglion cells. By the extension of the cumulative counts (Fig. 2*f*) to successively larger circles, ganglion cell to cone pedicle ratios were calculated at increasing eccentricities. They decreased continuously from 3.34:1 in the fovea to 2:1 at 0.5–1-mm eccentricity and 1:1 at 3–4-mm eccentricity. Hence the sampling density of ganglion cells in the central retina can be derived from the cone densities of Fig. 2*a* by multiplication with the ganglion cell to cone ratios. Filled triangles (tip upwards) give densities of displaced amacrine cells in the lesioned sectors of the retina (Fig. 1*a*, *b*). A rather complete density gradient from the fovea to the nasal retina could be measured. Filled triangles (tip downwards) give densities of displaced amacrine cells, which expressed GABA-like immunoreactivity. Open triangles in the temporal retina represent counts of putative displaced amacrine cells in Nissl stained non-lesioned parts of the retina. Displaced amacrine cells in peripheral monkey retina can be separated from ganglion cells by the criteria used for the cat retina[15,16], except that closer than 5-mm eccentricity the identification of cells becomes uncertain. In three further normal monkey eyes, GABA-immunocytochemistry was performed and the essential findings of the degenerated retina were confirmed: close to the fovea, displaced amacrine cells account for ~5% of all neurons in the ganglion cell layer[32]; in peripheral retina (with the exception of the nasal retina) there are more displaced amacrine cells than ganglion cells.

can be calculated. Adding 50 μm to this radius to allow for the bipolar/ganglion cell displacement gives a circle, which includes the ganglion cells innervated by the most central 10,000 cones. Figure 2*f* shows the curves and the actual integration. In the central 300 μm of the fovea, 9,530 cones were found; in a circle of 500 μm radius around the fovea, there was about the same number of cone pedicles (9,874). The sum of all the ganglion cells in a circle of 550 μm was 33,000, which gives an average of 3.34 ganglion cells per foveal cone.

There should be two midget ganglion cells for every foveal cone, one ON- and one OFF-centre cell. When Pα and Pγ cells (20% of all ganglion cells) are considered, then at least 2.5 ganglion cells per cone must be postulated. We measured 3.34 ganglion cells per foveal cone, which makes it possible that in addition to midget cells there are other Pβ cells, which receive inputs from more than one cone.

A precise reconstruction of the fovea from serial sections was only made in the two retinae of one monkey (Fig. 2). The crucial parameters, however, which are the number of cones in the foveal centre and the ratio of ganglion cells to cone pedicles at their peaks at 750 μm eccentricity, were assessed in three additional retinae. Cone peak density substantially varied (150,000–250,000 mm^{-2}). The number of cones within the central 300-μm (Fig. 2*f*) was less variable (8,536–10,221). Both ganglion cell and cone pedicle densities peaked at 700–800 μm eccentricity, at which their ratio was 1.8 : 1–2 : 1. At smaller eccentricities this ratio was higher. Hence, although there was no reconstruction of the fovea for these three retinae, they seem to have had more than two ganglion cells for every foveal cone. Recent reports from *Macaca mulatta*[18] and from human retina[30] support this result.

Ganglion cells in more peripheral retina were counted from whole mounts. The overall ganglion cell density (corrected for shrinkage) is shown in Fig. 3. In temporal retina, from the maximum at 800 μm eccentricity, the density decreases to a minimum of 100 ganglion cells mm^{-2} at 12 mm eccentricity. The density in the nasal retina is substantially higher beyond ~2 mm eccentricity and does not fall below 800 cells mm^{-2} (ref. 11). The dotted curve in the centre of Fig. 3 gives the sampling density of ganglion cells based on the cumulative cone pedicle and ganglion cell counts (Fig. 2*e*, *f*); the density peaks at 668,250 cells mm^{-2}. A circle with a radius of 200 μm (1°) centred on the fovea is sampled by 38,000 ganglion cells; a circle with a radius of 1 mm (5°) by 220,000 ganglion cells. For comparison, the density gradient of displaced amacrine cells is shown; it changes more gradually from the centre to the periphery. Consequently, in the central retina only 5% of all neurons in the ganglion cell layer are amacrine cells, whereas in the peripheral temporal, upper and lower retina, the number of displaced amacrine cells exceeds the number of ganglion cells by a factor of five. In peripheral nasal retina, however, there are always more ganglion cells than displaced amacrine cells.

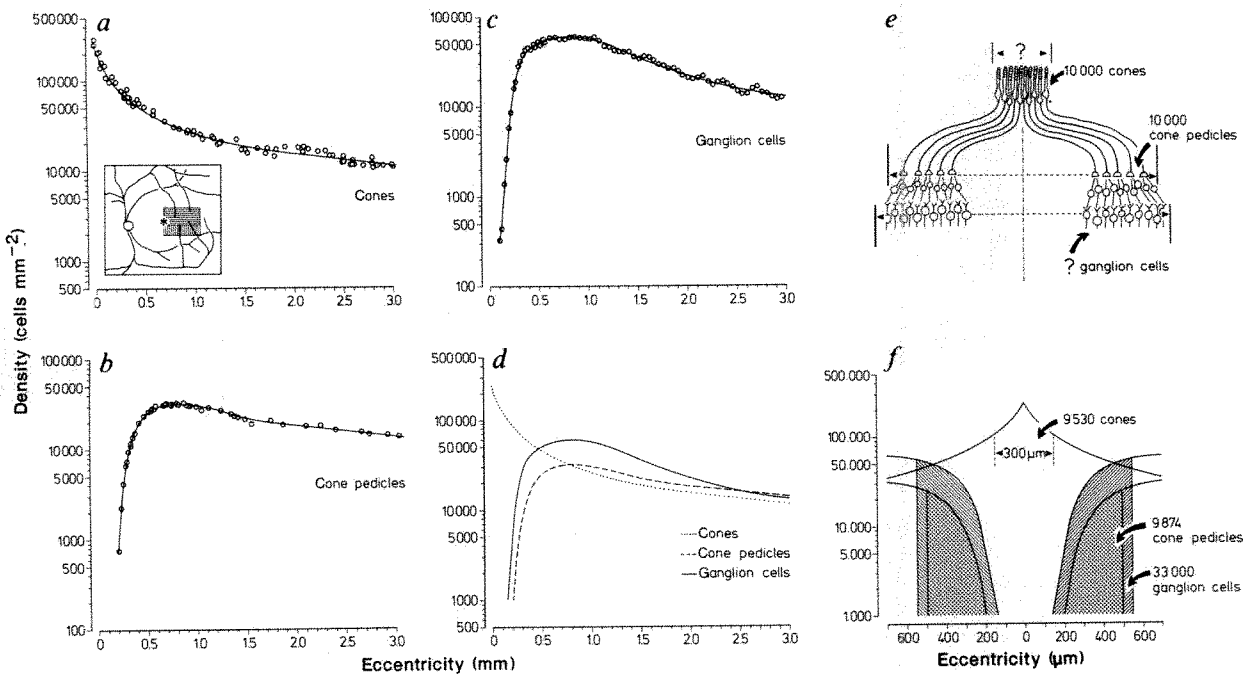

FIG. 2 Topography of the macaque monkey fovea. The inset in *a* shows the retinal area examined. The optic-nerve head (open circle), the fovea (asterisk) and some blood vessels characterize the central retina. *a*, *b*, and *c*, Cone inner segment, cone pedicle and ganglion cell densities, measured in temporal retina from the foveal centre up to 3 mm eccentricity. For the first 800 μm the curves show counts from the two sectioned retinae. In *d*, the densities of cones, cone pedicles and ganglion cells are compared. The data presented in *a*–*f* are not corrected for shrinkage. The ganglion cell to cone ratio is not affected by shrinkage, because all counts were from the same material. *e*, Schematic drawing of the monkey fovea. From the cone inner segments in the centre of the fovea, cone pedicles are displaced radially by up to 350 μm owing to the Henle fibres. In an annular zone the cone pedicles make contact with bipolar cells, which in turn synapse onto ganglion cells. *f*, Density curves of cones, cone pedicles and ganglion cells in the monkey fovea. The curves are derived from *d*, assuming radial symmetry for the foveal centre. Nasal and temporal densities did not differ within the foveal centre. The cone densities were integrated within the central 300 μm (9,530 cones), the cone pedicles were integrated in a circle around the centre of 500 μm radius (dotted area, 9,874 cone pedicles) and ganglion cells were integrated within a circle of 550 μm radius (hatched area, 33,000 ganglion cells).

METHODS. A rectangle (3.5 × 2.5 mm) was cut from the eye cup, embedded in Epon and serially sectioned at 1 μm thickness. Vertical sections (perpendicular to the retinal layers) were cut through the upper two thirds of the block, and horizontal sections (parallel to the retinal layers) through the lower one third. From the other eye of the same monkey a comparable block (2 × 1 mm) centred at the fovea was dissected out and serially sectioned vertically. Sections were stained with toluidine blue, dehydrated and mounted in Permount. Within the first 0.8 mm from the fovea, cone inner segments and cone pedicles were counted from the vertical sections of either eye; from 0.6–3 mm they were counted in horizontal sections. Ganglion cells were counted from vertical sections. The rest of the retinae were processed as whole mounts, and cone and ganglion cell densities obtained for the large eccentricities. The direct counts from the whole mounts and horizontal sections were also used to calculate a correction factor for the densities measured from the vertical sections[27]. This result was cross-checked by the disector method[28,29]. All three measurements gave results that differed by less than 10%.

Ganglion cell axons innervate relay cells in the lateral geniculate, where they remain separated in different layers corresponding to the eye of origin[9]. In the visual cortex (V1), information from the nasal retina of one eye and the temporal retina of the other are combined. The foveal representation comprises the sum of ganglion cells from both eyes (1,336,500 cells mm^{-2}). But because the nasal retina is wider than the temporal retina, at the large eccentricities only the contralateral eye is represented in the visual cortex (ganglion cell density, 800 cells mm^{-2}). If it is assumed that there is equal cortical space per ganglion cell, then it can be predicted that between the centre and the periphery the cortical representation changes by a factor of 1,670. This is in good agreement with the results of physiological studies in which 1,000–4,000-fold changes of the areal cortical-magnification factor have been reported[1–8]. On this basis it is not necessary to postulate an additional magnification in the lateral geniculate and/or the visual cortex[7,9–11]. So far, a more precise comparison between the ganglion cell density and the cortical magnification factor cannot be made on the basis of published data. The physiological measurements provide a linear magnification factor (mm of cortex per degree—often measured along only one visual axis), from which the areal magnification factor cannot be obtained if the cortical magnification is anisotropic along different axes[22,23].

In the cat visual system there is a close correspondence between retinal ganglion cell density and the decrease of the areal cortical magnification factor with eccentricity[24]. In the central area of the cat retina, the sampling density of ON-β cells is 2,000–3,000 mm^{-2}, and the cortical magnification factor is 1–4 mm^2 $degree^{-2}$ (refs 24, 25). In the monkey fovea the sampling density of ON-Pβ cells is 267,300 mm^{-2}, and the cortical magnification factor is ~ 100–300 mm^2 $degree^{-2}$ (ref. 8). Both the ganglion cell density and the areal magnification factor are 100 times those of the cat. It seems that the rules of mapping the retina onto the visual cortex are similar.

Distorted representations in the cortex are also found for other sensory modalities; the 'homunculus' of the somatotopic map on the human cortex[31] is probably the best-known example. The simple rule—that the central representation follows the peripheral receptor or neural density—may be applicable not only to the visual system but to other sensory modalities. □

Development of glomerular pattern visualized in the olfactory bulbs of living mice

Anthony-Samuel LaMantia & Dale Purves

Department of Anatomy and Neurobiology, Washington University School of Medicine, 660 South Euclid Avenue, St. Louis, Missouri 63110, USA

MANY regions of the mammalian brain are characterized by iterated ensembles of nerve cells which can be distinguished anatomically and physiologically. A particularly striking example is the pattern of glomeruli in the olfactory bulbs[1–4]; other instances are columns and 'blobs' in the visual cortex[5], barrels and columns in the somatosensory cortex[6,7], and striasomes and cell islands in the neostriatum[8,9]. Understanding the generation of these neuronal ensembles has a bearing on a variety of important neurobiological problems, including the nature of critical periods, the age-dependent response of the nervous system to injury and the manner in which neural information is stored. Analysis of these issues has usually been restricted to studies of the brains of different individuals at various ages. Many questions about the formation of such units, however, can only be answered by observing the same brain repeatedly in a living animal. This strategy would enable a direct assessment of how these units are assembled, whether the initial ensembles persist and whether units are lost or gained as an animal matures. We have succeeded in studying the pattern of glomeruli in the mouse olfactory bulb on two separate occasions during postnatal development. Comparison of the patterns observed at intervals of up to three weeks show that this part of the brain is gradually constructed by the addition of new glomeruli to a persisting population.

Glomeruli are discrete spheres of neuropile found in the outer layer of the olfactory bulbs of mammals and many other vertebrates[1,2] (Fig. 1*a*); electrophysiological and anatomical studies have shown that these units perform the initial processing of olfactory information[3,4]. To monitor their development, vital staining techniques used to explore the dynamic properties of individual nerve cells and synapses in the peripheral nervous system[10] have been adapted for use in the central nervous system. Visualizing the living brain over time, however, presents special problems. First, many salient features of neural organization are located well beneath the brain surface. Second, the dural, arachnoid and pial membranes must remain intact to preserve the integrity of the brain during the interval between observations. These membranes limit the access of vital dyes to the underlying neural elements and present a substantial impediment to microscopical imaging. Such difficulties are minimized in the mouse olfactory bulb, where the glomeruli are near the dorsal surface of the brain (Fig. 1*a*, *b*) and where the overlying membranes are relatively thin.

To observe directly how the mature pattern of glomeruli develops, 4–6-day-old mice (CF-1 strain, either sex, 2.5–3.5 g) were anaesthetized by hypothermia[11] and placed on the stage of a scanning confocal microscope[12,13] adapted for *in vivo* imaging[10,14]. To visualize glomeruli, the right bulb was exposed through a window made in the overlying bone (Fig. 1*b*), and the diffusion barrier presented by the meninges breached transiently by treatment with a hypertonic saline solution[15]. The glomeruli were then stained by applying a dilute solution of the styryl dye RH-414[16–18] to the intact dura. Within several minutes, a pattern of discrete fluorescent spheres appeared within the superficial portion of the bulb (Fig. 1*c*). Images of the fluorescently stained bulb were then digitized and stored in computer disk files. Routine histological staining (Fig. 1*d*) confirmed that each of the fluorescent spheres in these images corresponds to a glomerulus (see Fig. 2). Once the *in vivo* images had been obtained, the pups were allowed to recover and returned to the

litter after ~30 min. At intervals of 1 h to 3 weeks, a permanent histological record of the final arrangement of glomeruli was made for comparison with the initial *in vivo* images.

Images obtained in the same animal after an interval of ~1 h showed identical patterns of glomeruli (Fig. 2*a*). In eight mice examined, a total of 446 glomeruli were observed in the living state. All of these glomeruli had the same size, shape and arrangement in the final histological preparation. We saw no evidence of cryptic or nascent glomeruli that were observable with one technique but not the other. These results demonstrate that the initial visualization of glomeruli in the living animal is both complete and reliable.

At longer intervals the addition of new glomeruli was apparent. Comparison of images obtained initially and after one week showed that all of the glomeruli observed in the first image (262 glomeruli in 7 mice) could be identified in the second. However, new glomeruli were also seen, representing an average increment of 14.5% over this period. There was no evidence of glomerular elimination. After 2–3 weeks (Fig. 2*b*), the glomeruli initially observed (329 glomeruli in 9 animals) were still present. At this interval, the degree of glomerular addition had increased further, the average increment being 28.3%. The magnitude of addition of new glomeruli for each of the animals studied at these several intervals is shown in Fig. 3. This rate of addition is consistent with glomerular counts in fixed material in both mice[19] and rats[20]. Our *in vivo* observations show that new glomeruli are gradually added to a persisting population of these functional units.

Examination by light and electron microscope showed no consistent differences between the imaged and the contralateral bulbs, either acutely or after intervals of 2–3 weeks. There are, however, some inherent uncertainties in our approach. First, we cannot monitor the pattern of glomeruli continuously. Therefore, we must infer that a glomerulus in a similar position, having a similar shape, and with similar neighbour relationships at a second observation is, in fact, the same glomerulus initially observed in that location. Second, as new glomeruli are added and individual glomeruli grow larger, the relationships among the original population become progressively distorted (see Fig. 2). It is, therefore, increasingly difficult to compare the initial

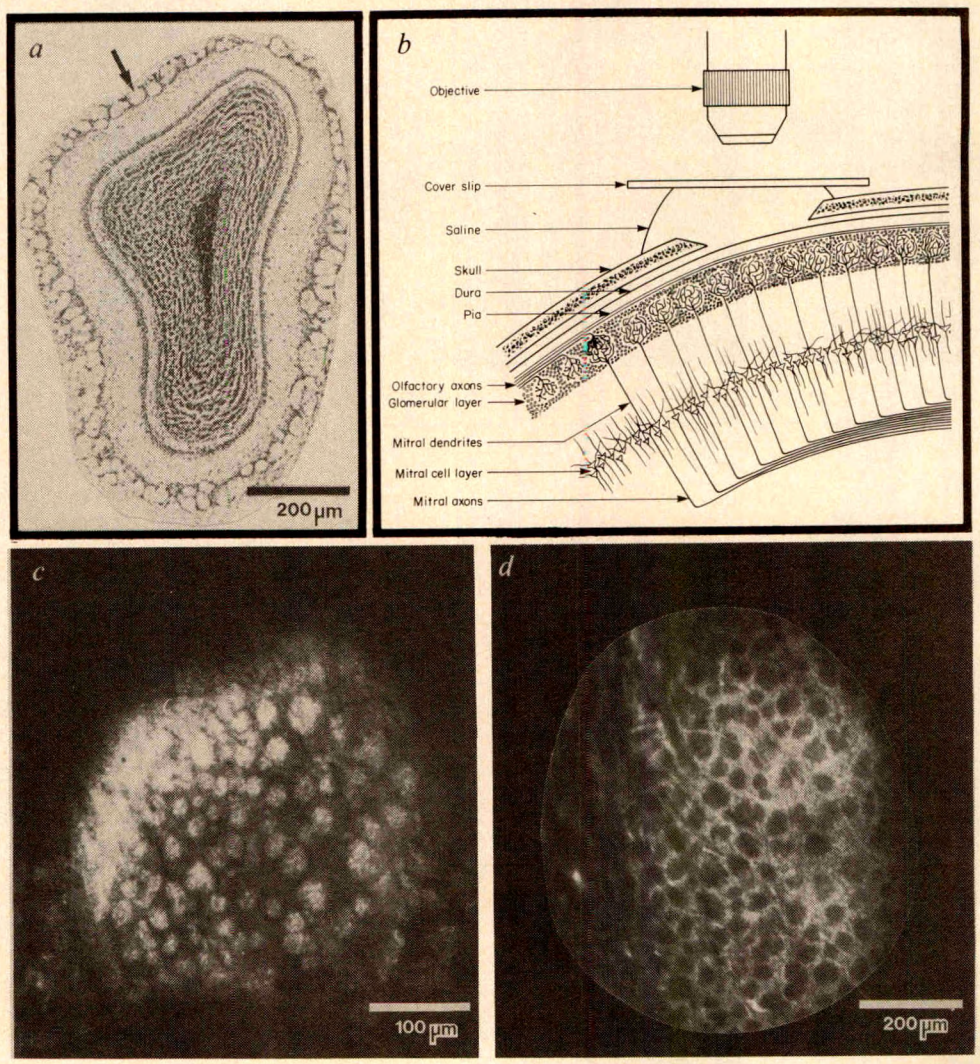

FIG. 1 Methods of visualizing olfactory glomeruli. *a*, Frontal section (50 μm) through the right olfactory bulb of a four-week-old mouse after aldehyde fixation and staining with cresyl violet (dorsal surface is up, lateral to the left). The outer layer of the mammalian bulb (arrow) comprises spherical units of neuropile called glomeruli, the borders of which are defined by a continuous rind of closely packed periglomerular cells. In the adult mouse olfactory bulb, these glomeruli number ~2,000 and, on average, measure 75 μm in diameter (S. L. Pomeroy, A-S.L, and D.P., unpublished data). The glomeruli on the dorsal surface of the bulb are generally arranged in a single layer that lies just beneath a thin mantle of afferent olfactory axons. *b*, Diagram of the surgical approach used to visualize olfactory glomeruli in the intact animal (orientation same as *a*). *c*, Confocal video image of the dorsal surface of a five-day-old mouse olfactory bulb obtained after fluorescence staining *in situ*; the bright spots are the olfactory glomeruli. In this view, anterior is up and lateral to the left. The image was obtained with an MRC LaserSharp-500 scanning confocal microscope (BIORAD), which was used to reduce out-of-focus fluorescence arising from the overlying afferent fibre layer and the meninges. The light source is an argon ion laser, fitted with 488 nm excitation and 515 nm emission filters; for each image, 25 frames were averaged using a 4× Planapo lens (numerical aperture = 0.1) at a scan rate of 1 frame per second. The depth of focus at this magnification is sufficient to image the glomerular pattern in a single plane. The laser setting was kept on low power and the intensity further reduced by a 10% transmittance neutral density filter. To stain the glomeruli, the meningeal diffusion barrier was first breached by a 3 min pretreatment with 1.8 M saline; this step was immediately followed by a 3 min exposure to a 1.5 mg ml^{-1} solution of RH-414 (Molecular Probes, Eugene, Oregon). Based on the staining characteristics of styryl dyes in the periphery[30–32], and previous descriptions of olfactory receptor axons[2,4,33,34], we surmise that many of the vitally stained elements within glomeruli are the presynaptic terminals of olfactory receptor axons. Control experiments showed that the fluorescent staining of glomeruli faded within a few hours and was not apparent 1–2 days later. *d*, Photomicrograph of the dorsal surface of the olfactory bulb stained with Sudan Black. Mice were anaesthetized with nembutal (50 mg kg^{-1}), perfused transcardially with aldehyde fixatives, and the bulbs stained '*en bloc*'. The entire bulb was immersed in a 0.7% solution of Sudan Black in propylene glycol for 10 min, differentiated by washing in propylene glycol and water and then mounted whole in gelatin. In this way we could obtain a permanent record of the glomerular pattern at any interval after the acquisition of an initial *in vivo* image.

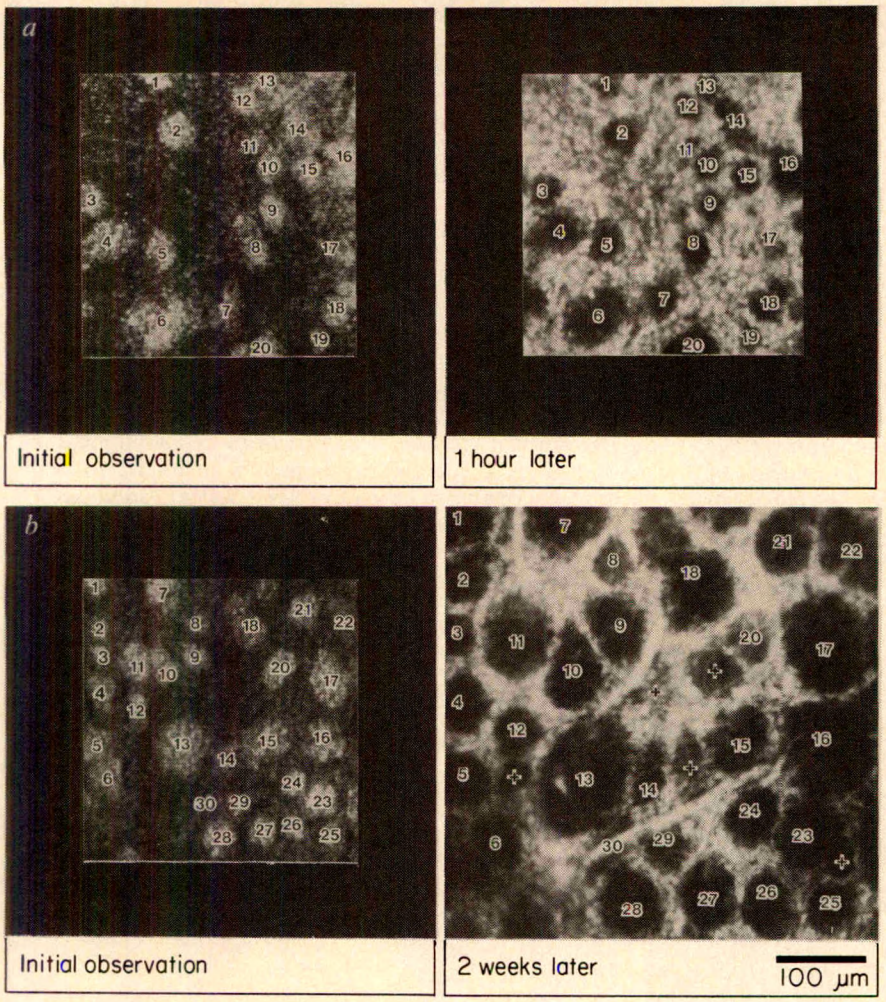

FIG. 2 Representative examples of the pattern of olfactory glomeruli observed in 4–6-day-old mice initially and after an interval of *a*, 1 h, or *b*, 2 weeks. *a* and *b* represent different animals; in each case, the left panel shows the initial image obtained *in vivo*, and the right panel the final pattern observed after staining the fixed bulb with Sudan Black. Numbers indicate corresponding glomeruli; +, indicates a glomerulus added during the interval between observations. New glomeruli were typically small compared with members of the original population; note also the substantial growth of glomeruli over the 2-week interval.

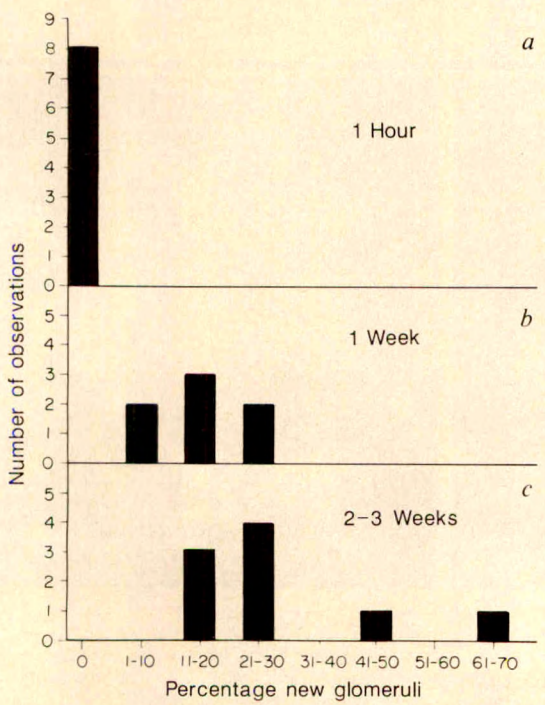

FIG. 3 Magnitude of addition of new glomeruli after intervals of *a*, 1 h; *b*, 1 week; or *c*, 2–3 weeks. Each observation represents a separate animal in which the number of new glomeruli observed in the final image is expressed as a percentage of the number of original glomeruli (all of which were retained; see Fig. 2).

and final maps with confidence at intervals of more than 3 weeks.

By monitoring the same region of the developing brain in a particular animal, we have shown that the full complement of neural circuits is not present at birth; instead, the architecture of the mouse olfactory bulb is established gradually during postnatal life by the addition of new functional units, without apparent deletions from the original population. These observations do not discount the important contribution of cell death, synaptic loss and axon elimination to the development of the brain[21–24]; they show, however, that such regressive phenomena, if they occur in this region, proceed during the ongoing construction of neural circuits. The progressive elaboration of functional units might be exaggerated in the olfactory system, which has several extraordinary features[25,26]. We note, however, that the postnatal growth of the rest of the mouse brain is approximately the same as that of the olfactory bulbs (S. Pomeroy, A.-S.L. and D.P., unpublished data). Evidence that development of at least this part of the mouse central nervous system involves ongoing construction must now be reconciled with theories that argue that brain development proceeds by the selection of useful circuits from a larger initial repertoire[27–29]. □

Positive selection of CD4$^+$T cells mediated by MHC class II-bearing stromal cell in the thymic cortex

Jerome Bill* & Ed Palmer*†‡

* Division of Basic Sciences, Department of Pediatrics, National Jewish Center for Immunology and Respiratory Medicine, 1400 Jackson Street, Denver, Colorado 80262, USA
† Department of Microbiology and Immunology, University of Colorado Health Sciences Center, Denver, Colorado 80262, USA

T LYMPHOCYTES differentiate in the thymus, where functionally immature, CD4$^+$CD8$^+$ (double positive) thymocytes develop into functionally mature CD4$^+$ helper cells and CD8$^+$ cytotoxic (single positive) T cells. The thymus is the site where self-reactive T cells are negatively selected (clonally deleted)[1–10] and where T cells with the capacity to recognize foreign antigens in association with self-proteins encoded by the major histocompatibility complex (MHC) are positively selected[11]. The net result of these developmental pathways is a T-cell repertoire that is both self-tolerant and self-restricted. One unresolved issue is the identity of the thymic stromal cells that mediate the negative and positive selection of the T-cell repertoire. Previous work has pointed to a bone-marrow-derived macrophage or dendritic cell as the inducer of tolerance[12,13], whereas a radiation-resistant[14,15], deoxyguanosine-resistant[16] thymic cell seems to mediate the positive selection of self-MHC restricted T cells. Thymic stromal cells in the cortex interact with the T-cell antigen receptor on thymocytes[17]. Using several strains of transgenic mice that express the class II MHC molecule I–E in specific regions of the thymus[18], we show directly that the positive selection of T cells is mediated by an I–E-bearing cell in the thymic cortex.

Previous experiments by MacDonald *et al.*[19] and from our laboratory (data not shown) have demonstrated that I-E expression mediates positive selection of CD4$^+$ Vβ6$^+$ thymocytes. To directly examine which thymic stromal cells are responsible for the elevated levels of Vβ6$^+$ T cells in I-E-bearing mice, we have determined the frequency of T cells expressing the Vβ6 domain in several strains of transgenic mice[18,20]. The Eα16 strain (I-Ewt) is transgenic for the $E\alpha^k$ gene and expresses the *I-E* gene product on stromal cells in the thymic cortex, thymic medulla and on B cells and macrophages. The ΔX21-16 strain (ΔX) carries an $E\alpha^k$ transgene from which the 14-base pair (bp) 'X' box in the 5′ upstream region has been deleted. In this strain there is no detectable I-E expression in the thymic cortex. There is, however, normal expression of the I-E protein on stromal cells in the thymic medulla and on B cells and macrophages. The 14-bp 'Y' box in the 5′ upstream region has been deleted from the $E\alpha^k$ transgene present in the ΔY301-54(ΔY) strain. Except for a small number of dendritic cells, I-E expression is absent from the thymic medulla of this strain. In ΔY mice, I-E is expressed on stromal cells in the thymic cortex and on 20–50% of peripheral B cells, but not on macrophages. Finally, the Sma58 strain (Sma) is transgenic for an $E\alpha^k$ gene from which a 1-kilobase (kb) fragment has been deleted from the 5′ upstream 'B-cell control' region. The I-E antigen is expressed normally in the thymic medulla and cortex but is absent from 98% of the B cells in this strain. All of these transgenes have been bred onto a B10.S(7R).βL genetic background[21]. This strain carries C57BL/10 background genes, the $H\text{-}2^{s(7R)}$ MHC (K^s, $I\text{-}A^s$, $E\beta^s$, $E\alpha^-$, D^d), and the T-cell antigen receptor (TCR) β-chain genes from C57L mice. This β-chain allele contains the Vβ1, 2, 3, 4, 6, 7, 10, 14, 15, 16 and 17a gene segments.

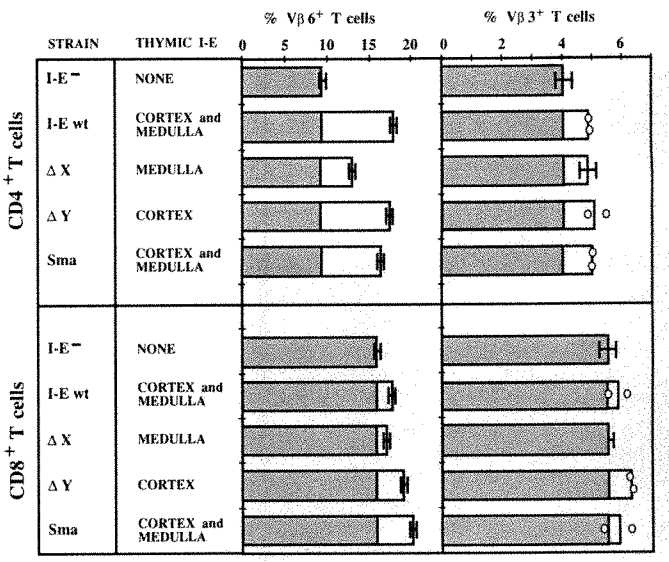

FIG. 1 Flow cytometric analysis of Vβ6-bearing peripheral lymph node T cells in transgenic mice that express I-E on various cell types. Double staining of CD4$^+$ or CD8$^+$ and Vβ6 or Vβ3 T cells is shown. Stippled portions of bars indicate the levels of Vβ6$^+$ or Vβ3$^+$ T-cells in transgenic negative (I-E$^-$) mice. I-E$^-$ mice are non-transgenic littermates.
METHODS. Lymph-node cells that were non-adherent to nylon wool were doubly stained with biotinylated RR4-7 (anti-Vβ6; ref 4) or KJ25 (anti-Vβ3; ref. 5) followed by phycoerythrin-conjugated streptavidin (Tago) and with FITC-GK1.5 (anti-CD4; ref. 28) or FITC-53.6 (anti-CD8; ref. 29) and analysed on an EPICS C or EPICS 751 flow cytometer (Coulter Electronics). Bars indicate average values from two or more individual mice; s.e.m. is given when 3 mice or more were studied, otherwise individual values are indicated by dots. The Eα 16 (I-Ewt), ΔX21-16, ΔY301-54 and Sma58 transgenes were first back-crossed onto SJL as described[18], and for this study were also back-crossed onto the C57BL/10 background by breeding to B10.S(7R)βL mice. The B.10.S(7R)βL strain carries a deletion at the TCR β-locus, which reduces the number of *Vβ* gene segments by half (refs 21, 30, 31). See text for a description of the I-E phenotypes of these strains. The increased CD4$^+$ Vβ6$^+$ level in ΔY mice compared with that in I-E$^-$ and ΔX mice is statistically significant ($P < 0.00005$). The increased CD8$^+$ Vβ6$^+$ level in ΔY mice compared with that in I-E$^-$ and ΔX mice are also significant ($P < 0.00005$ and $P < 0.0006$ respectively). Statistical significance was determined by analysis of variance with contrast using SAS (Cary).

‡ To whom correspondence should be addressed.

The data in Fig. 1 show the frequency of Vβ6-bearing T cells in these strains. $V\beta6^+$ cells account for only 9.7% of the $CD4^+$ T lymphocytes in B10.S(7R).βL ($I\text{-}E^-$) mice (non-transgenic littermates); on the other hand, 17.9% of the $CD4^+$ T cells are $V\beta6^+$ in B10.S(7R).βL mice expressing the wild-type, $E\alpha^k$ gene ($I\text{-}E$wt). The ΔY strain expresses wild-type levels of $V\beta6^+$, $CD4^+$ peripheral T cells, even though I-E expression is virtually absent from the thymic medulla, from 50–80% of the B cells, and from nearly all of the macrophages in these mice. Immunohistological staining reveals that I-E expression is normal in the thymic cortex of ΔY mice[18]. The ΔX mice do not carry wild-type levels of $V\beta6^+$, $CD4^+$ peripheral T cells and do not express the $I\text{-}E$ gene product in the thymic cortex. The Sma strain which expresses I-E normally in the thymus carries the wild-type level of $V\beta6^+$, $CD4^+$ peripheral T cells, even though I-E is not expressed on macrophages and is expressed only on 2% of peripheral B cells. Because Sma mice express wild-type levels of $V\beta6^+$ T cells, we suggest that I-E-bearing cells in the periphery have little or no role in the positive selection of the T-cell repertoire. Taken together, these results indicate that the I-E-directed, positive selection of Vβ6-bearing T cells is mediated by an I-E-expressing cell in the thymic cortex. The data in Fig. 1 show that the frequency of $V\beta6^+$, $CD4^+$ T cells in ΔX mice is increased over that seen in $I\text{-}E^-$ mice. It is conceivable that a few stromal cells in the thymic medulla have the capacity to positively select developing thymocytes, although there may not be enough of these cells to fully select the repertoire. Alternatively, large numbers of $CD4^+$ $CD8^+$ (double positive) thymocytes, residing in the thymic cortex, may not be able physically to interact with I-E-bearing cells in the medulla of ΔX mice. We would not expect a class II MHC molecule to affect the positive selection of $CD8^+$ T cells[10,22–25], but there is a significant if slight increase in the frequency of $CD8^+$, $V\beta6^+$ T cells in transgenic mice expressing I-E in the thymic cortex. These cells probably represent $V\beta6^+$ lymphocytes that have been positively selected by I-E but which inappropriately express CD8. A comparable 'inappropriate' expression of CD4 was found by Scott *et al.*[26] on 15% of idiotype$^+$ T cells in female SCID mice transgenic for a class I-restricted anti-H-Y *TCR*.

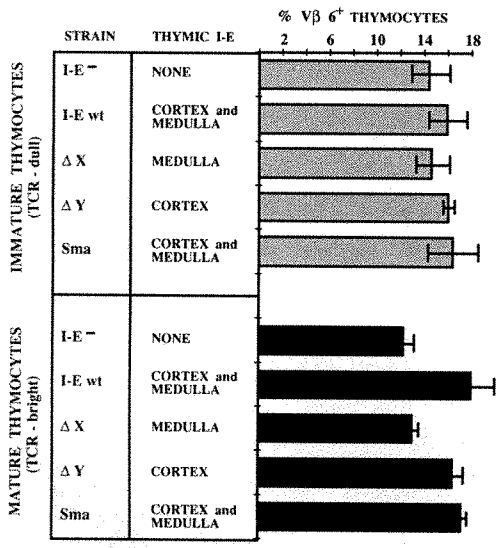

FIG. 2 Flow cytometric analysis of Vβ6 expression in I-E transgenic mice and I-E-negative littermates. Immature thymocytes (TCR-dull), stippled bars; mature thymocytes (TCR-bright), solid bars.
METHODS. Mice are described in the legend to Fig. 1. Before staining, thymocytes were cultured in complete tumour medium to increase the density of TCR on the immature population[27]. The percentage of total thymocytes displaying the immature (low-density TCR) or mature (high-density TCR) phenotypes was determined by parallel staining with H57-597, which detects all murine αβ TCRs[31,32]. Staining used biotinylated H57-597 or RR4-7 followed by phycoerythrin-streptavidin and cells were analysed as described in Fig. 1. The increased $V\beta6^+$ level in the mature thymocytes of ΔY mice over $I\text{-}E^-$ mice is statistically significant ($P<0.02$). Statistical significance was determined by analysis of variance with contrast using SAS (Cary).

It has been previously reported that Vβ17a-bearing cells are clonally deleted from I-Ewt, ΔX, ΔY and Sma mice to a similar extent. By introducing I-E expression into these animals, the level of $V\beta17a^+$ T cells decreases from 9% to 3% of the total number of T cells[18]. As the number of T cells is decreased by at least 6% in I-E-bearing animals, the fraction of all other (Vβ-bearing) T cells increases proportionately. To monitor the magnitude of this effect, we have examined the frequency of Vβ3-bearing T cells in these I-E transgenic strains (Fig. 1). Unlike the dramatic increase in $V\beta6^+$, $CD4^+$ T cells, the increase in $V\beta3^+$ T cells in I-E-bearing animals is barely detectable and is the same, regardless of the site of I-E expression in the thymus. This stands in contrast to the positive selection of Vβ6-bearing T cells, which requires I-E expression in the thymic cortex.

The data in Fig. 2 show the fraction of Vβ6-bearing thymocytes in these I-E transgenic strains. The fraction of $V\beta6^+$ thymocytes has been determined in both the TCR-dull (functionally immature, $CD4^+$ and $CD8^+$) and TCR-bright (functionally mature, $CD4^+$ or $CD8^+$) thymocyte populations[27]. The frequency of Vβ6-bearing cells among immature thymocytes is similar among all the strains we examined, regardless of whether or where the I-E gene product is expressed. Conversely, only those strains that express I-E in the thymic cortex (I-Ewt, ΔY, Sma) have an increased frequency of mature—$CD4^+$ or $CD8^+$ (single positive)—thymocytes. In agreement with the observations of others[10,23], the effects of positive selection can be seen in the mature but not the immature thymocyte population. These data are also consistent with the idea that the positive selection of thymocytes is related to the differentiation of TCR-dull ($CD4^+$ $CD8^+$-double positive) into TCR-bright ($CD4^+$ or $CD8^+$-single positive) cells.

These experiments help to identify the thymic stromal-cell type responsible for the positive selection of self-MHC-restricted T lymphocytes. Previous work has indicated that a radiation-resistant[14,15], deoxyguanosine-resistant[16] thymic cell mediates the positive selection of self-MHC-restricted T cells. Our results demonstrate that an I-E-bearing cell in the thymic cortex is important for the positive selection of $CD4^+$ T cells bearing the Vβ6 domain. The most abundant cell type in the thymic cortex is the epithelial cell, which apparently interacts with immature thymocytes to select those with specificity for self-MHC and foreign antigens. A clarification of the genetic and physiological properties of stromal cells in the thymic cortex that distinguish them from other cell types may shed light on the cellular interactions involved in the selection of a self-MHC-restricted T-cell repertoire. □

Intrathymic signalling in immature CD4$^+$CD8$^+$ thymocytes results in tyrosine phosphorylation of the T-cell receptor zeta chain

Toshinori Nakayama*, Alfred Singer*, Eric D. Hsi† & Lawrence E. Samelson†

* Experimental Immunology Branch, National Cancer Institute, and † Cell Biology and Metabolism Branch, National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland 20892, USA

THYMIC selection of the developing T-cell repertoire occurs in immature CD4$^+$CD8$^+$ double-positive thymocytes[1–3] and is thought to be mediated by signals transduced by T-cell antigen receptor (TCR) molecules and possibly by CD4 and CD8 accessory molecules as well[1,4–6]. It is not known, however, which signal-transduction mechanisms function in immature CD4$^+$CD8$^+$ thymocytes on engagement of TCR, CD4 or CD8 molecules. In mature T cells, CD4 and CD8 molecules are each associated with the *src*-like protein tyrosine kinase p56 *lck*[7,8] and signals transduced by TCR and CD4 activate tyrosine kinases that phosphorylate TCR-ζ chains and other intracellular substrates[9,10]. Consequently, we examined whether tyrosine kinases could be similarly activated in immature CD4$^+$CD8$^+$ thymocytes. Unexpectedly, we found that TCR-ζ chains from CD4$^+$CD8$^+$ thymocytes were already phosphorylated *in vivo*, and that dephosphorylation of this TCR subunit occurred on removal of CD4$^+$CD8$^+$ cells from their intrathymic environment. Rephosphorylation of TCR-ζ in cultured CD4$^+$CD8$^+$ thymocytes occurred rapidly *in vitro*, either in response to cross-linking of TCR, CD4 or CD8 by specific monoclonal antibodies, or on cell–cell contact. These observations indicate that tyrosine kinases are activated *in vivo* in immature CD4$^+$CD8$^+$ thymocytes undergoing thymic differentiation and selection. They also indicate that TCR, CD4 and CD8 molecules can function in CD4$^+$CD8$^+$ thymocytes as signalling molecules to activate tyrosine kinases and that phosphorylated TCR-ζ serves as a marker of these signalling events.

We began our studies by examining tyrosine phosphorylation levels of TCR-ζ in young-adult thymocytes. Tyrosine phosphorylation of TCR-ζ can be readily detected by immunoprecipitating intact antigen receptors from cell lysates with anti-TCR monoclonal antibodies, and then immunoblotting with affinity purified phosphotyrosine-specific antibodies[10]. We were surprised to find that TCR-ζ chains in freshly isolated thymocytes were already tyrosine phosphorylated (Fig. 1*a*, *b*), including TCR-ζ from immature CD4$^+$CD8$^+$ thymocytes (Fig. 1*c*). This latter result was obtained by immunoprecipitation with anti-Vβ17a monoclonal antibody which, in C57BR mice, binds only a small subset of immature CD4$^+$CD8$^+$ cells[11], and so a longer exposure time is required for detection than for C57L samples, where the anti-Vβ17a antibody binds to other thymocytes in addition to CD4$^+$CD8$^+$ cells[11]. The phosphoprotein observed in these immunoblots had a relative molecular mass (M_r) of 21,000 (21K) and was clearly TCR-ζ because it was directly precipitated by anti-ζ antibodies, and because it migrated under non-reducing conditions with an apparent molecular mass of 32K, a characteristic of TCR-ζ[12]. Also, the immunoprecipitation by anti-TCR monoclonal antibodies of the 21K phosphoprotein was only accomplished by anti-TCR antibodies appropriate to the strain from which the thymocytes were obtained (anti-CD3 and anti-Vβ8 monoclonal antibodies in C57BL/6 thymocytes, but not anti-Vβ17a; anti-CD3 and anti-Vβ17a antibodies in C57BR and C57L thymocytes, but not anti-Vβ8)[13].

The apparent constitutive phosphorylation of TCR-ζ in freshly isolated thymocytes indicated either that receptor-mediated tyrosine kinase activation had already occurred in these thymocytes *in vivo*, or that ζ-chain tyrosine phosphorylation had occurred for other unknown reasons. Attempts to stimulate additional thymocyte ζ-chain phosphorylation by TCR cross-linking *in vitro* failed (data not shown), indicating that phosphorylation was either already maximal or could not be induced by TCR in these cells. We then examined the effect of removing

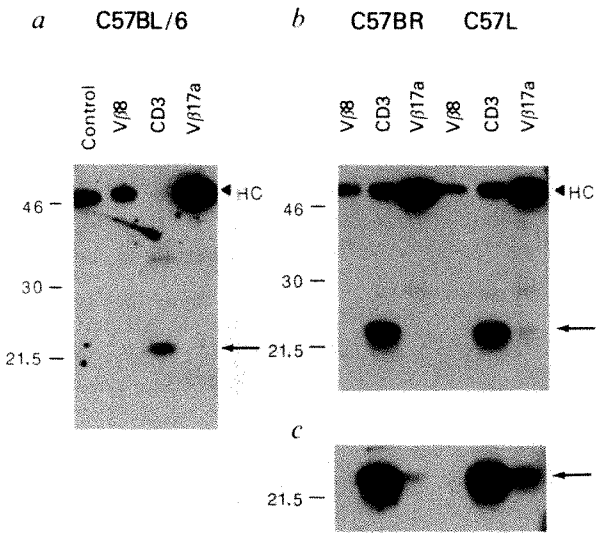

FIG. 1 Phosphorylation of the TCR-ζ chain in freshly isolated murine thymocytes. TCR from normal mice were isolated by immunoprecipitation and electrophoresis in SDS-PAGE, and tyrosine-phosphorylated TCR-ζ detected by immunoblotting with anti-phosphotyrosine antibodies. *a*, Thymocytes from C57BL/6 (H-2^b, Vβ8$^+$, Vβ17a$^-$) mice; *b* and *c*, thymocytes from C57BR/CDJ (H-2^k, Vβ8$^-$, Vβ17a$^+$) and C57L (H-2^b, Vβ8$^-$, Vβ17a$^+$) mice. The position of phosphorylated TCR-ζ chain is indicated by arrows; immunoglobulin heavy chains (HC) are also noted. Relative molecular mass markers (left) are (from the top of the gel): ovabumin (46K), carbonic anhydrase (30K), and trypsin inhibitor (21.5K). Low levels of tryosine-phosphorylated CD3-ε are seen in lanes with anti-CD3 immunoprecipitates. The 28K band immunoprecipitated with KJ23a appears to be nonspecific as it is seen in Vβ17a$^-$ cells (panel *a*).
METHODS. Thymocytes from normal adult mice were isolated, washed and solubilized to maintain intact, phosphorylated TCR–CD3 complex by a protocol using Triton X-100, protease and phosphatase inhibitors[20]. The concentration of EDTA (5 mM) in the lysis buffer is sufficient to inhibit artefactual tyrosine phosphorylation that might occur during the isolation procedure[10]. Immunoprecipitation of the TCR was performed with monoclonal antibodies absorbed to protein-A agarose. The antibodies used were: a negative control recognizing a clonotypic determinant expressed on a single T-cell clone (A2B4.2), anti-Vβ8 (F23.1) (ref. 21), anti-CD3-ε (145–2C11) (ref. 22), and anti-Vβ17a (KJ23a) (ref. 11). After immunoprecipitation, electrophoresis on a 13% acrylamide gel and electrotransfer, phosphorylated TCR-ζ chain was detected by immunoblotting with affinity-purified anti-phosphotyrosine antibodies and ^{125}I-labelled protein-A. The nitrocellulose membrane was exposed to Kodak XAR-2 film for 2 days (panels *a* and *b*) or for 2 weeks (panel *c*) at −70 °C.

thymocytes from their intrathymic environment by culturing them briefly *in vitro* at 37 °C, and observed a marked dephosphorylation of TCR-ζ (Fig. 2*a*). This dephosphorylation of TCR-ζ did not occur at 4 °C and did not reflect a general decrease in tyrosine phosphorylation of intracellular substrates induced during the short-term culture, as the amount of tyrosine phosphorylation of other substrates did not decrease (Fig. 2*a*). Consistent, therefore, with receptor disengagement and kinase inactivation, short-term culture of thymocytes resulted in preferential dephosphorylation of TCR-ζ.

We reasoned that if phosphorylation of TCR-ζ chains in freshly isolated thymocytes reflected intrathymic receptor-mediated signalling events, re-engagement of surface receptors should transduce signals that would induce the rephosphorylation of TCR-ζ. To test this prediction, we cultured thymocytes at 37 °C for various times and stimulated them for the final 30 min with anti-CD3 monoclonal antibody in the presence of Fc-receptor (FcR)-positive LK35.2 (LK) tumour cells, to induce multivalent antibody cross-linking. As seen in Table 1, TCR-ζ dephosphorylation was significant after only one hour of culture. Similarly, detection of CD3-induced rephosphorylation required only one to two hours in culture. The rapidity of these *in vitro* events indicates that TCR signalling of tyrosine kinase activation can occur in thymocytes without further differentiation and suggests that removal from the thymus results in receptor disengagement and receptor resensitization. Indeed, it is conceivable that phosphorylation of the TCR-ζ chain itself negatively regulates TCR signalling.

To assess the ability of other cell-surface molecules to induce TCR-ζ rephosphorylation, we cultured thymocytes at 37 °C overnight, and then stimulated them for 30 min with various monoclonal antibodies in the presence of FcR$^+$ LK cells (Fig. 2*b*, *c*). Anti-$\alpha\beta$TCR, anti-CD3, anti-CD4, and anti-CD8 antibodies each induced 4–7-fold increases in ζ-chain phosphorylation in whole thymocyte populations as compared with thymocytes stimulated by medium or LK cells alone, whereas anti-H-2K and anti-CD45 antibodies were either non-stimulatory or only minimally stimulatory (Fig. 2*b*, *c*). Evidence that receptor-mediated rephosphorylation of TCR-ζ specifically occurred in immature CD4$^+$CD8$^+$ thymocytes was obtained using anti-TCR reagents that selectively bind CD4$^+$CD8$^+$ cells ultimately destined for clonal elimination[11,14–17]. Stimulation of C57BR thymocytes with anti-Vβ17a[11], and stimulation of CBA/J thymocytes with anti-Vβ6[15] and anti-Vβ3 antibodies[16,17] resulted in small but significant (1.5–2-fold) increases in ζ-chain phosphorylation (Fig. 2*b*, *c*), consistent with the antibodies binding only a small subset of CD4$^+$CD8$^+$ thymocytes in these strains.

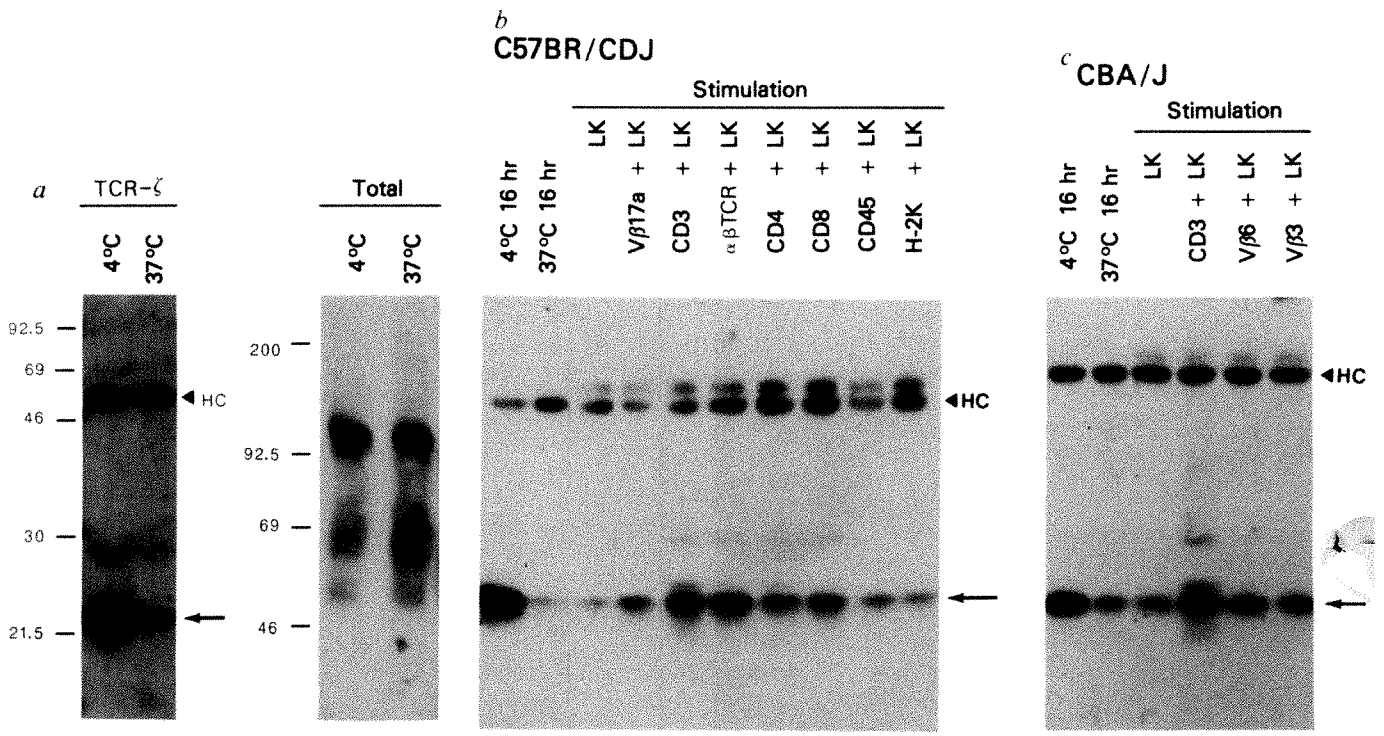

FIG. 2 Dephosphorylation and rephosphorylation of TCR-ζ chain in cultured murine thymocytes. *a*, C57BL/10 thymocytes were cultured for 16 h at either 4 °C or 37 °C. Phosphorylated TCR-ζ (left) or total tyrosine-phosphorylated molecules (right) were detected by anti-phosphotryosine immunoblotting. The level of TCR-ζ phosphorylation detected in thymocytes cultured for 16 h at 4 °C was equal to that of freshly isolated thymocytes (data not shown). Relative molecular mass markers (K) are shown on the left of each gel. *b*, Thymocytes from C57BR/CDJ (H-2^k) were cultured for 16 h at 37 °C and then stimulated for 30 min with monoclonal antibodies and a multivalent cross-linker in the form of Fc-receptor-(FcR) positive LK35.2 (LK) tumour cells[23]. The antibodies used were: anti-TCR Vβ17a (KJ23a), anti-CD3 (145-2C11), anti-$\alpha\beta$TCR (H57-597) (ref. 24), anti-CD4 (GK1.5) (ref. 25), anti-CD8 (53-6.72) (ref. 26), anti-CD45 (M1/9) (ref. 27), and anti-H-2K^k (11-4.1). The TCR-CD3 complex from the thymocytes was immunoprecipitated with anti-CD3-ε, (145-2C11). The phosphorylated TCR-ζ (arrow) was detected by immunoblotting using phosphotyrosine-specific antiserum. *c*, Thymocytes from CBA/J (H-2^k, Mls^{a,c}) were cultured for 16 h at 37 °C and then stimulated for 30 min with monoclonal antibodies and FcR$^+$ LK cells. The antibodies used were: anti-CD3 (145-2C11), anti-TCR Vβ6 monoclonal antibody (RR4-7) (ref. 28), and anti-TCR Vβ3 (KJ25a) (ref. 16).

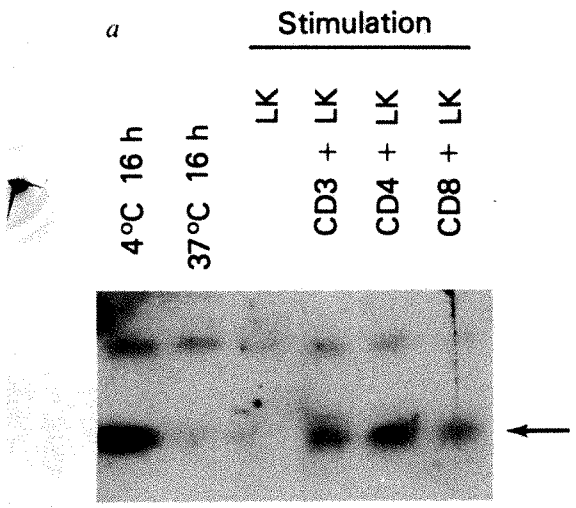
METHODS. Normal adult thymocytes (1×10^7) were cultured in 24-well culture plate (Coster 3524) in RPMI 1640 supplemented with 10% fetal calf serum at either 4 °C or at 37 °C for 16 h. In *a* (left), phosphorylated TCR-ζ was detected by immunoblotting using anti-phosphotyrosine antibodies after immunoprecipitation with anti-CD3 monoclonal antibody (145-2C11) as described in Fig. 1. Tyrosine-phosphorylated substrates in the cultured thymocytes were detected by electrophoresis of the post-nuclear lysate from 5×10^6 cells. For *b* and *c*, cultured cells (37 °C for 16 h) were stimulated with culture supernanant of monoclonal antibodies (25% v/v final concentration) in the presence of FcR$^+$ LK cells (1×10^7 ml^{-1}) at a 2:1 ratio of thymocytes to tumour cells, at 37 °C for 30 min. The TCR-CD3 complexes (3×10^7 thymocytes equivalent) were immunoprecipitated with anti-CD3 (145-2C11) and subjected to SDS-PAGE, immunoblotting and autoradiography as described in Fig. 1. Exposure times for panels *a*, *b* and *c* were 3 days, 2 days and 1 day, respectively. Relative band intensities were determined by densitometry.

To assess signalling in immature $CD4^+CD8^+$ thymocytes directly, we selected $CD4^+CD8^+$ thymocytes from whole thymus populations, obtaining cell populations that were >96% $CD4^+CD8^+$. The purified thymocytes were cultured overnight to permit TCR-ζ chain dephosphorylation, and then stimulated for 30 min with anti-CD3, anti-CD4, and anti-CD8 monoclonal antibodies in the presence of FcR^+ LK cells as a multivalent cross-linker (Fig. 3*a*). All three antibodies induced significant (2.5–3-fold) rephosphorylation of TCR-ζ (Fig. 3*a*). Control add-back experiments confirmed that the TCR-ζ rephosphorylation observed in Fig. 3*a* occurred in immature $CD4^+CD8^+$ thymocytes, and not simply in contaminating mature single-positive cells (data not shown). Thus, CD3, CD4, and CD8 cell-surface molecules are all coupled to a functional tyrosine kinase pathway in immature $CD4^+CD8^+$ thymocytes that, upon activation, phosphorylates TCR-ζ.

We next determined whether tyrosine kinase activation could occur in immature $CD4^+CD8^+$ thymocytes by direct cell–cell interactions in the absence of antibodies. LK tumour cells, which we had used in previous experiments simply as a source of FcR^+ cells during short-term stimulation with monoclonal antibodies, bear multiple MHC class I and class II molecules that are the natural ligands for CD4, CD8, and TCR. Consequently, we added LK cells for longer periods to cultures of $CD4^+CD8^+$ thymocytes in the absence of monoclonal antibodies and assessed their effect on TCR-ζ phosphorylation (Fig. 3*b*). The TCR-ζ chains from $CD4^+CD8^+$ thymocytes were far more extensively phosphorylated when LK cells were present throughout the 16-hour culture period than if they were not (Fig. 3*b*, compare lanes 2 and 3). LK cells, therefore, either inhibited the dephosphorylation of TCR-ζ in $CD4^+CD8^+$ thymocytes, which otherwise occurs during 16 hours *in vitro*, or induced TCR-ζ rephosphorylation, or both. To determine the ability of LK cells to induce ζ-chain rephosphorylation in immature thymocytes, we dephosphorylated ζ-chains, culturing for 8 hours before the addition of LK cells for an additional 8 hours (Fig. 3*b*). It can be seen that 8-hour stimulation of pre-cultured $CD4^+CD8^+$ thymocytes with LK cells induced a 3–3.5-fold increase in ζ-chain rephosphorylation (compare lanes 2, 4 and 5). Thus, cell–cell interactions, in the absence of monoclonal antibodies, can activate the tyrosine-phosphorylation signalling pathway in immature $CD4^+CD8^+$ thymocytes.

Previous studies of signalling in immature $CD4^+CD8^+$ thymocytes measured calcium transients induced by TCR engagement and found them to be present, but blunted[18,19]. The results presented here indicate that these blunted responses might be due to prior *in vivo* receptor engagement and receptor desensitization. This study also identifies activation of tyrosine kinases as a functional signalling pathway in immature $CD4^+CD8^+$ thymocytes triggered by $\alpha\beta$TCR, CD3, CD4, or CD8 molecules.

TABLE 1 Kinetics of ζ-chain phosphorylation



Time in culture (h)	ζ-Chain tyrosine phosphate*		Ratio of stimulated/ unstimulated thymocytes
	Unstimulated thymocytes†	Anti-CD3-stimulated thymocytes‡	
	Optical density§		
0	2.0	ND	
1	1.2	1.4	1.2
2	1.1	2.4	2.2
3.5	0.5	1.8	3.6

* C57BL/6 thymocytes (5×10^7) were solubilized in detergent either immediately or at the indicated times after culture at 37 °C. Intact phosphorylated TCR-CD3 complex was immunoprecipitated with 145-2C11 and subjected to SDS-PAGE, immunoblotting and autoradiography, as described in the legend to Fig. 1.

† Thymocytes (5×10^7) cultured in medium alone for the indicated time period.

‡ Thymocytes (5×10^7) were cultured in medium alone and then, for the final 30 min of culture, co-cultured with 145-2C11 culture supernatant (4% v/v final concentration) in the presence of FcR^+ LK cells at a 2:1 ratio of thymocytes to tumour cells. Total time in culture, including the 30 min anti-CD3 stimulation, was as indicated.

§ Arbitrary densitometric units.

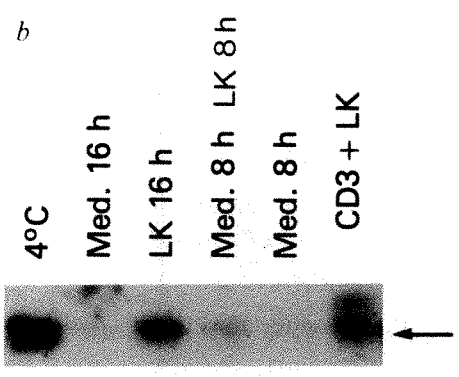


FIG. 3 Receptor-mediated signalling of tyrosine kinase activated in cultured $CD4^+CD8^+$ thymocytes. *a*, $CD4^+CD8^+$ enriched thymocytes from C57BL/6 mice were cultured at 4 °C or 37 °C for 16 h and then stimulated for 30 min with monoclonal antibodies and FcR^+ LK cells. The antibodies used were: anti-CD3-ε (145-2C11), anti-CD4 (GK1.5), and anti-CD8 (53-6.72). The tyrosine phosphorylation of TCR-ζ was detected by anti-phosphotyrosine antibodies (arrow). *b*, $CD4^+CD8^+$ enriched thymocytes from C57BL/6 mice were cultured at 37 °C for 16 h either in medium alone or together with the B-cell line, LK. Where indicated, thymocytes were cultured in media alone for 8 h and then co-cultured with LK for an additional 8 h. The phosphorylation stimulated by anti-CD3 +LK for the last 30 min of culture was also assessed as a positive control. Phosphorylated ζ-chain is indicated by an arrow. Results are representative of 3 experiments.

METHODS. $CD4^+CD8^+$ thymocytes from C57BL/6 (H-2^b, Lyt2.2) mice were enriched by applying thymocytes to anti-Lyt-2.2 (83-12-5) (ref. 29)-coated dishes (Falcon 1029) for 90 min at 4 °C. Adherent cells were collected and subjected to another cycle of anti-Lyt-2.2 panning. The anti-Lyt-2.2 monoclonal antibody used in the panning does not come off the plate and so does not interfere with subsequent staining of the cells with anti-CD8 (data not shown). The purity of the adherent cells was tested by two-colour staining using an anti-CD4 antibody (H129.19) (ref. 30) conjugated with fluorescein isothiocyanate (FITC) and a biotinylated anti-CD8 (53.6-72), followed by incubation with Texas-red-avidin.[6] The purity of $CD4^+CD8^+$ cells was >96%, with <1% contamination by $CD4^+CD8^-$ cells and <3% contamination by $CD4^-CD8^+$ cells. In *b*, 1×10^7 purified thymocytes were co-cultured with 5×10^6 LK cells in 24-well culture plate. The stimulations, immunoprecipitations and immunoblotting were performed as described in Figs 1 and 2. Exposure time was 4 days for panel *a* and 9 days for panel *b*. Relative band intensities were determined by densitometry.

Finally, we show that tyrosine kinase activation occurs *in vivo* in immature $CD4^+CD8^+$ thymocytes undergoing differentiation and selection, and that phosphorylated TCR-ζ serves as a marker of these signalling events. □

Identification of a novel retinoic acid receptor in regenerative tissues of the newt

Clifton W. Ragsdale Jr*, Martin Petkovich†, Phillip B. Gates*, Pierre Chambon† & Jeremy P. Brockes*

In urodele amphibians, the progenitor cells that regenerate amputated limbs (known as the blastema) normally replace only the missing structures[1]. After systemic delivery of retinoic acid (RA), more proximal structures are also formed, indicating that RA can control position specification in the proximal–distal axis of the regenerating limb[2–4]. According to dose and experimental context, retinoids can also re-specify the anteroposterior axis of the limb, induce deletions of skeletal elements, or block re-growth completely[2,5–10]. To study the molecular basis of these morphogenetic effects, we screened complementary DNA libraries of newt regenerative tissues (limbs and tails) for hormone nuclear receptors activated by RA[11–17]. Two functional retinoic acid receptors (RARs) were identified, one of which is the newt homologue of the human α-receptor (RARα). The second receptor, called RARδ, is novel. Sequence analysis suggests that the composite newt RAR previously reported[18] is chimaeric, consisting of 5′RAR-β-like and 3′ RARδ clones. We conclude that multiple RARs are expressed during limb regeneration in amphibians and suggest that receptor heterogeneity may underlie the different effects of retinoids on limb morphogenesis.

To identify RARs that could participate in amphibian limb regeneration, we screened an amplified newt-forelimb blastema λgt11 cDNA library with a human RARα probe[11] under low-stringency hybridization conditions. Fifty plaques out of a population of 1.2×10^6 gave positive signals and five of these were isolated and sequenced. Two of the clones, λE2 and λE3, identified the putative newt homologue of the mammalian RARα. Figure 1*a* presents the nucleotide sequence and amino-acid translation of the longest open reading frame (ORF) in λE3, which predicts a protein of 458 amino acids of relative molecular mass (M_r) of 50,638. Table 1 records the amino-acid sequence identity of the λE3 cDNA translation with that reported for the 462-amino-acid human RARα. A high degree of sequence conservation between the newt and human receptors is seen across all regions of the molecule, including regions A and F. Of particular note is that 24 of the 26 amino acids at the C-terminal end of the receptor are identical between the species, indicating that this part of the F region makes an important contribution to RAR function.

Three clones (λE1, λE4 and λE6) identified the C-terminal half of a second RAR (Fig. 1*b*). Two of these clones, λE1 and λE4, although of different size (1.5 and 3.2 kilobases (Kb), respectively), share 5′ ends, which suggests that *Eco*RI sites native to the cDNA sequence may have been cut during cloning. To obtain a 5′ extension of the sequence, we used a 164-bp *Eco*RI–*Sph*I fragment from the λE1 clone to screen a random-primed λZAP cDNA library of normal newt tail that was prepared with *Eco*RI adaptors. A single phage, λNRO, was isolated and sequenced. This cDNA overlapped the λE1 clone by 407 bp (all identical) and provided a 5′ 660-bp extension. RNase protection experiments using a 299-bp *Hin*dIII–*Pst*I fragment of this extension demonstrated that it is expressed in forelimb blastema (data not shown). These overlapping cDNA clones establish an ORF of 454 amino acids with a predicted M_r of 51,302 (Fig. 1*b*). The initiation ATG identified in Fig. 1*b* is tentative because no upstream in-frame stop codon was present in the clone, but the surrounding sequence does largely conform with that anticipated for sites of translation initiation[19]. Sequence analysis indicates that this ORF encodes a full-sized RAR, with recognizable regions A–F. We designate this RAR as RARδ.

To determine whether the two newt RAR clones could function as RA-inducible *trans*-acting factors, cDNAs corresponding to the entire ORFs of the newt RARα and RARδ were assembled in the eukaryotic expression vector pSG5 to give vectors NvRARα and NvRARδ, respectively. These expression vectors were introduced into HeLa cells in transient transfection assays that were previously employed to characterize the mammalian RARs[16], and a reporter plasmid $(TRE3)_3$-tk-CAT was used to determine *trans*-activational efficiencies. This plasmid contained an RA responsive element that controlled the expression of the gene for chloramphenicol acetyl transferase (CAT), which could be readily monitored. Both NvRARδ and NvRARα showed reproducible RA-dependent activation of the $(TRE3)_3$-tk-CAT reporter, with activity detectable at RA concentrations as low as 10^{-9} M and maximal at an RA concentration of 10^{-7} M (see Fig. 2, top). The newt receptors were much less sensitive to retinol, showing little activity at a concentration of 10^{-7} M. The vector NvRARα was as effective at inducing reporter construct activity as its human counterpart (see Fig. 2, bottom), producing 14 to 20-fold increases in reporter construct expression at 10^{-7}–10^{-6} M RA. By contrast NvRAR-δ showed lower levels of *trans*-activation (~5-fold) when exposed to these levels of RA. The basis of this difference is the CAT activity detectable in the

absence of exogenous RA in the NvRARδ transfectants (see Fig. 2).

The newt RARδ is clearly distinct from the newt RARα. First, at the nucleotide level the two receptors are only 68% identical, which is virtually the same score that is obtained when the newt RARδ is compared with the human RARα (69%). Second, genomic Southern-blot analysis of homologous regions encoding the two receptors indicates that they arise from distinct genomic locations (data not shown). Third, the pattern of expression of the two receptors is different. In normal and regenerating limbs and tails, RARα is detected as two transcripts of ~6.3 and ~7.2 kb, whereas RARδ is abundantly expressed as a major transcript of ~6.7 kb (Fig. 3).

Comparison of amino-acid sequences indicates that RARδ is closely related to the recently described mammalian γ-receptor[16,17] in regions B–E and in immediately adjoining parts of regions A and F, but that the sequence of RARδ diverges markedly from that of RARγ at the N and C termini. Comparisons between the newt and human α-receptors (Table 1)

TABLE 1 Amino-acid sequence identity of newt and human RARs

	Overall	A	B	C	D	E	F
Newt RARα							
vs human RARα	91%	76%	96%	98%	83%	97%	77%
vs human RARβ	74%	(10%)	85%	95%	80%	91%	36%
vs human RARγ	69%	(19%)	81%	95%	65%	84%	(27%)
Newt RARδ							
vs human RARα	69%	(18%)	78%	95%	67%	85%	(16%)
vs human RARβ	73%	(15%)	85%	94%	67%	90%	(13%)
vs human RARγ	82%	39%	100%	98%	78%	96%	26%
Newt RARα vs RARδ	69%	(17%)	81%	94%	70%	86%	(23%)

Amino-acid sequence identity scores are given for comparisons of the α- and δ-newt RARs with each of the human RARs (α, β and γ)[12,15,17], and with each other. Listed are calculations for the full sequences and for pair-wise comparisons for each region A–F. Scores in parentheses indicate comparisons that did not identify shared motifs (that is, runs of identical or homologous residues). vs, versus.

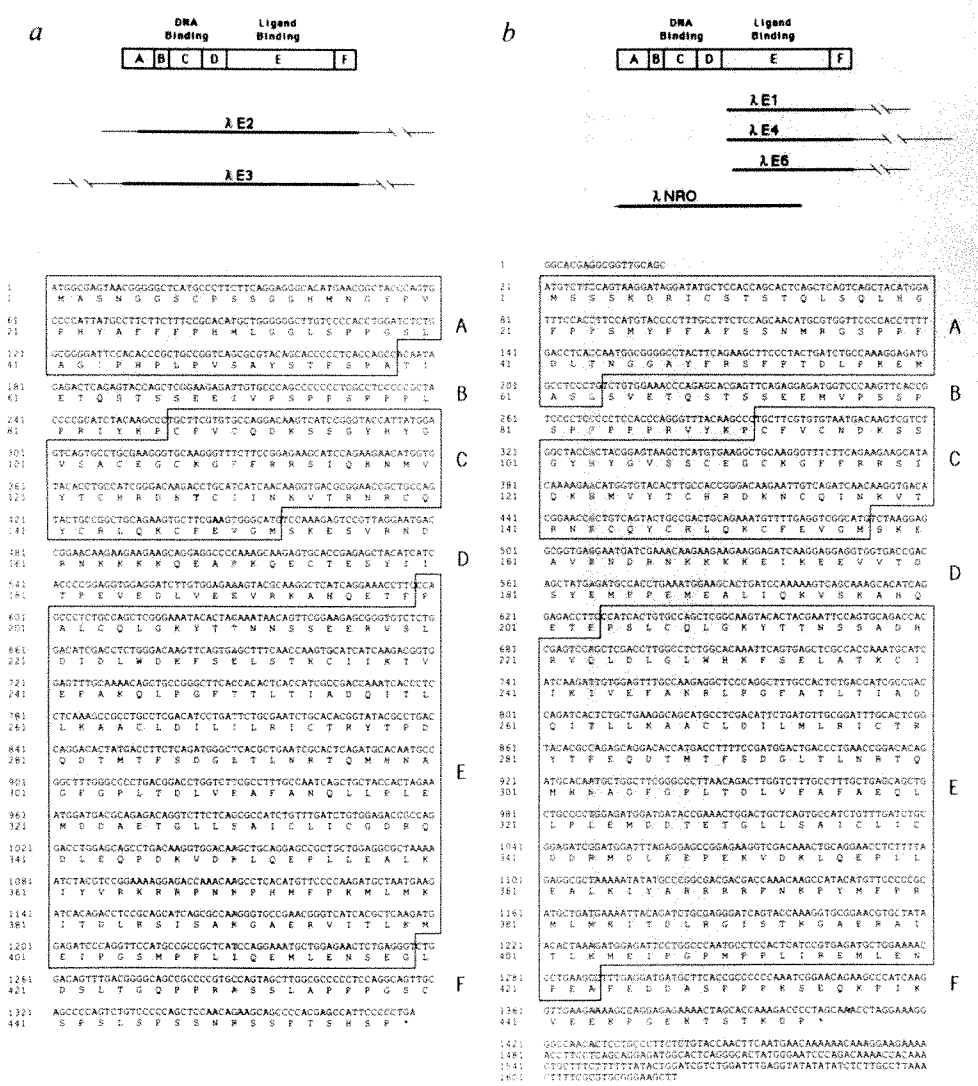

FIG. 1 Clone structure and nucleotide sequence data and predicted amino-acid sequence data for newt RARα (*a*) and RARδ (*b*). Single-letter amino-acid code is used. The cDNA's sketched at the top of the figure are aligned with a diagram illustrating the modular structure (regions A–F) of hormone nuclear receptors[26]. Region E is believed to bind to the hormone; region C is believed to bind to specific DNA sequences that are *cis*-acting hormone-responsive elements for targeted genes[26]. The N-terminal regions (A and B) are known to be important for promoter and cell-type specificity in transcriptional activation[27], but the C-terminal F region has not yet been shown to be functionally important. All six regions are indicated on the right side of the sequences and regions A, C and E are boxed. Nucleotides and amino acids are numbered on the left side of both sequences. The nucleotide sequences predicted by the cDNAs were not identical and several 'silent' polymorphisms were noted (for example a C→T substitution in the λE4 cDNA at position 1,098 of the RARδ gene sequence, which creates an *Xba*I site in this clone). *a*, Sequence of clone λE3. The λE2 sequence is as that of the λE3 clone from nucleotide 66, but an upstream termination codon in this cDNA predicts an N-terminal truncated receptor of 429 amino acids (compare with ref. 11).

METHODS. Healthy adult newts (Nv, *Notophthalmus viridescens*; Blades Biologicals, Edenbridge, Kent) were anaesthetized in a bath of 0.1% tricaine before surgery. Limbs were amputated in the middle of the upper forearm and the exposed bone and surrounding soft tissues were trimmed to produce a flat wound[28]. The newts were placed overnight in 0.5% sulfamerazine to recover. When the blastemas of the regenerating forelimbs reached the mid-bud stage (~16 days post-operatively), they were collected by amputation. Two additional rounds of tissue collection were usually possible. Tails were cut one-third to one-half the distance from their tips, and the amputated tissue was processed for normal tail RNA preparations[29]. From 1.6 μg poly(A)$^+$ RNA from forelimb blastema an oligo(dT)-primed cDNA library in the *Eco*RI site of λgt11 was provided (Clontech). A random-primed newt-tail cDNA library in the *Eco*RI site of λZAP (Stratagene) was prepared (Dr P. Savard). The forelimb blastema cDNA library was screened at low stringency with a 1,641-bp *Kpn*I–*Eco*RI fragment of the human RARα cDNA p63 (ref. 11). Hybridization was carried out over 2 days in 43% formamide, 5× SSC, 5× Denhardt's solution, 1% SDS, sodium phosphate (ph = 6.5), 200 μg ml^{-1} denatured salmon sperm DNA at 37 °C. Blots were washed for 1 h at 37 °C in 2× SSC with 0.1% SDS, dried, and exposed to Kodak XAR-5 film at −70 °C with intensifying screens. Selected positive plaques were isolated and inserts were subcloned into the Bluescribe vector (Stratagene). Hybridization for the high stringency screening of the λZAP library was carried out at 42 °C in 50% formamide, and was followed by a 65 °C wash in 0.1× SSC, 0.1% SDS. Nucleotide sequences of the cDNA subclones were determined with the dideoxynucleotide method in the Sequenase DNA sequencing kit (US Biochemical Corp.).

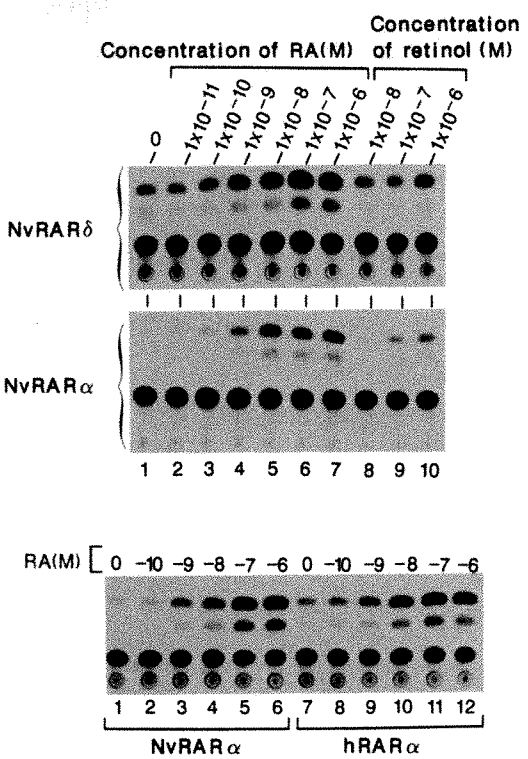

FIG. 2 Newt α- and δ-RARs function as RA-inducible *trans*-activating factors. HeLa cells were transfected with cDNA constructs of newt RARα (NvRARα), newt RARδ (NvRARδ) or human RARα (hRARα), together with the reporter plasmid $(TRE3)_3$-tk-CAT. After 24 h, the cells were fed with media that was free of retinoid (lane 0), or contained RA or retinol in the concentrations indicated in the lanes (1×10^{-11}–1×10^{-6} μ). The cells were harvested 48 h after transfection and levels of CAT activity determined.
METHODS. For the construction of the newt RARα expression vector (NvRARα), a 1.6-kb *Eco*RI–*Kpn*I fragment (pE3KR, from the clone λE3) was ligated into Bluescribe $M13^+$ vector together with a 1.6-kb *Kpn*I–*Sph*I fragment (pE3Ka), also derived from λE3. From the resulting clone, an *Eco*RI–*Cho*I fragment containing the entire newt RARα ORF was transferred into the eukaryotic expression vector PTL1 (a pSG5-based vector containing an expanded polylinker). The extensive 1.4-kb 5′ untranslated region of the resulting construct was removed by inserting an *Eco*RI linker into a *Sna*BI site located 170 bp upstream of the first methionine codon of the ORF, discarding the resulting *Eco*RI fragment and re-ligating the vector. For the construction of the newt RARδ expression vector, NvRARδ, a 1.5-kb *Eco*RI fragment from the λE1 clone (pE1) containing the 3′ half of the NvRARδ ORF was ligated into the *Eco*RI site of pSG5. The ORF was completed by inserting a 640-bp *Sac*I fragment from the λZAP clone λNRO into the *Sac*I site of the pE1 fragment in PSG5 vector. In the transient expression studies, 2 μg NvRARδ, 1 μg NvRARα or 1 μg hRARα were co-transfected into HeLa cells (grown in 90-mm dishes) together with 2 μg reporter construct $(TRE3)_3$-tk-CAT (H. de Verneuil, D. Metzger and P. C., manuscript in preparation; see ref. 16), 2 μg β-galactosidase expression vector pCH110 (Pharmacia; added to normalize transfection efficiencies), and sufficient carrier DNA (BS $M13^+$) to bring the final amount of DNA transfected to 20 μg per 90-mm dish. Transfection and retinoid treatment protocols were carried out as previously described[11,14,16], except that 50 OD_{420} units of β-galactosidase activity were used for the CAT assays shown for NvRARδ transfections, whereas 20 OD_{420} units were used for the NvRARα and the hRARα transfections.

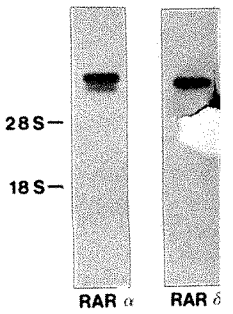

FIG. 3 Northern-blot analysis of the distribution of newt RARα and RARδ transcripts. Illustrated is a blot of poly(A)$^+$ RNA from normal forelimb probed first for RARα (14 days exposure) and then for RARδ (9 h exposure). Similar transcription patterns were observed with forelimb blastema and normal and blastemal tail preparations. The positions of newt 28S and 18S rRNA are indicated on the left.
METHODS. Total RNA was extracted by homogenization in 4M guanidine thiocyanate[30] and then by centrifugation in phenol–chloroform, and poly(A)$^+$ RNA was selected by one or two passages over an oligo(dT) column[31]. Samples of 3–8 μg mRNA were run on an agarose-formaldehyde gel and transferred to GeneScreen (NEN)[29]. A 1.6-kb NvRARα *Kpn*I–*Sph*I fragment (pE3Ka; includes ~0·6 kb of 3′ untranslated sequence) and the 939-bp NvRARδ *Eco*RI–*Hinc*III fragment (pE1c) were chosen as probes. Fragments were radiolabelled by random priming (BCL), and hybridizations were carried out overnight at 42 °C in 50% formamide, 1 M NaCl, 5× Denhardt's solution 2% SDS, 10% dextran sulfate, 50 mM Tris-Hcl (pH = 7.5), 200 μg ml^{-1} denatured salmon sperm DNA. Blots were washed at 65 °C in 0.1× SSC, 2% SDS for 1 h and exposed to Hyperfilm (Amersham) with intensifying screens. Hybridized probe was stripped from blots before being used again in 96% formamide, 10 mM Tris-HCl (pH = 7.5), 10 mM EDTA for 30 min at 60 °C.

and between the mouse and human γ-, β- and α-receptors[17] strongly suggest that if RARδ is the newt homologue of RARγ, then the sequence throughout regions A and F should be highly conserved. The presence of shared short runs of amino-acid sequence between RARδ and RARγ in regions A and F is insufficient to demonstrate homology, given that the mammalian α- and β-receptors share a Ser-Pro-Ser-X-Ser-Pro-Ser-Ser amino-acid motif in the F region. Although clear resolution of this issue depends on the successful identification of a newt RARγ, the structural similarity of RARδ and RARγ does raise the possibility that these receptors form a subclass of RARs that is distinguisable from the subclass that includes α- and β-receptors. In particular, the observation that the amino-acid sequence of the C1 region (which confers sequence specificity in DNA binding to target hormone-responsive elements[20,21]) is identical for RARα and RARβ, and for RARγ and RARδ, but differs by 2 out of 31 residues between RARα/β and RARδ/γ, indicates that δ- and γ-receptors could share a selectivity for natural hormone-response elements that is different from that of α- and β-receptors.

The presence of a functional RAR in the regenerating newt limb was recently reported[18]. The sequence of this receptor was based on two non-overlapping cDNA clones, isolated from a hindlimb blastema library, that were juxtaposed at an *Eco*RI site. The 3′ clone, λNB6, covers most of the E region, the F region and a considerable extent of 3′ untranslated sequence. In its translated region, the λNB6 cDNA is 98% identical at the nucleotide level with our RARδ clones and differs at only 2 out of 240 residues in predicted amino-acid sequence, indicating that it identifies the RARδ. The 5′ clone[18] λNB8, which covers a part of the A region, regions B–D and a part of region E, is only 75% identical in nucleotide sequence with our RARδ cDNA extension, λNRO. At the predicted amino-acid level, λNB8 is closer to the human RARβ (96% identity) than to the newt RARδ (79%) or the newt RARα (84%), and shows identity scores wth the human RARβ in regions B, C and D of 100%, 98% and 91%, respectively (compare with Table 1). We conclude first, that the composite receptor reported[18] is a chimaera, made up of RARδ and RARβ-like cDNA clones; and, second from *in situ* hybridization experients using part of the λNB8 clone[18], that the newt limb blastema expresses a RARβ-like RAR.

The multiple patterning effects produced by RA treatment of regenerating limbs (that is, proximal–distal and anterio–posterior axis re-specification as well as teratogenic-like deletions and complete inhibition of regeneration[22,23]) is consistent with the presence of at least three distinct RARs (α, δ and β-like) in limb blastemas. The challenge is to identify which receptors can control axis specification, and to determine whether a particular axis is governed by a unique RAR. Functional analysis of the receptors present in the blastema will be assisted by studies of their distribution and affinity for RA[24], and

examination of the effect of manipulating their expression in cultured blastemal cells that are subsequently introduced into regenerating limbs[25]. □

Transactivation of the *Xenopus* rRNA gene promoter by its enhancer

Marietta Dunaway & Peter Dröge

Department of Molecular and Cell Biology, University of California, Berkeley, California 94720, USA

A KEY question concerning the mechanism of transcriptional activation by enhancers is about the role of the DNA that connects the enhancer to the promoter[1-3]. The linking DNA will be important if a regulatory protein(s) binds to the enhancer and then tracks or slides along the DNA to the promoter, or if, on binding, the protein(s) alters the topological state of the DNA. By contrast, if the linking DNA loops out to allow the formation of a promoter–enhancer complex, or if the enhancer increases the local concentration of a transcription factor, co-linearity of the promoter and the enhancer will not be strictly required. In *Xenopus laevis*, the transcription of the ribosomal RNA genes is stimulated by an enhancer composed of repetitive sequences in the intergenic spacer regions[4,5]. These repetitive elements contain 60 or 81 base pairs, and their activity is relatively independent of their position and orientation[6-8]. When the enhancer and promoter sequences are each located on separate DNA molecules, however, the enhancer is no longer able to augment transcription[8]. We have now tested whether or not this apparent requirement for having the enhancer and promoter in *cis* can be overcome by keeping them in close proximity while locating them separately on different molecules. This was achieved by generating multiply intertwined, dimeric catenanes in which the enhancer and promoter were located in *trans* on different rings. By injecting these catenanes into frog oocytes and measuring the activity of the enhancers in a series of competition assays, we were able to demonstrate that such enhancers can augment transcription *in vivo*.

Dimeric catenanes have been used successfully to study how distant protein-binding sites interact during recombination[9,10]. We constructed a plasmid, pPD40E, that contained directly repeated sites for recombination by phage λ integrase, a rRNA minigene and an enhancer module of 10 repetitive elements (Fig. 1*a*)[5,8,11]. In this plasmid the enhancer is located ~3.7 kilobases (kb) from the promoter. To obtain multiply intertwined catenanes in which the enhancer and the promoter are located separately on different DNA molecules, we recombined pPD40E *in vitro* by using phage λ integrase, and the catenated material was separated from the unrecombined plasmid by electrophoresis (Fig. 1*b*)[12,13]. In plasmid pXlr401, the enhancer is in its normal position and orientation relative to the promoter (Fig. 1*c*).

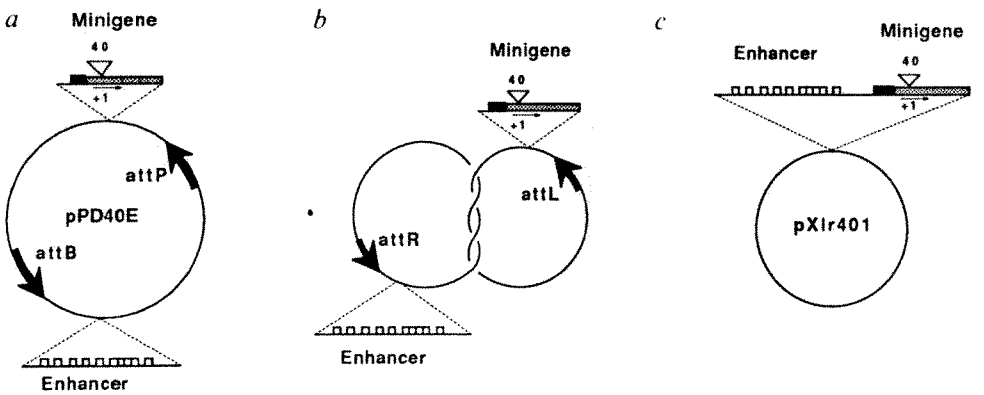

FIG. 1 Constructs used to test transactivation by the rRNA-gene enhancer. *a*, Plasmid substrate for site-specific recombination *in vitro* is pPD40E. The enhancer (open boxes) is near the *attB* site and the ψ40 minigene is near the *attP* site. The minigenes in pPD40E, pPDψ40, and pXlr401 contain an insert of 40 bp (open triangle) to distinguish their transcripts from the endogenous rRNA transcripts. The minigenes in pPDψ52 and pXlrψ52 contain 52-bp inserts so that transcripts from competing templates can also be distinsuished. The black boxes represent the rRNA-gene promoter; the gene body (stippled box) is a fusion between the first 115 bp of the rRNA transcript with the final 200 bp of the 28S portion of the gene. The recombination sites are represented by black arrows. The distance between enhancer and promoter in pPD40E is ~3.7 kb. *b*, Recombination of pPD40E *in vitro* using phage λ integrase and *Escherichia coli* integration host factor was performed as previously described[11,12]. After recombination, the mixture of negatively supercoiled catenanes was electrophoresed in a 0.8% high-resolution agarose gel, which separates the recombined catenanes from residual unrecombined plasmid[22]. The catenanes were isolated from the gel and prepared for injection using standard methods. *c*, Plasmid pXlr401[8] contains ten 60- or 81-bp repeats in their normal position and orientation, and the insert is cloned into pUC19. METHODS. Construct pPD40E was prepared from pAB7.0d, pXlrψ40 and pXlr14F[5,8,11]. The vector pAB7.0d was modified to contain single restriction sites for *Eco*RI and *Kpn*I by eliminating one of the two *Eco*RI sites and by introducing a *Kpn*I site at one of the two *Nde*I sites. The inserts derived from pXlrψ40 (minigene) and pXlr14F (enhancer) had linkers added as needed and were inserted as *Eco*RI or *Kpn*I fragments, respectively. The related plasmids pPDψ40 and pPDψ52 contain only the minigenes ψ40 and ψ52, respectively, which were inserted into pAB7.0d at the same position as the minigene in pPD40E.

The principle of the competition assays is as follows. Frog oocytes are co-injected with two different plasmid DNAs[4,5]. Each of the plasmids carries a rRNA minigene that contains an insert of either 40 or 52 (base pairs bp) (Fig. 1). The injected templates compete for a pool of transcription factors. This results in the production of transcripts, which, because of their different-sized inserts, can be biochemically distinguished from each other and from endogeneous rRNA. This is achieved by using S1 probes specific for each of the two different transcripts that originate from the competing templates[14]. When one of the plasmids contains an enhancer, the activity of the enhancer can be expressed as the ratio of the transcripts originating from the enhancer-containing plasmids to those originating from the plasmids devoid of enhancers[5]. The competition assay thus provides an internal control for variations in the injection technique and for the recovery of RNA from the injected oocytes.

Figure 2*a* shows the results of one such assay in which the enhancer catenated to the promoter was used. For every experiment, we co-injected the two minigenes in equal amounts to provide a control for differences in the specific activities of the S1 probes (lanes 1*a* and 1*b*). In experiment 1, the probe specific activity for the transcript with the 52-bp insert (pXlrψ52) was about fourfold that for the 40-bp insert transcript (lanes 1*a* and 1*b*). Injection experiments in which the two minigenes were inserted into the plasmids pBR322, pUC19 and pAB7.0d indicate that neither vector sequences nor plasmid size affects the activity of the rRNA promoter in the competition assay (data now shown). A 70-fold transcriptional advantage was conferred on plasmids with enhancer sequences in their normal position and orientation over those that contained a minigene only (lanes 2*a* and 2*b*). The unrecombined plasmid pPD40E, in which the enhancer was ~3.7 kb away from the promoter, showed a sixfold greater transcriptional activity than a promoter alone (lanes 3*a* and 3*b*). In the purified catenanes, no unrecombined plasmid was detected (Fig. 3, lanes 4 and *C*). Co-injection of the purified enhancer–promoter catenanes with a plasmid containing only the promoter led to an eightfold higher transcriptional activity of the catenanes than of the normal plasmids (Fig. 2*a*, lanes 4*a* and 4*b*). Catenation is required for the effect because co-injection of an uncatenated enhancer with the two minigenes does not affect the transcriptional ratio between them (compare lanes 1*a* and 1*b* with lanes 5*a* and 5*b*).

To exclude the possibility that the activation observed in the catenated promoter–enhancer results from an undetectable amount of unrecombined pPD40E, we added unrecombined pPD40E to the mixture of plasmids that we used in the experiments shown in Fig. 2*a* (lanes 5*a* and 5*b*). The addition of pPD40E at ~5% the concentration of the other plasmids did not significantly change the ratio of the two transcripts to one another (compare lanes 5*a* and 5*b* with lanes 6*a* and 6*b*), yet the added pPD40E was detected on the Southern blot (Fig. 3, lane 6). It is improbable, therefore, that the transcriptional activation observed with the catenated enhancer was due to a small amount of undetected templates that had the enhancer in *cis* with the promoter. Although previous experiments have shown that there is no detectable difference in the transcriptional activity of supercoiled, nicked or relaxed templates injected into oocytes[15], it is also formally possible that the topology of catena-

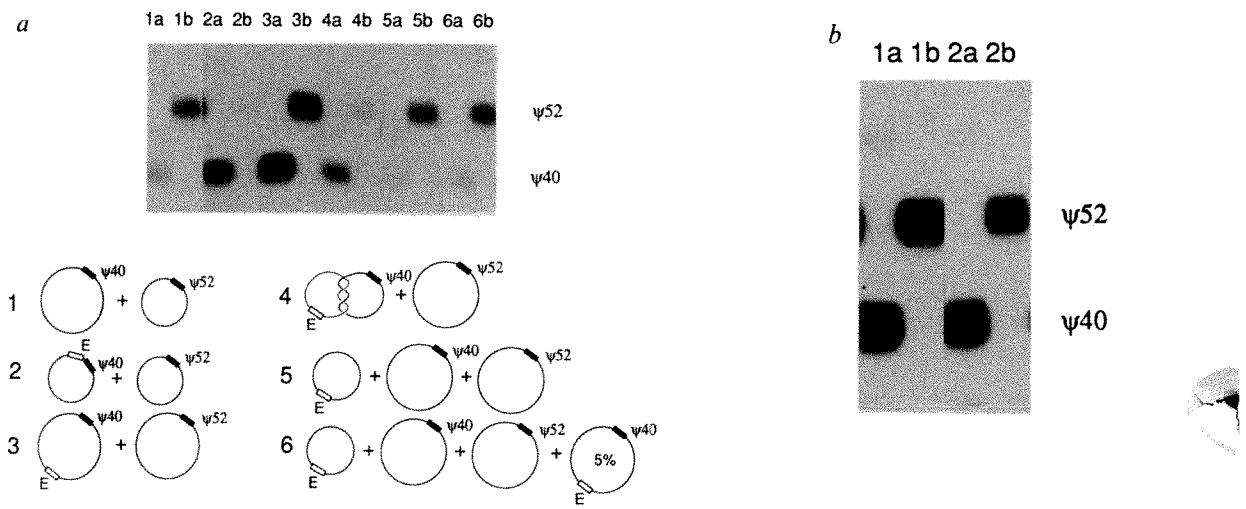

FIG. 2 Transcription of promoter–enhancer catenanes injected into *Xenopus* oocytes. *a*, As illustrated below the autoradiograph, injection mixtures are: (1), pPDψ40 + pXlrψ52 (2), pXlr401 + pXlrψ52 (3), pPD40E + pPDψ52 (4), pPD40E-catenanes + pPDψ52 (5), pPDψ40 + pPDψ52 + pXlr14F (6), reconstruction containing the mixture of plasmids used in lane 5 plus 5% added unrecombined pPD40E. *b*, In a separate experiment, catenanes of pPDψ40 were prepared and injected in competition with pPDψ52. The specific activities of the S1 probes in this assay were approximately equal. 1, pPDψ40 catenanes + pPDψ52; 2, unrecombined pPDψ40 + pPDψ52.

METHODS. DNAs were quantitated before injection by electrophoresis on agarose gels, ethidium bromide staining, and scanning of photographic negatives using a Hoefer densitometer. A solution (~20 nl) containing 500 pg of each competing template and 50 μg ml^{-1} α-amanitin was injected into each oocyte nucleus. Between 50 and 60 oocytes were injected with each sample. Transcripts were allowed to accumulate overnight, and the surviving oocytes (80% or more) were collected and pooled the next day. The oocytes were homogenized in a buffer containing 1% SDS, 100 mM NaCl, 50 mM Tris-HCl, pH 7.8, 20 mM EDTA and 0.1 mg ml^{-1} proteinase K. The mixture was incubated at 37 °C for 30 min, extracted in phenol and the nucleic acids precipitated with ethanol. The precipitate was resuspended in 10 μl sterile TE (10 mM Tris-HCl, 1 mM EDTA, pH 7.3) buffer per oocyte and used in all subsequent assays without further purification. Single-stranded, end-labelled probes that are specific for the transcripts of each of the two competing templates were prepared and hybridized in individual reactions with an equivalent of 5 oocytes from each sample[14]. After hydridization, the samples were treated with S1 nuclease, and the reaction was stopped by addition of excess EDTA. After precipitation with ethanol, the DNA was run on an 8% acrylamide–7M urea gel. The gel was dried and exposed to preflashed Kodak XAR film[23]. The final transcriptional ratios from competing templates were calculated as follows: Appropriate autoradiographic exposures of the gel were scanned to obtain uncorrected values for each transcription signal. Autoradiographs of the Southern blot in Fig. 3 were also scanned to determine the relative concentrations of competing templates. The transcription signals are then normalized to a template ratio of 1:1; if DNA is less than 5 ng, the transcriptional signal is proportional to the template concentration[24]. From this information, the relative specific activities of the S1 probes can be determined from the injection of the two promoters. The transcription results are then corrected for differences in probe specific activity to calculate the transcription ratios stated in the text. Lanes labelled as '*a*' were assayed with the ψ40 probe, and lanes labeled as '*b*', with the ψ52-specific probe.

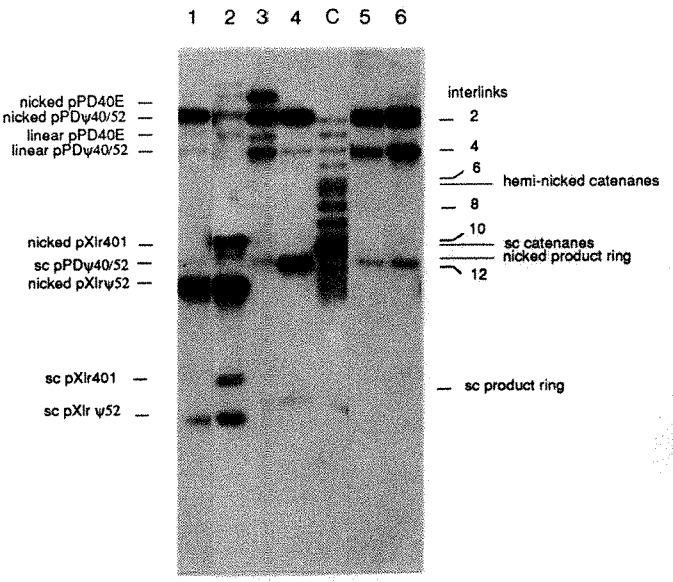

FIG. 3 Template analysis of the injected DNAs. Total nucleic acid from the equivalent of two injected oocytes was nicked by reaction with DNase I in the presence of 500 $\mu g\ ml^{-1}$ ethidium bromide. The samples were extracted in phenol, and an aliquot (1/3 oocyte) was electrophoresed as described[22]. The gel was blotted and probed with a fragment containing the $\psi 40$ minigene. This probe will hybridize equally well with plasmids containing either the $\psi 40$ or $\psi 52$ minigene. The blot was exposed to film without using intensifying screens, and bands were quantitated by densitometry. Lane numbers correspond to those in Fig. 2*a*. Lane C, catenanes before injection; sc, negatively supercoiled.

tion *per se* could be responsible for the transcriptional activation of a promoter. To exclude this possibility, we prepared catenanes of a minigene without an enhancer by recombination of pPDψ40 *in vitro* and injected them in competition with unrecombined pPDψ52. Catenation did not change the ratio of the two transcripts (Fig. 2*b*).

Our results show that the enhancer for the rRNA minigene is not strictly required in *cis* with the promoter and can augment transcription when catenated to a promoter. We repeated the experiment four times and observed transactivation by the catenated enhancer in three experiments. In all cases, the level of enhancement was the same or higher than that observed with unrecombined pPD40E.

In the oocyte injection experiments, 18–20 hours elapsed between the injection of templates and the preparation of RNA. To assess both the extent of decatenation and the actual ratios of co-injected templates, the injected DNA was analysed by gel electrophoresis and Southern blotting. The catenanes contained between 2 and 12 interlinks before injection, and there was no detectable unrecombined plasmid (Fig. 3, lanes 4 and C). All of the interlinks were removed during an overnight incubation of the injected oocytes, however, so that only free-product rings were detected. A more detailed analysis of the kinetics of decatenation *in vivo* showed that this process is rapid and completed within 20–30 minutes after injection of catenanes (data not shown).

Because the *Xenopus* rRNA-gene enhancer can augment transcription in *trans*, enhancer models that invoke a protein-tracking mechanism or a DNA conformational change that is propagated through the linking DNA are ruled out. Models that are compatible with our results include the formation of a complex between the enhancer and promoter by looping, and the attachment of the enhancer to cell structures that mark active genes. But because the same transcription factor acts at both the promoter and the enhancer[25], the rRNA-gene enhancer may work by increasing the local concentration of this factor in the vicinity of a promoter[16]. If this is so, then the transcription factors could locate the promoter either by the looping out of the linking DNA or by three-dimensional diffusion.

The observation that the catenanes are completely resolved into product rings within 30 minutes of injection but are able to augment transcription, places further constraints on the viable models of enhancer action. Enhancement must occur rapidly after injection. It is possible that a complex between the promoter and enhancer is formed by protein–protein interaction, after which the two DNA rings can be unlinked without disrupting the enhancer–promoter complex. The rapid decatenation is also consistent with a requirement for the enhancer only during the initial activation of the gene. Experiments showing that enhancers can also function within the transcription unit further support the idea that the enhancer may only be required transiently[14]. The increasing evidence that RNA polymerases can transcribe through protein-bound DNA[17–20], however, suggests that the internal enhancer could still be part of a stable enhancer–promoter complex. Furthermore, the enhancer found in the intron of the immunoglobulin gene is required at least every cell cycle, and possibly continuously, for the expression of the gene[21]. Although our experiments do not distinguish these possibilities, we favour the formation of a stable promoter–enhancer complex. □

RNA editing in wheat mitochondria results in the conservation of protein sequences

José M. Gualberto, Lorenzo Lamattina, Géraldine Bonnard, Jacques-Henry Weil & Jean-Michel Grienenberger*

RNA editing is a process that results in the production of a messenger RNA with nucleotide sequences that differ from those of the template DNA[1], and provides another mechanism for modulating gene expression. The phenomenon was initially described in the mitochondria of protozoa[2,3]. Here we report that RNA editing is also required for the correct expression of plant mitochondrial genes. It has previously been proposed that in plant mitochondria there is a departure from the universal genetic code[4], with CGG specifying tryptophan instead of arginine. This was because CGG codons are often found in plant mitochondrial genes at positions corresponding to those encoding conserved tryptophans in other organisms. We have now found, however, wheat mitochondrial gene sequences containing C residues that are edited to U residues in the corresponding mRNA sequences. In this way, CGG codons can be changed to UGG codons in the mRNA so that tryptophan may be encoded according to the universal genetic code. Furthermore, for each codon modification resulting from a C → U conversion that we studied, we found a corresponding change in the amino acid that was encoded. RNA editing in wheat mitochondria can thus maintain genetic information at the RNA level and as a result contribute to the conservation of mitochondrial protein sequences among plants.

Although it was proposed that in plant mitochondria CGG codes for tryptophan instead of arginine, no transfer RNA specific for tryptophan and recognizing CGG, or a gene for such a tRNA, has been found in plant mitochondria[5]. Moreover, the wheat mitochondrial genes *nad3*, *rps12* (ref. 6) and *cox3* (J.M.G., C. Domon, J.-H. W. and J.-M.G., manuscript in preparation) contain CGG codons corresponding to positions in their encoded amino-acid sequences that are conserved as either tryptophan or arginine residues. The recent characterization of a non-genomically encoded U at the junction of two exons in wheat *nad4* mRNA (L.L., J.-H.W., J.-M.G., manuscript submitted) showed that RNA editing can also exist in plant mitochondria. This encoding could result either from the addition of a U or from a C → U conversion. If such a C → U conversion affects a CGG codon, then the codon will be changed to UGG, which specifies tryptophan. To test whether this is occurring, we deduced the mRNA sequences corresponding to selected regions encompassing CGG codons of the wheat mitochondrial *nad3*, *rps12* and *cox3* genes. This was achieved by sequencing uncloned complementary DNAs that were primed by specific oligonucleotides, using total mitochondrial (mt) RNA as a template (Fig. 1). The CGG codons of *rps12* and *cox3*, which code for conserved arginines (positions indicated in Fig. 1) remain CGG codons at the RNA level. In *cox3*, however, the CGG codon located at a position corresponding to a conserved tryptophan is replaced by a UGG codon in the deduced mRNA sequence (Fig. 1). At a position in the *nad3* cDNA sequence that corresponds to a genomic CGG and a conserved tryptophan, either GCC or ACC is found. This ambiguity could not be resolved by using different RNA preparations as templates. The *nad3* mRNA seems, therefore, to exist as two distinct species, which have either CGG or UGG codons. This could be due to the presence of both unmodified and modified transcripts. We used the same approach to determine the cDNA sequence of regions of the wheat mitochondrial *cox1* (ref. 7), *cox2* (ref. 8) and *cob* (ref. 9) genes where CGG codons are present (Fig. 2). The results show that the three CGG codons of *cox2* and the two CGG codons of *cob* (all located at positions corresponding to conserved tryptophan residues) are all converted to UGG codons in the mRNAs. The only CGG of *cox1*, which corresponds to a non-conserved position, is unmodified (data not shown). It is not

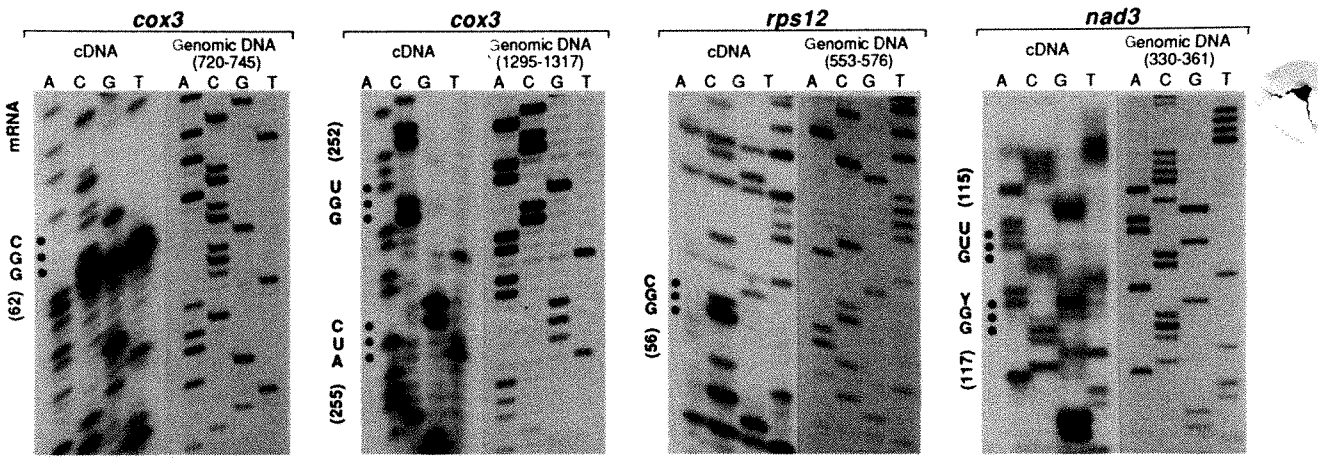

FIG. 1 Comparison of the cDNA and genomic DNA sequences in selected regions of *cox3*, *rps12* and *nad3*. For each gene, the right panel shows part of the cloned mt gene sequence (with the coordinates indicated in parentheses) and the left panel shows the corresponding cDNA sequence. The dots indicate the nucleotides of the mRNA codons deduced from the cDNA sequence, with codon positions given in parentheses (referred to in Table 1 and Fig. 3). For cDNA sequence, 5'-end ^{32}P-labelled synthetic oligonucleotides were hybridized with 70 μg of total wheat mtRNA in 14 μl of 250 mM KCl, 10 mM Tris-HCl, pH 8.3. Sequencing by the dideoxy chain-termination method using AMV reverse transcriptase was performed at 50°C for 60 min in 10 μl of a solution containing 3 μl of the primer-template RNA mixture, 8 mM $MgCl_2$, 0.5 mM of each dNTP, 4 mM DTT, 50 μg/ml actinomycin D and 0.2 mM of either ddATP, ddCTP, ddGTP or ddTTP. Oligonucleotides used as primers are complementary to the published gene sequences between the following positions: For *cox3* 762-786 and 1,332-1,356 (J.M.G., C. Domon, J.-H.W. and J.-M.G., submitted); for *nad3* 397-421 (ref. 6); for *rps12* 599-623 (ref. 6). Sequence of uncloned genomic mt DNA was obtained by the triple primer method as described[15], except that *Taq* DNA polymerase (Biolabs) was used for DNA amplification and T7 DNA polymerase (Pharmacia) was used for sequencing according to the manufacturer's instructions.

possible, therefore, to predict whether a CGG in a wheat mitochondrial gene will code for arginine or tryptophan, as this is dependent on whether RNA editing takes place. Our results show that as a result of RNA editing in wheat mitochondria, the universal genetic code can be used to specify tryptophan, without the requirement of divergence from the universal code postulated by Fox and Leaver[4].

By analysing cDNA sequences, we found differences between the deduced mRNA sequences and their corresponding gene sequences other than the ones involving CGG codons. We found 17 differences by comparing ~1,500 deduced mRNA nucleotides with the corresponding genomic sequences (Table 1). All these differences are C→U conversions, which occur at the first or second base of the codon and lead to a corresponding change of the amino acid encoded. But no modification was found in the 170 and 150 nucleotides sequenced in non-coding regions upstream of *cox3* and *cob*, respectively (data not shown), which indicates that the C→U editing acts to modulate the coding part of mRNA. In agreement with this, we found that the amino-acid sequences deduced from the edited mRNAs have more homology with those of the mitochondrial proteins of other species than do the amino-acid sequences deduced from the corresponding genes (Fig. 3). In some plants, the mitochondrial genome encodes amino acids in a particular protein that are the

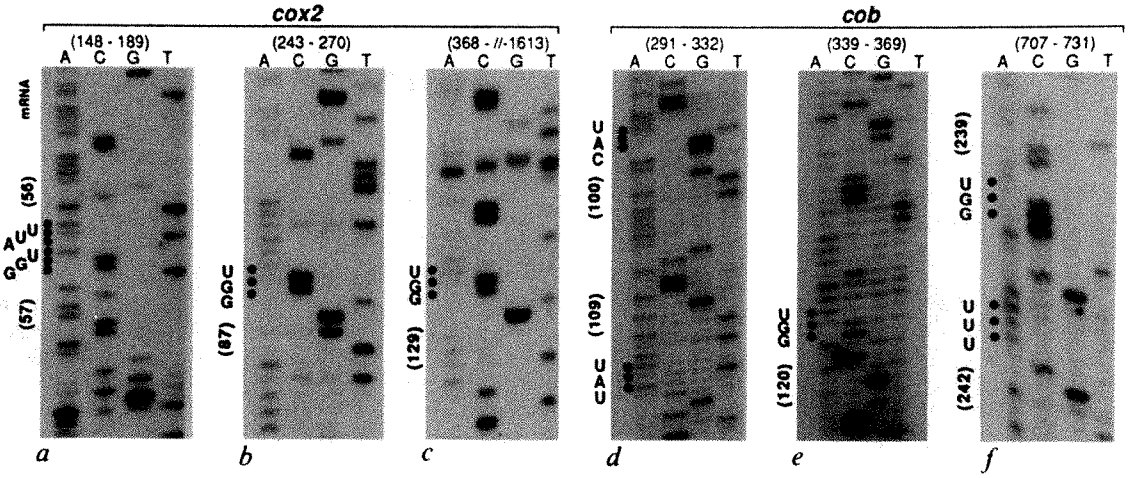

FIG. 2 Sequence of selected cDNA regions of *cox2* and *cob*. Sequences of the corresponding genomic DNA[8,9] are not shown, but their coordinates are given in parentheses. Codon positions are indicated as in Fig. 1. Sequence by the dideoxy chain-termination method using total mt RNA as template was as described in Fig. 1. Oligonucleotides used as primers are complementary to the published gene sequences between the following positions: For *cox2* (gels *a* and *b*), 292–316 (ref. 8); gel *c*, 1,638–1,662 (ref. 8); the latter primer allowed to sequence across the exons junction. For *cob* (gels *d* and *e*), 391–415 (ref. 9); gel *f*, 748–772 (ref. 9). For *cox1*, sequence not shown (1,474–1,498)[7].

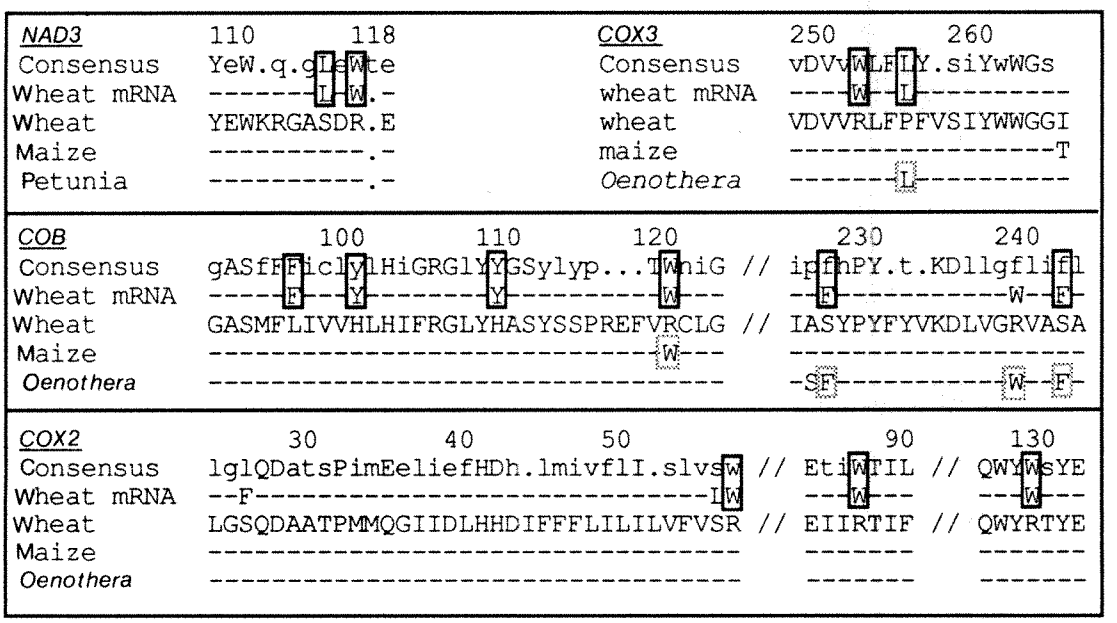

FIG. 3 Increases of mt protein sequence conservation due to C→U editing. Selected parts of the amino-acid sequence of several wheat mt proteins (deducted from the gene sequences using the universal genetic code) are compared with (1) the corresponding amino-acid sequence of mt proteins deduced from the gene sequences) from two other plants (one monocot and one dicot), (2) the amino-acid sequence deduced from the wheat mRNA sequence, (3) the consensus amino-acid sequence based on mt protein sequences from non-plant species (found in GenEMBL Data Bank). Dots in the consensus sequence indicate non-conserved positions, lower case letters indicate partial conservation, capitals indicate complete conservation. A dash indicates that the amino acid is identical to that deduced from the wheat genomic sequence. Solid line boxes indicate amino-acid homology with the consensus sequence, when editing of the wheat mRNA is considered. Dotted line boxes indicate amino-acid homology with mt proteins of other plants, when editing of the wheat mRNA is considered.

TABLE 1 Differences found in several wheat mt genes between the codons in the genomic sequences and the codons in the mRNAs (as deduced from the cDNA sequences)

Gene		mRNA	Localization of modified codons
CGG	—	UGG	*nad3* (117); *cox2* (57, 87, 129)
(R	→	W)	*cox3* (252); *cob* (120, 239)
CAC	—	UAC	*cob* (100)
CAT	—	UAU	*cob* (109)
(H	→	Y)	
TCA	—	UUA	*cox2* (56)
TCG	—	UUG	*rps12* (24); *nad3* (115)
(S	→	L)	
TCT	—	UUU	*cob* (227, 242); *cox2* (26)
(S	→	F)	
CTC	—	UUC	*cob* (96)
(L	→	F)	
CCG	—	CUG	*nad4* (316)
CCA	—	CUA	*cox3* (255)
(P	→	L)	

The positions where a C→U editing has been observed are underlined and the amino acids specified by the corresponding codons are indicated using the one-letter code.

same as the corresponding amino acids specified after editing in wheat mitochondria (Fig. 3). Furthermore, in these cases the non-edited genomic codons are the same as the corresponding edited nongenomic codons. This indicates that RNA editing has a role in the conservation of mitochondrial protein sequences during evolution.

The C→U conversion detected in wheat mitochondria has so far not been studied in other plants, but it is likely to occur, given the conservation of plant mitochondrial gene sequences[10]. In fact, the sequences of two cDNA clones of the *Oenothera cox3* gene show differences from the corresponding genomic sequences that can be explained by C→U conversions[11].

Plant mtDNAs can comprise several subgenomic molecules generated by homologous recombination[12]. It is possible that the U-containing RNAs were transcribed from T-containing DNA molecules not present in the genomic libraries used for the sequencing studies. For the edited *cox3 and nad4* transcripts, however, the sequencing of uncloned genomic DNA amplified by the polymerase chain reaction did not yield results in support of this idea (data not shown). Because hybridization of *cox3* and *nad4* probes with total wheat DNA only detected fragments corresponding to the mtDNA restriction map (not shown), the existence of T-containing DNAs in the nucleus could also be ruled out. Sub-stoichiometric DNA molecules in plant mitochondria[13] could comprise T-containing DNAs, but they would have to be selectively transcribed, which is unlikely.

If one excludes, therefore, the possibility that undetected genomic DNA templates code for wheat mtRNAs, the presence of non-genomically encoded U residues at specific positions in mRNAs can be explained either by a misincorporation of U residues by the mtRNA polymerase, or by a C→U conversion, which possibly involves a deamination step. This could be related to the C→U conversion that is required for the expression of the nuclear gene encoding apolipoprotein B (ref. 14). In any case, as RNA editing occurs in plant mitochondria, the sequence of mitochondrial proteins cannot be deduced solely from the gene sequence and should be checked by sequencing the corresponding cDNA. Because RNA editing is important in the modulation of gene expression, the mechanisms that it involves and the stage of mRNA synthesis or maturation at which it occurs need to be determined. □

RNA editing in plant mitochondria

Patrick S. Covello & Michael W. Gray*

Department of Biochemistry, Dalhousie University, Halifax, Nova Scotia B3H 4H7, Canada

A BASIC principle of molecular biology is that the primary sequence of RNA faithfully reflects the primary sequence of the DNA from which it is transcribed. This concept has been challenged recently by the discovery of RNA editing[1], broadly defined as any process that changes the nucleotide sequence of an RNA molecule from that of the DNA template encoding it. Examples of RNA editing (see ref. 2 for review) include the insertion and deletion of uridine residues in mitochondrial messenger RNAs in kinetoplastid protozoa[3], the conversion of a cytidine to uridine in mammalian apolipoprotein-B mRNA[4–7], and the appearance of two non-templated guanosine residues in a paramyxovirus transcript[8,9]. In these cases, RNA editing either re-tailors a non-functional transcript, producing a translatable mRNA[10,11], or modifies an already functional mRNA so that it generates a protein of altered amino-acid sequence[4–9]. Here we report an editing phenomenon that involves the conversion of cytidine to uridine at multiple positions in the mRNA for subunit II of cytochrome *c* oxidase in wheat mitochondria. Such RNA editing provides an explanation for apparent coding anomalies in plant mitochondria.

The alignment of the deduced amino-acid sequences of proteins encoded by mitochondrial (mt) DNA, such as that shown for cytochrome *c* oxidase (COXII) in Fig. 1, reveals several amino-acid positions that are invariant in non-plant species but seem to have undergone radical substitutions in one or more plant species. These substitutions include that of arginine for tryptophan at several positions (solid squares, Fig. 1), which originally prompted the suggestion that plant mitochondria use CGG to code for tryptophan rather than for arginine[12]. This is the only proposed deviation from the universal genetic code in plant mitochondria[13]. When, however, comparisons of other mitochondrial proteins are made, CGG codons in plant sequences align at positions specifying arginine residues in non-plant sequences[14,15], which implies that if CGG does code for tryptophan in plant mitochondria, it does not do so consistently. So far, no plant proteins encoded by mtDNA have been directly sequenced, so the issue of which amino acid is specified by CGG in plant mitochondria is unresolved. Furthermore, two separate transfer RNAs with different anticodons would be required if CGG as well as UGG were to specify tryptophan. As yet, only a single $tRNA^{Trp}$ that decodes UGG has been found in plant mitochondria[16,17].

It is also peculiar that although mitochondrial protein genes are highly conserved in the coding sequence among related plants, the few differences that are seen are expected to lead

*To whom correspondence should be addressed.

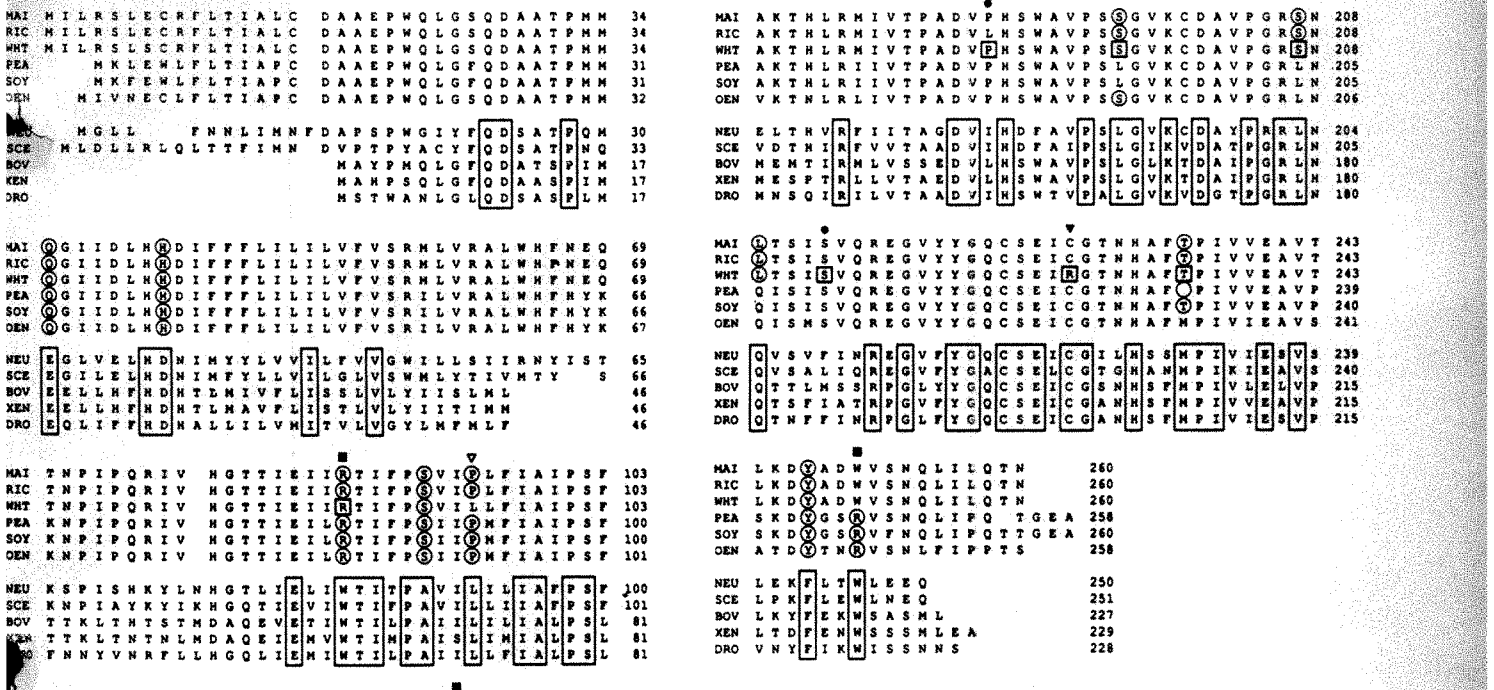

FIG. 1 Comparison of amino-acid sequences of COXII proteins from various organisms. DNA sequences for *Zea mays* (maize) (MAI), *Oryza sativa* (rice) (RIC), *Triticum aestivum* (wheat) (WHT), *Pisum sativum* (PEA), *Glycine max* (soybean) (SOY) and *Oenothera berteriana* (evening primrose) (OEN), obtained from NIH GenBank Version 57.0, were translated using the universal genetic code after revising the soybean sequence to agree with ref. 28 (C rather than G at position 680) and correcting the exon–intron junctions in monocots (wheat, maize, rice) (see Fig. 3). Sequences for *Neurospora crassa* (NEU), *Saccharomyces cerevisiae* (SCE), *Bos taurus* (BOV), *Xenopus laevis* (XEN) and *Drosophila melanogaster* (DRO) were obtained from the NBRF Protein Identification Resource. Amino-acid sequences were aligned using the algorithm of Feng and Doolittle[29]. Homologous amino acids completely conserved among the non-plant species are enclosed in solid lines. Substitutions at these positions in plants are circled. Residues altered by RNA editing in wheat are enclosed in a square. Symbols (closed circles and squares, open and closed triangles) indicate specific positions discussed in the text. Note that wheat position 228 corresponds to bovine position 200, not 196 as previously specified[18].

often to radical changes at the positions of otherwise highly conserved amino-acid residues. For example, the maize[12] and wheat[18] COXII-coding sequences differ at only nine positions in their 780-nucleotide coding region. Five of these substitutions are expected to result in three radical amino-acid changes in the wheat COXII sequence compared with that of the maize protein[18], which are (in the direction maize to wheat) Glu (GAA) to Ser (TCA) at position 7, Pro (CCA) to Leu (CTT) at position 95 (open triangle, Fig. 1) and Cys (TGT) to Arg (CGT) at position 228 (closed triangle, Fig. 1). The last difference is particularly puzzling because Cys 228 in maize COXII (and its equivalent in other COXII proteins) is thought to bind a catalytically essential copper atom.[19] Of all reported COXII sequences, only the wheat sequence apparently lacks cysteine at this particular position.

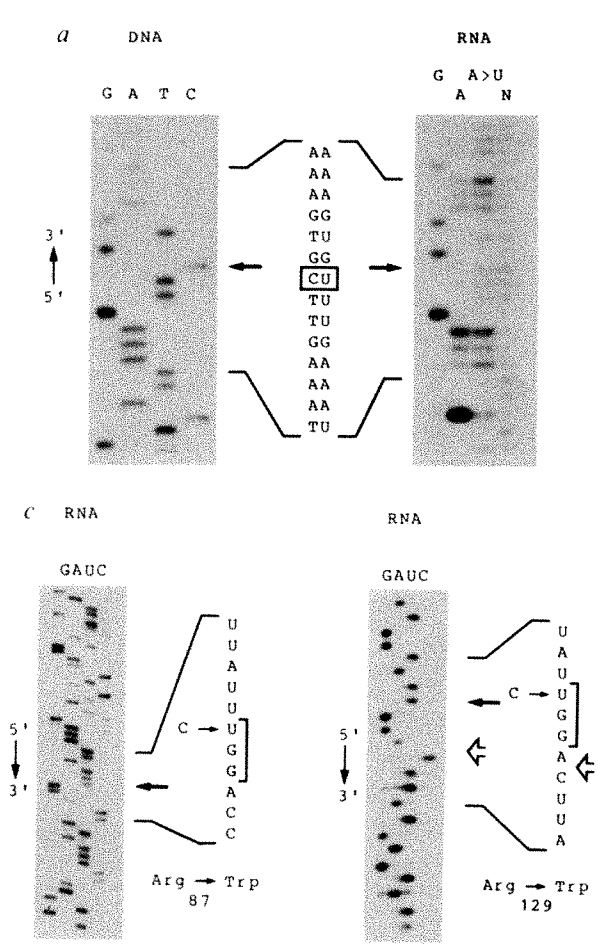
These irregularities led us to consider the possibility that in plant mitochondria, alterations in mRNA structure might act to maintain similarity at the protein level, despite sequence divergence at the gene level. A striking proportion (35 out of 56, or 63%) of the minimal changes that are required to convert anomalous codons in plant mitochondrial COXII mRNAs to codons that specify the consensus amino-acid residue in non-plant sequences are C → U conversions (Table 1). In fact, such C → U changes could resolve all of the coding anomalies in plant mitochondria mentioned above. In particular, selective conversion of CGG to UGG in mRNA would restore the expected (universal) codon at positions in plant mitochondrial proteins that in non-plants specify conserved tryptophan residues. Also, a C → U change in codon 228 (CGU, arginine) in the wheat COXII mRNA would switch this codon to UGU, permitting the incorporation of cysteine rather than arginine at position 228, so that the wheat COXII protein would now conform with all other COXII proteins at this site (solid triangle, Fig. 1).

The first indication that C → U RNA editing might actually occur in plant mitochondria came from the characterization of primary transcripts from wheat mitochondria (P.S.C. and M.W.G., manuscript in preparation). Direct sequence analysis of a 1.3-kilobase (kb) transcript, identified as COXII mRNA, showed that position −101 from the translation initiation site (within a 5′-untranslated leader of ~170-nucleotides) is occupied by U in the mRNA but by C in the previously determined sequence of the single-copy *coxII* gene[18] (Figs 2*a* and 3). We have observed the same difference between the gene and the mRNA sequence at the same position in a 0.8-kb transcript (corresponding to the mRNA of *orf25*, a gene of unknown function sequenced by L. Bonen; personal communication) that shares an identical 5′-terminal sequence of at least 85 nucleotides with COXII mRNA (data not shown).

We therefore examined the coding region in COXII mRNA by reverse transcriptase sequencing[20]. Figures 2*b*, *c* and Fig. 3

indicate the regions of RNA sequenced and draw attention to the nine differences found between the corresponding RNA and DNA sequences. These were all C in the DNA sense strand but U in the RNA. In the portions of COXII mRNA that were sequenced, the differences included all of the C→U changes indicated from amino-acid sequence comparison (Fig. 1 and Table 1), that is, codons 87 (Arg to Trp), 129 (Arg to Trp), 196 (Ser to Leu), 207 (Ser to Leu), 228 (Arg to Cys) and 235 (Thr to Met) (Fig. 3). In addition, codons 188 and 213 were both changed to specify Leu from specifying Pro and Ser, respectively (Fig. 3), consistent with the hydrophobic nature of the residues at the homologous positions in non-plant sequences (closed circles, Fig. 1).

Our observations provide evidence of a remarkable degree of C→U editing in wheat mitochondrial COXII mRNA. Such editing has the effect of altering the predicted COXII amino-acid sequence towards that of the non-plant consensus sequence at highly conserved positions, and explains the apparent coding anomalies in plant mitochondria. For instance, pending confirmation by direct COXII protein sequencing, wheat amino-acid residue 228 (corresponding to Cys 200 in bovine COXII[21]) can be reinstated as a universally conserved cysteine residue,



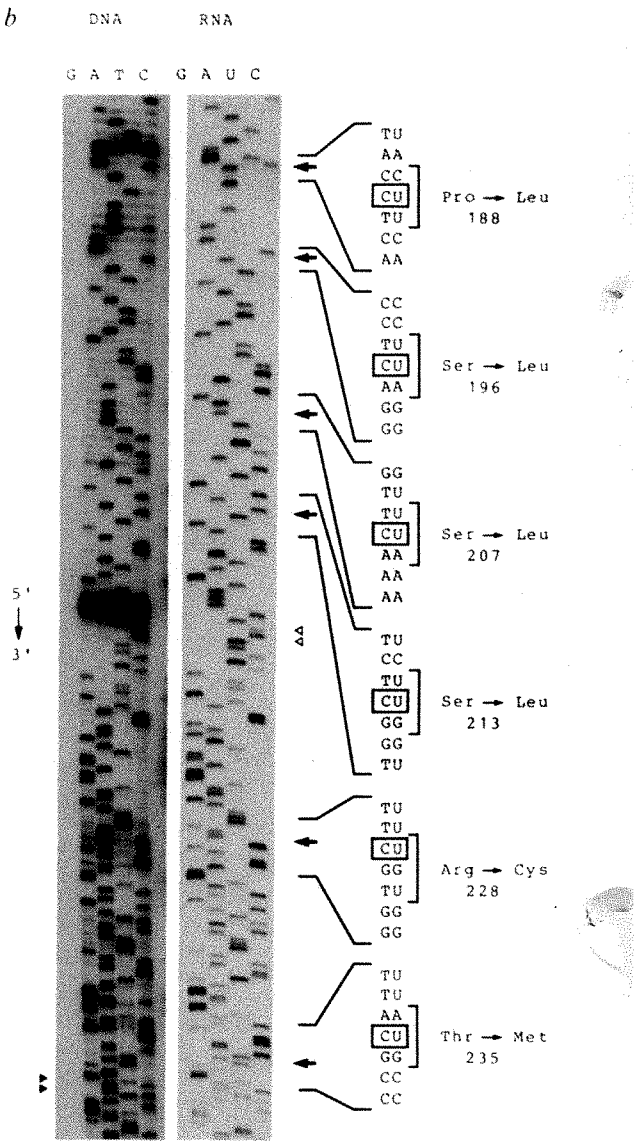


FIG. 2 Comparison of autoradiographs of DNA- and RNA-sequencing gels of the gene and mRNA for wheat mitochondrial COXII. *a*, 5′-Untranslated leader region showing C and U at homologous positions (arrows) in the DNA (RNA-like strand) and mRNA, respectively. The autoradiograph of the DNA sequencing gel was rotated 180° before being photographed to show an RNA-like sequence directly. *b*, Dideoxy sequence of DNA and RNA at the 3′ end of the COXII reading frame (exon 2), showing C→U editing of RNA (arrows). Autoradiographs have been positioned to display the complementary (RNA-like) sequence directly. Sequencing from DNA and mRNA templates was primed with the same oligodeoxyribonucleotide (primer 1, Fig. 3). Open triangles indicate ambiguous positions in the RNA sequencing gel, whereas the closed triangles show an area of compression in the DNA sequencing gel. The published DNA sequence[18] is shown for the latter region. *c*, Reverse transcriptase sequence of COXII mRNA across the exon 1–exon 2 boundary (open arrow) and through putative tryptophan codons (CGG) in exon 1 (solid arrows), using primer 2 (Fig. 3). Autoradiographs have been positioned to display the complementary (RNA-like) sequence.

METHODS. Primary transcripts (RNA species having pppN- or ppN-5′-termini) were capped[30] *in vitro* by incubation of NaCl-insoluble wheat embryo mitochondrial RNA[18,31] with [α-^{32}P]GTP and guanylyltransferase. A purified 1.3 kb band (isolated by PAGE) was sequenced by the enzymatic degradation procedure (see ref. 32) using RNases T1 (G), U2 (A), Phy M (A > U) and M1[33] (does not cut after C; data not shown). N, alkali. RNA sequence in the coding region was obtained by the dideoxy chain-termination method of reverse

transcriptase sequencing (ref. 17, procedure 2) using the primers 1 and 2 (sequence shown in lower-case letters in Fig. 3); these were extended in the direction indicated by the arrows in Fig. 3. To confirm the COXII gene sequence, M13 clones of wheat mtDNA, originally sequenced[18] using the Klenow fragment of *Escherichia coli* DNA polymerase I, were re-sequenced using the Sequenase system[34] (US Biochemicals). Note that in *a*, different varieties of wheat (Thatcher and Katepwa) were used for isolation of the COXII gene and of capped COXII mRNA, respectively. Therefore the difference between DNA and RNA observed in the 5′-untranslated region (position −101 in the COXII mRNA; Fig. 3) could be a manifestation of a strain-specific sequence difference at this position, rather than C→U RNA editing. For reverse transcriptase sequencing of the COXII mRNA coding region, however, three different mitochondrial RNA preparations (from Thatcher, Katepwa and Chinook wheat) were used as template with primer 1(*b*), whereas two preparations (Thatcher and Katepwa) were used with primer 2(*c*). Identical results were obtained with the different RNA preparations in each case.

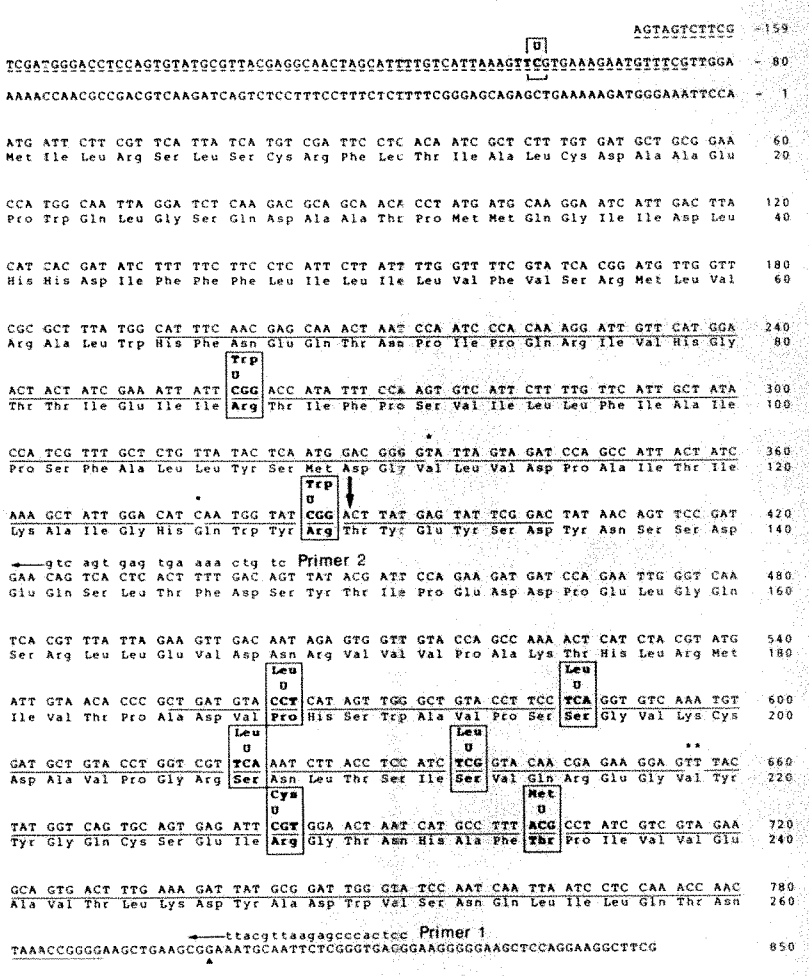

FIG. 3. Comparison of gene and partial mRNA sequence for wheat COXII. The complete DNA sequence (ref. 18, and unpublished observations) is shown and below it, the amino-acid sequence inferred using the universal genetic code. Unambiguous RNA sequence is underlined: broken underline, direct sequencing (beginning near the 5′ end of the capped transcript); solid underline, reverse transcriptase sequencing. Differences from the corresponding DNA sequence and in the amino-acid sequence deduced from the mRNA sequence are shown above the DNA sequence and are boxed. RNA sequence in the coding region was obtained by the dideoxy chain-termination method of reverse transcriptase sequencing[20] using the primers 1 and 2 (sequence in lower case letters; Regional DNA Synthesis Laboratory, University of Calgary). Asterisks indicate ambiguous nucleotide positions in the RNA sequence. The vertical arrow indicates the position of insertion of the single intron in the gene, precisely defined by the RNA sequence spanning the exon 1–exon 2 boundary (Fig. 2*c*). From this information, the DNA sequence at the exon–intron boundaries must be CGGAGTGCG...CAACCTTAT (intron sequence underlined); that is, the boundaries are two nucleotides upstream of those suggested previously for the maize[12], wheat[18] and rice[35] COXII genes. This shift changes the predicted amino-acid residue at position 130 of the COXII protein from Ser (AGT) to Thr (ACT) (Fig. 3). The downstream triangle indicates a residue previously reported to be A (ref. 18).

TABLE 1 Possible sites of RNA editing in plant COXII proteins

Position	Amino acid: Plant	Amino acid: Non-plant	Plant codon	Closest consensus codon(s)	Minimal change to yield consensus codon	Species: Monocots: Maize	Monocots: Rice	Monocots: Wheat	Dicots: Pea	Dicots: Soybean	Dicots: *Oenothera*

Inferred radical amino-acid substitutions in plant COXII sequences at positions that are invariant in five non-plant species are listed (see Fig. 1). Each amino-acid position is numbered according to the wheat sequence. The plant codons and the closest related codon corresponding to the amino-acid residue at the same position in the non-plant consensus are shown, along with the nucleoside change that would be required at the RNA level to convert the plant codon to the closest consensus codon. Amino-acid substitutions involving a chemical difference (based on polarity, molecular volume and composition[26]) >73 were considered to be nonconservative and were included in the table. +, Site at which a particular plant COXII protein differs from the non-plant consensus (that is, a possible site of RNA editing), with C→U changes indicated in bold. R denotes G or A.

* *Oenothera*, Y denotes U; other plants, Y denotes C.

† Dicots, N denotes G; maize, N denotes A; rice, N denotes U.

‡ Codon not present in the published pea COXII gene sequence[27].

supporting the view that it is involved in copper binding[19]. Our findings predict that examples of selective editing of mitochondrial mRNAs will be found in other plants. For example, conversion of codon 95 (CCA) in the maize COXII coding sequence[12] to either CUA or UUA would result in a proline-to-leucine switch at position 95 in maize COXII, restoring a conserved leucine that occurs at this site in the transmembrane domain of the COXII protein of wheat and other organisms (open triangle, Fig. 1). Finally, our data indicate that the universal genetic code is used in plant mitochondria, with non-edited CGG codons specifying arginine, not tryptophan.

RNA editing phenomena, such as we have described here, challenge the concept of faithful transmission of genetic information from DNA through RNA to protein. For plant mitochondria, it is clear that the gene sequence is an imperfect predictor of the protein sequence: mRNA or direct protein-sequence data, or both, are also required. This raises the important question of where the information introduced during the editing process originates, that is, how the selectivity of the process is achieved. No strong clues about this are provided by the examination of the primary sequence and the potential secondary structure in the vicinity of edited sites in wheat COXII mRNA. Furthermore, the timing of the observed RNA editing relative to that of transcription, its mechanism (for example, deamination versus base deletion–insertion), and its relationship to other forms of RNA editing, particularly the C→U editing of mammalian apolipoprotein-B transcripts[4–7], remain to be examined.

The discovery of yet another instance of RNA editing also raises the issue of just how general this phenomenon is. Protein sequence comparisons indicate that COXII mRNA editing is probably widely distributed among flowering plants (Table 1) and that editing extends to the mRNAs of other genes, such as *coxI* (data not shown). Given that plant mitochondria seem to be of direct eubacterial ancestry[22,23], it is pertinent to ask whether RNA editing may exist among the contemporary eubacterial relatives of plant mitochondria, the closest of which are found within the α-subdivision of the purple bacteria[24,25]. □

Kluyveromyces lactis toxin does not inhibit yeast adenylyl cyclase

John H. White, Andrew R. Butler & Michael J. R. Stark

Department of Biochemistry, The University, Dundee DD1 4HN, UK

KILLER strains of the yeast *Kluyveromyces lactis* secrete a complex protein toxin, production of which is associated with the presence of two linear double-stranded DNA plasmids, pGKL1 and pGKL2[1]. The toxin is encoded by two of the four genes carried by pGKL1[2] and is active against yeast from several genera (including *Saccharomyces cerevisiae*)[1,3]. The toxin arrests sensitive yeast cells in the unbudded (G_1) phase of the cell cycle[4], indicating that it could be used to study stage-specific events occurring in G_1. Previous work indicated that *K. lactis* toxin was a reversible inhibitor of adenylyl cyclase in sensitive *S. cerevisiae* cells[4]. Here we report that although the toxin does induce G_1 arrest, its effects on *S. cerevisiae* cells cannot be mediated by inhibition of adenylyl cyclase, and that treated cells never recover from its effects.

The addition of toxin to a culture of sensitive *S. cerevisiae* cells leads to a cessation of cell division within 1–2 generations, as indicated by the complete block in accumulation of cells after treatment with toxin (Fig. 1*a*). In treated cultures, we saw no further increase in cell numbers for over 35 h. Concomitant with this inhibition, we found that the proportion of budded cells in the population fell rapidly from ≥45% to ~10% (Fig. 1*c*). Because G_1 is the only phase of the cell cycle during which cells are unbudded, this clearly indicated that cells become arrested in G_1 after the addition of toxin. Treated cells, however, continue to increase in volume without substantial inhibition of protein and RNA synthesis (A.R.B., J.H.W. and M.J.R.S., manuscript in preparation), indicating that some degree of growth is possible in the arrested state. Previous work[4] indicated that the toxin had no effect on cell viability. But we found that the toxin caused a rapid and progressive loss of viability over the first 20 h, which was sufficient to explain the block to cell division (Fig. 1*b*). We used a range of toxin concentrations (Fig. 2) and were unable to find any conditions under which the arrest in cell division could be obtained without the loss of viability; concentrations of toxin too low to affect viability simply failed to arrest cell division. Although the treated population eventually seemed to regain viability (Fig. 1*b*), this was not due to the recovery of the inhibited cells, but rather resulted from the growth of spontaneously arising toxin-resistant cells, which are present in the starting population at a frequency of $\sim 2 \times 10^{-6}$. The regain of viability thus preceded the resumed increase in total cell numbers, and the change in cell numbers predicted from the viability data closely mirrors that observed experimentally (Fig. 1*a*). By the end of the experiment, all viable cells in the treated population are resistant to toxin (data not shown). In addition, treatment with toxin leads to a sixfold enrichment for respiratory deficient cells, although respiratory deficiency *per se* does not cause toxin resistance (data not shown). Moreover, the nonviable cells in the treated population were able to maintain a membrane potential, indicated by their failure to accumulate vital stains such as methylene blue or Janus green. This is in complete contrast to other yeast killer toxins, which act as ionophores[5]. Because the toxin is therefore an irreversible inhibitor, it is impossible to perform reciprocal shift experiments to map its execution point in the cell cycle. When cells are arrested in S phase with hydroxyurea, treated with toxin, and then the hydroxyurea block released in the continued presence of toxin, most of the budded cells are able to complete a round of division and become arrested in the unbudded state (data not shown). This indicates that the toxin-sensitive step occurs before the S phase. We therefore conclude that toxin leads to a permanent arrest of cells in G_1, such that they can never resume mitotic division.

FIG. 1 Effect of the *K. lactis* toxin on cell division, cell viability and budding index. Cells of LL20 (*MATα leu2-3, leu2-112, his3-11, his3-15*) were grown overnight in YPD (per l:10g yeast extract, 20g peptone, 20g dextrose) medium[10], subcultured at 10^6 cells per ml into fresh medium and shaken in flasks at 28 °C. When the cell density reached 3×10^6 per ml (time zero), the culture was split into two 20 ml portions using pre-warmed flasks, one of which received 5 mg l^{-1} purified *K. lactis* toxin[2] (~30 μM). This concentration of toxin was the minimum that gave complete inhibition of growth as measured using a microtitre well assay[11]. Samples from each culture were examined at regular intervals for total cell number per ml, number of viable cells per ml and the proportion of budded cells. Viable cells were determined by plating suitable dilutions of cells (in YPD) on YPD agar and incubating at 28 °C. □, Control; ■, plus toxin; ○, predicted curve for apparent recovery (see text).

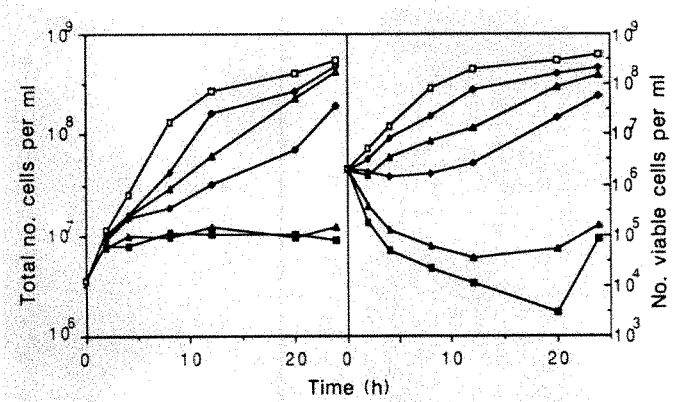

FIG. 2 Dose-response of sensitive cells to toxin. The experimental conditions were as described in Fig. 1 legend, except that several different toxin concentrations were used. □, No toxin; ◇, 250 ng l^{-1} toxin; △, 500 ng l^{-1} toxin; ◆, 750 ng l^{-1} toxin; ▲, 5 mg l^{-1} toxin; ■, 10 mg l^{-1} toxin.

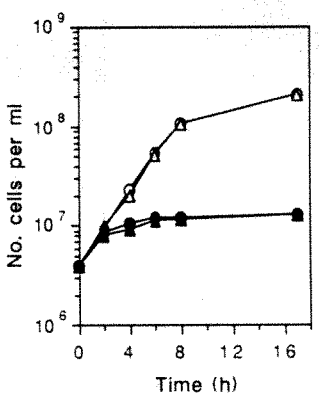

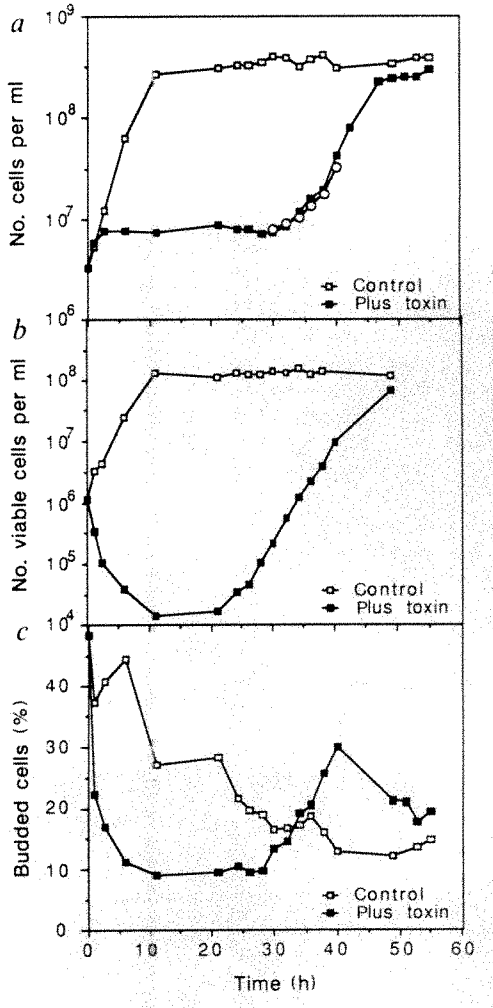

FIG. 3 Failure of cAMP and IBMX to antagonize toxin action. The experimental conditions were as described in Fig. 1 legend, except that strain JR242-17D (*MATα his3 ura3 trp*$^-$) was used and some cultures received cAMP and IBMX at time zero. ○, Control; ● and ▲, plus toxin (5 mg l^{-1}); △ and ▲, plus cAMP (5 mM) and IBMX (5 mM).

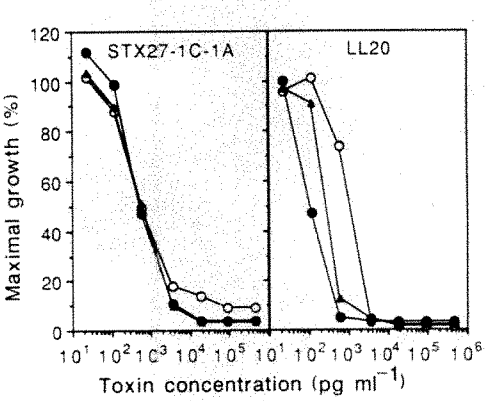

FIG. 4 Disruption of the *BCY1* gene does not render cells toxin-resistant. Growth of strains LL20 and STX27-1C-1A[4] was measured using a microtitre well assay[11] and growth of 10^5 cells in the presence of differing toxin concentrations expressed as a percentage of growth without toxin. The *bcy1*::*LEU2* disruptants derived from each strain were generated by standard methods using a previously described construct[8] and checked by Southern-blot analysis to confirm that the wild-type *BCY1* locus had been replaced. The *bcy1*::*LEU2* strains were further checked for heat-shock sensitivity, sensitivity to nitrogen starvation and failure to grow on acetate as a carbon source, all of which are characteristic of the *bcy1* mutant phenotype. ○, Parent *BCY1*$^+$ strains; ● and ▲, *bcy1*::*LEU2* disruptants derived from the parent strains.

We then re-examined the hypothesis that *K. lactis* toxin acts by inhibiting yeast adenylyl cyclase[4]. Previous work using strains STX27-1C-1A and F10D indicated that exogenous cyclic AMP antagonized inhibition by the toxin[4]. By using JR242-17D (Fig. 3), STX27-1C-1A or F10D, however, we have been unable to demonstrate any effect of added cAMP, alone or together with the phosphodiesterase inhibitor 3-isobutyl-1-methylxanthine (IBMX), on the efficacy of the toxin (Fig. 3, and data not shown). Moreover, we have used a genetic approach to demonstrate that the toxin does not act by preventing synthesis of cAMP. Because the only essential roles of cAMP in mitotic cell growth and division are mediated by cAMP-dependent protein phosphorylation, cells in which the catalytic subunits of the cAMP-dependent protein kinases are constitutively active no longer require cAMP to undergo growth and division[6,7]. This condition is readily produced by genetic disruption of the *BCY1* gene, the single locus that encodes the regulatory subunit of the cAMP-dependent protein kinases[7]. In fact, *bcy1* mutants[8] or strains with a disruption in the *BCY1* gene (J. Broach, personal communication) can grow in the absence of a functional gene encoding adenylyl cyclase. We have therefore generated derivatives from several yeast strains (including LL20 and STX27-1C-1A) in which the wild-type *BCY1* gene had been disruped by replacement with a *bcy1*::*LEU2* gene construct, and tested these for their response to toxin. In every case, these derivatives were fully sensitive to the toxin and showed growth arrest and loss of viability just as observed with the parent stains (Fig. 4, and data not shown). This indicates that toxin cannot exert its effects by inhibition of adenylyl cyclase. The mode of action of the toxin is therefore still unknown and it may yet prove a useful tool for examining stage-specific events in G_1. We anticipate that the toxin-resistant mutants that we and others[9] have isolated will provide the most direct route to characterizing the target of the toxin. □

Free-flow electrophoresis

H. Wagner

The continuous and simultaneous separation and fractionation of samples by free-flow electrophoresis has both analytical and preparative applications.

PIONEERING work by Hannig[1] led to the development of free-flow electrophoresis, also known as continuous-flow electrophoresis, as a technique for the purification of biopolymers, which now has broad applications in biology and medicine.

During free-flow electrophoresis, a thin film of electrolyte solution flows laminarly between two parallel cooling plates and an electric field is applied perpendicular to the flow, resulting in the differential deflection of charged solutes and particles. Depending on the mode of separation used, these substances are separated according to differences in either electrophoretic mobility or isoelectric point. The input of electrolyte solution and sample at one end of the electrophoresis chamber and fractionation at the other end are carried out continuously.

While free-flow electrophoresis can be used for analytical purposes, its continuous character lends itself to preparative applications. The need to solve purification problems in biotechnology has spurred interest in the preparative aspects of this technique[2].

Modes of separation

Free-flow electrophoresis has several separation modes[3] (Fig. 1), including zone electrophoresis[4], isotachophoresis[5], isoelectric focusing[6] and field-step electrophoresis[7].

Zone electrophoresis was the first free-flow electrophoresis separation mode to be developed. In this mode, a narrow sample stream is injected into a uniform background electrolyte, which usually has a constant pH and conductivity. Charged sample compounds are deflected by the electric field according to their electrophoretic mobilities. However, band broadening and dilution of the separated compounds can occur due to the laminar flow profile, diffusion and electro-osmosis. In spite of this, zone electrophoresis is still used for many applications, particularly in the separation of living cells.

The isotachophoresis mode is used for the separation of either positively or negatively charged particles. The sample is introduced into the separation chamber as a parallel zone between a leading and a terminating electrolyte. The mobilities of the sample compounds must be intermediate between that of the leading ion, which has the highest mobility, and the terminating ion, which has the lowest. The counter ions are chosen to have a high buffering capacity. If the steady state is achieved, all sample components move with equal velocity and are separated into individual zones. Ideally, there are as many zones as sample compounds. These adjoin without any spaces and in order of decreasing mobility. The concentration of the separated compounds depends only on the concentration of the leading ion and may be higher in the zone than in the original mixture.

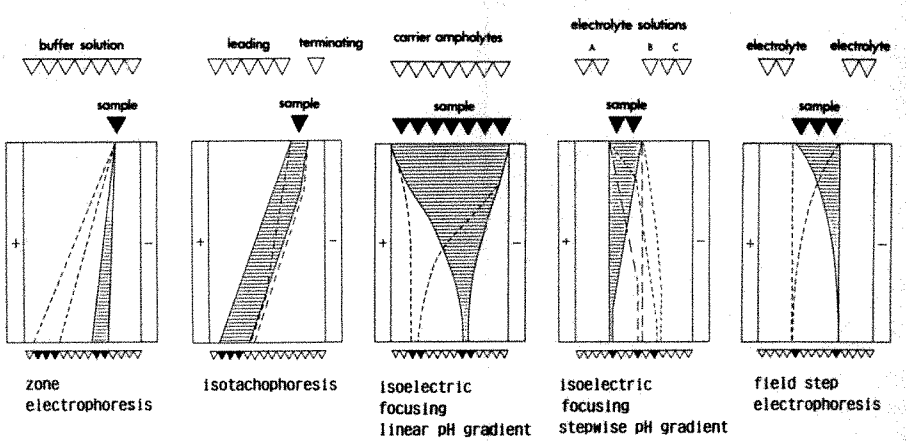

FIG. 1 Schematic representation of the different modes of separation with free-flow electrophoresis. ▽, background buffer; ▼, sample.

In isoelectric focusing mode, low molecular weight amphoteric substances — the carrier ampholytes — are introduced into the chamber, forming a linear pH gradient and causing proteins to be separated according to their isoelectric points. The pH gradient can be generated electrophoretically within the system by introducing a complex mixture of ampholytes. The sample can then be introduced either uniformly mixed with the ampholytes or as a narrow zone within the ampholyte mixture. A slow flow rate is necessary as the pH gradient must form and the sample compounds focus during the residence time.

As an alternative to forming the gradient electrophoretically, a stepwise, preformed pH gradient may be admitted. This avoids its time-consuming generation by the electric field. The stepwise pH gradient can be produced using a few solutions of pure amphoteric substances. The number of pH steps is given by the number of different solutions introduced. The sample is mixed and admitted with one of the solutions. This method allows the isolation of a single substance from a complex mixture.

In field-step electrophoresis mode, separation takes place in a discontinuous electrolyte system in which the sample solution with low ionic strength is flanked by two electrolyte solutions of high ionic strength. The conductivities of the two flanking electrolyte solutions must be about 20 times higher than that of the sample solution[7]. This results in a step-like profile for the field strength. Charged substances within the sample will migrate towards the respective electrodes according to electrical charge, but at the boundary with the solution of high conductivity, the migration velocity will be greatly reduced. Thus, focusing at the conductivity boundaries is due to the change in migration velocity, and not the loss of electrical charge, as with isoelectric focusing.

In spite of this, the direction of migration can be regulated by choosing a suitable pH when separating amphoteric substances such as proteins or peptides. However, as enrichment factors of only 10–15 are achieved during focusing, field-step electrophoresis is used mainly for the preseparation of complex mixtures.

Focusing using conductivity boundaries can be used in combination with isoelectric focusing. Although such methods need to be optimized for the specific separation problem, they result in high throughput and concentration of the sample.

Documented applications

The various applications of free-flow electrophoresis are documented in more than 500 publications, most of which are cited in review articles[3,4,8-10]. This technique has been used to separate substances of vary-

ing size, from small ions to whole living cells. With the latter, low electrostatic forces and the absence of carrier materials are a particular advantage. Successful separations on a laboratory scale of cells, subcellular particles, viruses and bacteria have been documented. Recently, free-flow electrophoresis has been used for the separation of peptides and proteins, including the separation and purification of single components from a complex biological mixture[2,11,12].

The pH, conductivity and composition of the electrolyte solutions can be freely selected within reasonable limits. The continuous nature of free-flow electrophoresis as opposed to most other physicochemical separation methods makes it suitable for not only analytical but also preparative separations, although scale-up is seriously hindered by the unavoidable generation of Joule heat. Despite this, advancements in the computerization of process control makes free-flow electrophoresis an attractive option for the pharmaceutical industry.

Instrumentation

In addition to the separation chamber, other components required for a complete free-flow electrophoresis instrument include an efficient cooling device with precise temperature control, a high-voltage power supply with a maximum capacity of 1,000 W, and high-precision pumps for the input of electrolyte and sample and for fractionation. An electronic unit controls the entire process and all peripheral equipment in conjunction with an online detection system for analysis of the separation profile during the run.

Various free-flow electrophoresis instruments have been developed but few are commercially available. One such instrument is the Elphor VaP 22 developed by Bender & Hobein, Munich, FRG, but instruments are also available from Hirschmann, Munich, FRG, and Protein Technologies, Tucson, Arizona. □

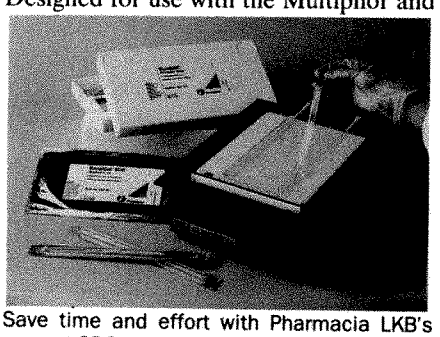
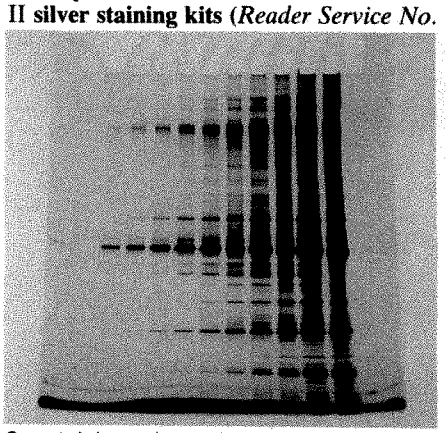
Molecules on the move



Microwave-in-the-bag agarose, a scanning densitometer with zig-zag optics, and an automated DNA sequencing system are among this week's products that focus on electrophoresis.

AMERSHAM Corp. is now offering **pre-labelled [^{35}S] DNA molecular weight markers** for use as standards in hybridization techniques, such as Southern blotting *(Reader Service No. 101)*. Each set of markers contains 17 fragments that range from 0.6 to 22.01 kb. The pre-labelled markers are supplied ready-to-use and, says Amersham, offer high resolution and an even distribution of fragments.

GELSIM is Biosoft's agarose gel **electrophoresis simulation and analysis package** which allows the user to enter banding patterns obtained from a set of running conditions and determine how the patterns change when the conditions are altered *(Reader Service No. 102)*. The adjustable running conditions include voltage, ionic strength of the running buffer, agarose gel concentration, duration of run, electrode separation and agarose gel length. The 'electronic' agarose gel provides eight lanes, each of which can hold up to 30 fragments. DNA fragments can be entered by size via the keyboard, or by position on the gel by moving the cursor. Features of the package include 30 pop-up help screens, banding pattern analysis, DNA size estimation, facility for printed gel summary sheets and hard-copies of the gel and banding patterns, and a diskette library of over 270 restriction digest fragment sets. The £99 (UK) GELSIM software is available on a 5.25-or 3.25-inch disc for use on an IBM PC.



Ready-to-use reagents

As an alternative to casting gels and mixing buffers, and for the rapid separation of SDS-denatured proteins in the molecular weight range of 6,500 to 300,000 daltons, Pharmacia LKB recommends its **precast SDS gradient gels and buffer strips** *(Reader Service No. 103)*. Designed for use with the Multiphor and Ultrophor IEF systems as well as other horizontal systems, the precast ExcelGel SDS, Gradient 8-18 gel media and precast ExcelGel SDS Buffer Strips eliminate the need for the preparation of toxic gel solutions, time-consuming gel casting and buffer preparation, says Pharmacia. Up to 52 samples or two 2-D maps can be run on each 110 × 245-mm gel, says the company. ExcelGel SDS, Gradient 8-18 gel media is supplied in packages of six plastic-backed gels and ExcelGel SDS Buffer Strips in packages of six anode and six cathode strips.

Save time and effort with Pharmacia LKB's precast SDS gradient gels and buffer strips.

According to Daiichi Pure Chemicals Co. Ltd, overstaining gels could be a thing of the past with their new 2-D Silver Stain II **silver staining kits** *(Reader Service No. 104)*. The kits can be used to stain plastic backed gels, IEF gels as well as regular gels, providing, says Daiichi, uniform staining of proteins with a high signal-to-noise ratio. The company says the procedure could not be easier: the 'stop' solution is added after 10 minutes of reduction and so there is no need to stand over the gel during the developing process. Each kit comes complete with six 100-ml plastic bottles containing sufficient reagents to stain 10 regular-sized gels or 20 minigels, says Daiichi.

Overstaining gels need not be a problem with Daiichi's silver staining kit.

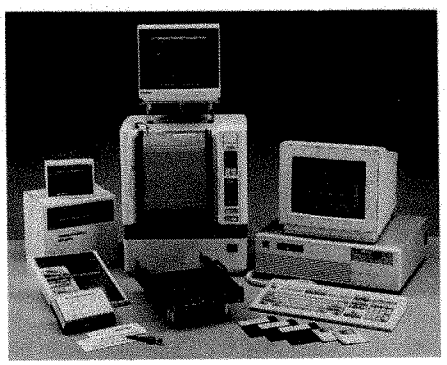
Cut down on reagent preparation with the convenience of **DNA agarose in microwavable pouches** from Integrated Separation Systems *(Reader Service No. 105)*. Preparation is simple — just snip the corner of the pouch and microwave for 1-2 minutes. Each pouch is sufficient for two 3-cm thick minigels, says ISS. The company offers a custom-blending service, where they will prepare gels with 0.5 to 1.5 per cent agarose with either Tris-

Borate-EDTA or Tris-Acetate-EDTA buffers. ISS says all reagents are tested for purity and reproducibility of results.

DNA fingerprinting

Non-radioactive DNA fingerprinting technology is now available in kit form with the SNAP DNA Fingerprinting Kit from Molecular Biosystems, Inc. (*Reader Service No. 106*). The SNAP kit has applications in tissue typing, identification and

The SNAP DNA fingerprinting kit from MBI.



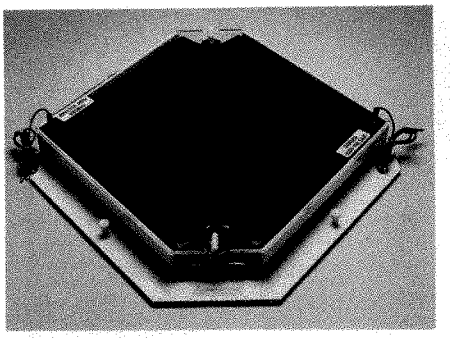
paternity studies, gene mapping and quality control of inbred or transgenic animals, says MBI. Hybridization to the complementary sequence in the target nucleic acid is achieved using synthetic oligonucleotide probes that are 20 to 30 bases long. Direct conjugation of alkaline phosphatase to the probe simplifies the protocol and reduces non-specific binding of the enzyme, which can produce increased background, says the company. Detection of hybridized target nucleic acid is by a one-step colour development process that results in localized blue staining. MBI says the assay takes less than four hours and each $195 (US) kit contains 50 pmols of probe — enough for about 300 hybridizations.

DNA fingerprinting probes for research use are now available from Cambridge Research Biochemicals (*Reader Service No. 107*). Developed in collaboration with Cellmark Diagnostics, the stated applications include verification of tissue culture cell-line purity, human chromosome mapping, plant and animal breeding and population genetics studies. The company is making available multi-locus DNA probes (33.15 and 33.6) and single-locus probes (MS1, MS31, MS43, MS8, and g3). The probes are full-length, purified DNA inserts, and are supplied as 60-ng aliquots suitable for direct labelling. Each vial comes with a Technical Data Sheet and sufficient material for the analysis of up to 50 genomic DNA samples on up to 10 membranes, says CRB.

Sequencing systems

For the quick and easy **preparation of nucleic acid sequencing gels**, National Diagnostics recommends its ready-to-use SEQUAGEL Sequencing System (*Reader Service No. 108*). Using Sequagel, which consists of acrylamide, bisacrylamide, urea and TBE buffer, gels from 0–20 per cent monomer can be prepared. The time-consuming and potentially hazardous process of weighing, mixing and filtering reagents is eliminated, says the company. The Sequagel solution is stabilized by the incorporation of a gaseous inhibitor, which, National Diagnostics says, prevents the 'self-polymerization' to which solid acrylamide is susceptible. The gaseous inhibitor is removed upon deaeration of the gel casting solution. Oxidation products such as aldehydes, which can alter migration, are removed by selective adsorption, producing consistent R_F values from run to run, says the company.

A re-engineered gel electrophoresis system and upgraded sequencing software are new features of the Acugen 402 **automated DNA sequencer** from EG & G Biomolecular (*Reader Service No. 109*). The Acugen 402 is, says the company, competitively priced at $35,000 (US), and uses standard radioisotopic labelling techniques (^{32}P) for the direct determination of DNA sequences at or above 99 per cent accuracy. The system's redesigned gel cassette improves the gel casting process and eliminates gel aberrations such as



Automated DNA sequencing with the upgraded Acugen 402 from EG & G Biomolecular.

lane drift, gel 'smiles' and 'frowns', says EG & G. The system can sequence 3,600 bases per day in two runs, says the company, and features the online viewing of raw data via a high-resolution monitor. The PC-compatible GENQUEST sequence analysis software has been upgraded to include more functions for base sequence determination and analysis.

Hardware options

Pulsed-field mapping and the separation of multi-megabase DNA fragments are possible with the OSP-20CP **constrained uniform field electrophoresis system** (CUFE) from Owl Scientific Plastics, Inc. (*Reader Service No. 110*). The CUFE system functions independently of voltage, gel thickness and buffer conductivity and can, says the company, be run at high voltages for rapid separations. No external circuitry is involved as 'baffles' physically constrain the electric field generated from platinum electrodes. The $3,695 (US) OSP-20CP comes complete with

Owl Scientific Plastics' constrained uniform field electrophoresis system.

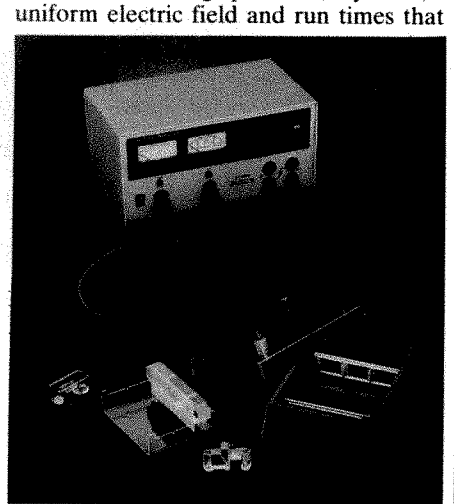
Reader Service No.15

programmable power inverter, recirculation system, gel casting tray that can accommodate 20 × 20-cm gels, comb and protocol.

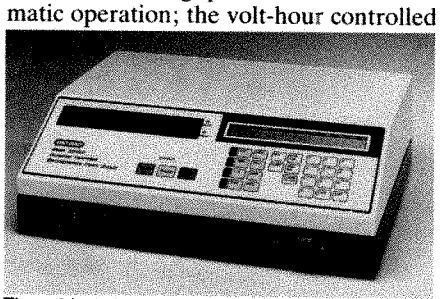


The safe internal recirculation of buffer and a built-in cooling system are features of the HE 100 SuperSub — Hoefer Scientific Instruments' **horizontal electrophoresis unit** *(Reader Service No. 111)*.

Hoefer Scientific Instruments' HE 100 SuperSub with buffer recirculation and built-in cooling system.

Buffer is continuously recirculated through a spiral coil built into the gel platform. When placed on a magnetic stirrer, a magnetic spinbar in the recirculation coil causes the buffer to flow over the top of the gel, which, says Hoefer, avoids ion depletion, pH changes and provides a uniform temperature. The design also features a serpentine heat exchange coil through which coolant can be pumped, simultaneously cooling the underside of the gel and the buffer flowing over the gel, says the company. The HE 100 can be fitted with a wide range of running plates for gels that are 20-cm wide and 15-, 20-, and 25-cm long.

The Little Blue Tank from Isco, Inc. is a multifunctional electrophoresis system that **combines minigel and electroelution techniques** into one system *(Reader Service No. 112)*. The $295 (US) system, not including the power supply, comprises a horizontal buffer tank, a 9 × 10-cm UV-transparent gel tray, combs for 12-lane analytical and 3-lane preparative gels, and two types of electroelution accessories. The electrode design provides, says Isco, a uniform electric field and run times that

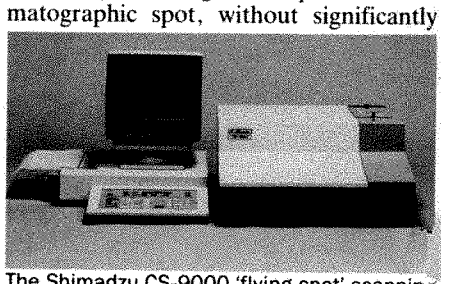


Isco's Little Blue Tank combines minigel and electroelution techniques into one system.

take 30–60 minutes at 50 V. Replacing the gel tray with up to four membrane-trap electroelution cups and varying the molecular weight cut-off point of the membrane between 1,000 and 50,000, provides a means of eluting proteins and other macromolecules from gels and solutions. Elution times for proteins are typically 1–4 hours with 80–100 per cent recovery, says Isco. Nanogram amounts of DNA can be recovered from gel bands by using the Nanotrap electroelution cups, says the company. The Little Blue Tank can also be used for concentrating biomacromolecules from solutions.

Power supplies

The Model 3000xi is the new programmable, high-voltage **electrophoresis power supply** from Bio-Rad Laboratories *(Reader Service No. 113)*. The unit can provide constant voltage to 3,000 V, current to 300 mA and power to 400 W. The 3000xi's 400-W capacity allows the unit to deliver 3,000 V and 150 mA simultaneously, says Bio-Rad. The unit has four operating modes: the three-level step function for programming up to three sets of running conditions; the time-controlled mode for setting parameters for automatic operation; the volt-hour controlled



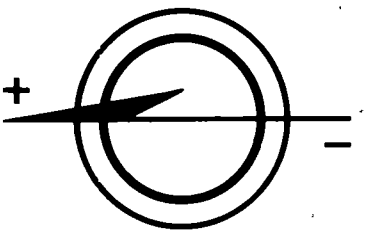
The Model 3000xi programmable high-voltage power supply from Bio-Rad.

mode which terminates a run after a preset number of volt-hours; and the memory operation mode for storing up to 10 sets of running conditions. At the touch of a button, the power conditions can be recalled from memory, ensuring, says Bio-Rad, reproducible operation in their electrophoresis cells and the precise control of runs.

For separating kilobase and megabase DNA in pulsed-field or field-inversion chambers, the E-C Apparatus Corp. recommends its EC720 **alternating controlled electrophoresis unit** *(Reader Service No. 114)*. The EC720 microprocessor-controlled unit can connect to any standard electrophoresis power supply and can run up to four chambers simultaneously. The unit supplies a voltage up to 1,500 V and current up to 500 mA. Ramped, stepped or compound changes can be programmed into the run. In addition, the unit will automatically compute the average forward voltage, watts and milliamps. The EC720 features an LED display of throughput voltage, and a 16-character four-line LCD display with a 20-pad input keyboard.

Detection and analysis

According to V.A. Howe & Co. Ltd, the latest optics and computer technology have been combined to produce the Shimadzu CS-9000 dual wavelength **scanning densitometer** for gels, TLC plates and autoradiograms *(Reader Service No. 115)*. The £15,490 (UK) CS-9000 features 'zig-zag' scanning optics, which, the company says, eliminates errors caused by the irregular shape of a chromatographic spot, without significantly



The Shimadzu CS-9000 'flying spot' scanning densitometer from V.A. Howe.

affecting scan speed. The instrument can function in transmission, reflection and fluorescence modes, and has a measuring wavelength range of 200–650 nm and a resolution of up to 50 microns, says Howe. Other features include a trace scan function for automatically tracking non-linear separations, background correction function, and colour video display with menu-driven multipage system. Instrument parameters, automatic programs and calibration curves can be stored in the 16-Kbyte memory and hard copies can be printed via the parallel head printer.

Southern-Light Plus from Tropix is the new **chemiluminescent detection and labelling system** for analysing membrane-bound DNA from Southern blots and other DNA hybridizations *(Reader Service No. 116)*. The test kit features the chemiluminescent one-step substrate AMPPD, which is directly activated by alkaline phosphatase, and which can detect as low as 10^{-20} moles of enzyme, says Tropix. The Southern-Light visualization reagents can also be used with biotinylated and digoxigenin-labelled probes. Results are imaged on X ray or instant film within a 5–60 minute incubation period at room temperature, says the company. Each kit consists of Southern-Light visualization reagents and the Trans-Light system for biotinylating DNA using nick translation, and contains sufficient reagents for 50 10 × 10-cm nylon blots. □

Nestlé

Our Research Centre situated north of Lausanne (Switzerland) is looking for a

FOOD ENZYMOLOGIST

who will be in charge of studying enzymatic changes in raw materials during growth, processing and conservation in order to maintain their taste, texture, colour, and avoid development of "off flavours".

If you are Biochemist or have a similar education with a PhD in enzymology, preferably food enzymology, or equivalent experience.

Please send your application with curriculum vitae to

Mrs M. Germanier
Audrin,
Nestlé Research Centre,
Personnel Office, P.O. Box 353,
CH – 1800 Vevey (W6614)A

UNIVERSITY OF KENT AT CANTERBURY

Research Fellow in Yeast Molecular Biology

Applications are invited for the post of Postdoctoral Research Fellow in the laboratory of Dr M F Tuite. The successful applicant will carry out a molecular genetic analysis of a novel translation factor from *Saccharomyces cerevisiae* applying both classical and site-directed mutagenic techniques.

Applicants should either have a PhD or be in the process of submitting for their PhD in the area of molecular biology, biochemistry or genetics. Appointment will be made on the RA1A scale (£10,458 to £16,665) and will be for three years. The start date is negotiable but should ideally be on or before January 1st, 1990.

Application forms are available from **Mr J E Reilly, Secretary of Faculties and Deputy Registrar, The Registry, University of Kent at Canterbury, Kent, CT2 7NZ** quoting reference A90/8. Informal enquiries about the post can be made to Dr Tuite by telephone on (0227) 764000 extn 3699. The closing date for applications is 1st November 1989.

The University is an Equal Opportunities Employer.
(1884)A

ASSISTANT/ASSOCIATE PROFESSOR
BANTING AND BEST DEPARTMENT OF MEDICAL RESEARCH
UNIVERSITY OF TORONTO

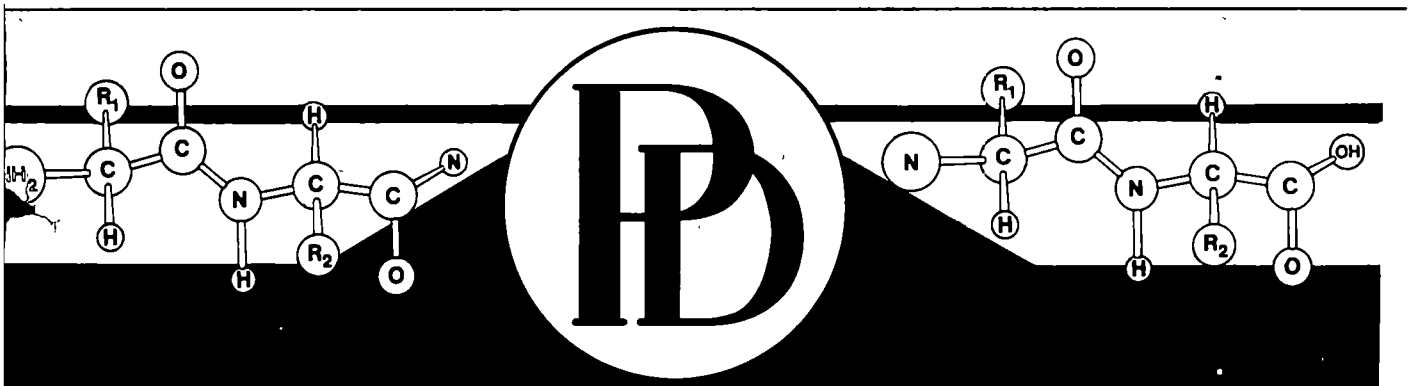
The Banting and Best Department of Medical Research, i seeking candidates for the position of Assistant/Associat Professor (Tenure stream). The position is available July 1 1990 and will carry an initial appointment of five years at competitive salary.

Candidates should have a strong research background an be prepared to develop a research program in an area relate to the Molecular Basis for Cellular Regulation, includin Molecular and Cellular Aspects of Endocrinology, Mec anisms of Signal Transduction, Surface and Intracellula Receptors, Control of Growth and Differentiation, Diabete Research, or Regulation of Gene Expression. The successfu candidate will be expected to attract independent researc grants, to spend at least 7.5% of his/her time in research an to participate in graduate and undergraduate training. *Th University of Toronto encourages both women and men t apply for positions.*

Applicants should forward a Curriculum Vitae, an outline o research interests and arrange for three letters of reference t be sent directly to **Dr. David H. Maclennan, Professor an Chairman, Banting and Best Department of Medical Research University of Toronto, 112 College Street, Toronto, Ontario Canada M5G 1L6.**

In accordance with Canadian immigration requirements priority will be given to Canadian citizens and permanen residents to Canada, but foreign applications are encouraged.
(NW4382)A

UNIVERSITY OF NEWCASTLE UPON TYNE



CHAIR OF PHYSICS

Applications are invited for the established Chair of Physics in the Department of Physics.

Preference will be given to experimentalists with a vigorous research programme in applied solid state physics and optical spectroscopy complementary to existing theoretical areas in the Department. The successful candidate will be expected to build up a strong research group which would provide a basis for further advancement of departmental and regional effort in this subject. The University intends to appoint a lecturer in support of this research area in October, 1991.

Salary will be at an appropriate point on the professorial scale.

Further particulars may be obtained from the **Registrar, University of Newcastle upon Tyne 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU,** from whom applications (15 copies) giving the names of three referees, should be lodged not later than 8th December 1989. (Applicants outside the UK may submit one copy only). (1876)A

Parke Davis Research Unit, Cambridge.

DIRECTOR: DR JOHN HUGHES

RESEARCH ASSOCIATES IN BEHAVIOURAL PHARMACOLOGY

This unique Unit is developing new generation drugs for the treatment of nervous and neurohormonal disorders. Our basic research interests centre on the function and mechanism of actions of hormones and neurotransmitters at the behavioural, cellular and molecular levels with particular reference to peptides. We have a number of strong research programmes involving permanent staff, Ph.D. students and Post-Doctoral Fellows. Collaborative projects with various University, Research Council and Hospital research groups are also in progress.

The opportunity has arisen for several young, highly motivated pharmacologists to join a team studying the behavioural effects of neuropeptides. Applicants for these tenured positions should hold, or be expecting to obtain, a good first degree in Pharmacology or related subject, or have recently obtained a Ph.D. in Behavioural Pharmacology. Full training can be provided for suitable candidates who may not have extensive experience in behavioural pharmacology but who wish to develop their expertise in this area. The successful candidates will be encouraged to contribute to the active publication programme of the research group and to participate at scientific meetings. These positions, which are available immediately, carry a salary on a scale rising to £21,061 per annum. Starting salary will be dependent upon qualifications and experience. Other benefits include relocation assistance where appropriate.

Applications should be accompanied by a full up-to-date curriculum vitae describing research experience, together with the names of two scientific referees and be sent to Dr. Chris Bruton, Parke-Davis Research Unit, Addenbrooke's Hospital Site, Hills Road, Cambridge, CB2 2QB, to arrive as soon as possible and in any event by 3rd November 1989.

WARNER LAMBERT

(1895)A

The University of Virginia
Beirne Carter Center for Immunology Research
Endowed Chair in Immunology

The University of Virginia is seeking an outstanding scientist to provide intellectual leadership for the Beirne Carter Center for Immunology Research. The Center is an interdepartmental program with the overall goal of fostering and coordinating research and research training in immunology. The Center is newly formed as the result of a gift from a University alumnus. Research will focus on the fundamental mechanisms underlying the induction and regulation of immune responses.

Funds are available to recruit scientists to fill several faculty positions. Candidates of those wishing to nominate outstanding individuals should direct their communications to:

Rodney L. Biltonen
Pharmacology Department
Box 448, Health Sciences Center
University of Virginia
School of Medicine
Charlottesville, VA 22908

The University of Virginia is an Equal Opportunity/Affirmative Action Employer

(NW4328)A

THE OHIO STATE UNIVERSITY

CHAIR
DEPARTMENT OF CHEMISTRY

The Ohio State University invites nominations and applications for the position of Chair of the Department or Chemistry. The applicant must demonstrate suitable administrative and academic leadership skills for this position, which will be open in July 1990. The Ohio State University is a major comprehensive University. The Department of Chemistry, with 41 faculty, has 240 graduate and 35 postdoctoral students, and has extensive research programs in most areas of chemical research.

Applicants, who must have established strong research credentials in some branch of Chemistry, should write to **Dr. Leo Paquette, Chairman, Search Committee, Department of Chemistry, The Ohio State University, Columbus, Ohio 43210-1173** (614-292-2520) giving the names of three or more referees. Applications/nominations received by December 31, 1989 will receive full consideration.

The Ohio State University is an affirmative action/equal opportunity employer. (NW4398)A

UNIVERSITY OF OXFORD

Professorship of Applied Statistics

The electors intend to proceed to an election to the Professorship of Applied Statistics, which falls vacant on 1 October 1990 by the retirement of Professor P. Armitage. The stipend of the professorship is at present £28,521.

Applications (ten copies, or one from overseas candidates), naming three referees, should be received not later than 11 December 1989 by the **Registrar, University Offices, Wellington Square, Oxford OX1 2JD,** from whom further particulars may be obtained. (1875)A

The University is an Equal Opportunity Employer

NEUROSCIENCES GROUP, INSTITUTE OF MOLECULAR MEDICINE and DEPARTMENT OF ZOOLOGY, UNIVERSITY OF OXFORD
ELECTRON MICROSCOPIST

A post doctoral research assistant is required for a three year project grant, starting 1st October, 1989, funded by the Wellcome Trust to investigate abnormalities of the neuronal cytoskeleton in toxic and diabetic neuropathies using freeze-fracture deep-etch electron microscopy. Experience in electron microscopy essential, additional experience in freeze-fracture techniques, immunolabelling or neuroanatomy would be an advantage.

Salary on the RS1A scale £10,458-£11,736

Applications, with the names of three referees to:

Dr Michael Donaghy, University Department of Clinical Neurology, Radcliffe Infirmary, Oxford OX2 6HE

Further information from Dr M Donaghy (0865 249891 X4698) or Dr D Shotton, Department of Zoology (0865 271193).

THE UNIVERSITY IS AN EQUAL OPPORTUNITY EMPLOYER (1867)A

UNIVERSITY OF ABERDEEN
DEPARTMENT OF BIOCHEMISTRY
RESEARCH FELLOW/ASSISTANT

Required to work on a project funded by the EEC "Development of a vaccine for the salmon louse". Experience in recombinant DNA technology would be an advantage. The post is funded for 18 months and the salary will be within the range £9,816-£16,665 with placement according to qualifications and experience.

For further information on the project please contact Dr Melvin on (0224) 273110. Applications by letter with CV including the names of three referees to the **Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX** by 10 November 1989 quoting reference number LW/059. (1869)A

UNIVERSITY COLLEGE LONDON
Department of Anatomy and Developmental Biology
EDITORIAL RESEARCH ASSISTANT

required from 1 December 1989, to work with the Head of Department, Professor G Burnstock. Experience is required in biomedical research together with the ability to edit scientific material. The editorial assistant is an integral part of a team of research workers which includes many overseas visitors. Familiarity with computer-based word processing would be an advantage.

Salary range (IA) £10,458 - £16,665 + £1,650 London Allowance.

Appointment for 1 year in the first instance. Applications, together with full CV and names and address of two referees to: **Professor G Burnstock, Department of Anatomy & Developmental Biology, University College London, Gower Street, London WC1E 6BT.**

Closing date for applications: October 27th 1989. (1874)A

UNIVERSITY OF KENT
AT CANTERBURY

Biological Laboratory

Research Fellow
In Protein Engineering/Molecular Graphics

A post-doctoral researcher is sought for a two-year post funded by SERC and the University to establish a molecular graphics facility for a macromolecular modelling based on a newly-installed Silicon Graphics 4D/20G personal IRIS workstation, and to contribute to ongoing protein engineering research programmes. The post, with Professor Robert B Freedman, is available immediately and will be appointed on the RA1A scale (£10,458-£16,665). (Reference Number A90/7).

Research Technician

In Molecular/Cell Biology of Neurofilaments

A Research Technician post funded by SERC is available immediately with Dr Martin J Carden to investigate the cell and molecular biology of neurofilaments, protein filaments that are major components of the neuronal cytoskeleton. Candidates with experience in any of the following will be preferred: hybridoma culture, immunochemistry, protein purification/SDS-PAGE, DNA cloning. The post is for two years and will be appointed on the Technician Grade F Scale (£12,325-£13,872). An appointment will not be made above £13,468 on the scale. (Reference Number T90/7).

Application forms for either of the above posts are available from **Mr J E Reilly, The Registry, University of Kent, Canterbury, Kent, CT2 7NZ (Tel: 0227 764000 ext 3915).** Further details of each post can be obtained quoting the appropriate reference number from Professor Freedman (x 3443) or Dr Carden (x 3993), as appropriate.

The closing date for applications is 1st November 1989.

The University is an Equal Opportunities Employer. (1885)A

INTERNATIONAL WEEKLY JOURNAL OF SCIENCE seeks a NEWS REPORTER

Essential qualifications:
* A good science education
* Capacity to write fluently

Other relevant qualifications:
* Experience as a journalist
* A second European language
* First-hand knowledge of research

Salary by negotiation. London-based, but the successful applicant must be prepared to travel. Apply with full *curriculum vitae* and names of two referees to the **Editor, *Nature*, 4 Little Essex Street, London WC2R 3LF** as soon as possible. (1780)A

FACULTY POSITIONS IN PHYSIOLOGY – TULANE

Applications are invited for tenure-track appointments at all ranks. Candidates should hold the Ph.D. or M D. degree, have a record of excellence in research, and be committed to teaching of medical and graduate students. Research areas marked for expansion include, but are not limited to, cardiovascular-renal, cellular/molecular, and membrane transport physiology. Previous applicants need only send updated material and a letter indicating continued interest. Send a resume, description of research program, reprints, and four letters of recommendation to: **Dr. L. Gabriel Navar, Chairman, Department of Physiology, Tulane University School of Medicine, 1430 Tulane Avenue, New Orleans, LA 70112.** *Tulane University is an Affirmative Action/Equal Opportunity Employer.* (NW4399)A

RESEARCH SCIENTISTS – SENIOR RESEARCH SCIENTISTS

A$31,525-A$45,699

DIVISION OF ENTOMOLOGY CANBERRA ACT AUSTRALIA

THE DIVISION: The Division of Entomology is the major entomological research organisation in Australia and conducts basic and applied research on the taxonomy, ecology, physiology, behaviour, pathology, genetics and molecular biology of insects and related arthropods. Major activities inlcude. the development of methods of control of arthropod pests by biological, physical and chemical means in order to develop integrated pest management strategies in crop and livestock systems and for grain storage; the control of weeds by biological agents, and studies of the molecular biology of insect species that combine the techniques of genetics and genetic engineering to develop novel methods of pest control.

The Division has a professional staff of 120 located at nine Australian CSIRO sites and five overseas stations. The Division's headquarters and main laboratory complex are in Canberra. The Division has good technical support services including photographic and illustrating facilities, scanning and transmission electron microscopes, on-line access to several mainframe computers with associated software, and excellent library facilities.

MOLECULAR BIOLOGISTS

THE PROGRAM: The Division's Molecular Biology and Physiology Section undertakes strategic research into the molecular biology of insect development, reproduction and pathology; into the development and exploration of gene transfer technology for insects and their bacteria and viruses; and into the construction of safe but effective biological insecticides. This research program is strongly supported with industry funds. Some current projects concern the hormonal control of reproduction in *Drosophila* and the Australian sheep blowfly, *Lucilia cuprina*, insecticide resistance in *Lucilia*, phase changes in entomopathogenic bacteria, gene transfer procedures for *Drosophila* and *Lucilia* and the molecular analyses of various insect viruses

REF NO. P0373

THE JOB: The appointee will undertake research into the biochemistry and molecular biology underlying the insecticidal activities of certain insect viruses

THE PERSON: Applicants should hold a PhD degree or equivalent qualification in a relevant field and have appropriate research experience in protein biochemistry and molecular biology Experience in virology would be highly desirable

REF NO. P0374

THE JOB: The appointee will undertake research to develop technologies for the genetic manipulation of certain insect viruses. The appointee will also interact closely with staff involved in related projects within the Division.

THE PERSON: Applicants should hold a PhD degree or equivalent qualification in a relevant field as well as appropriate research experience in virology and molecular biology

INSECT PATHOLOGIST

REF NO. D0375

THE PROGRAM: The Division's Pathology and Behaviour Section undertaken strategic and tactical research into the development of non-insecticidal means of pest control. Current research is concerned mainly with insect pathogenic nematodes, entomogenous fungi and the use of sex pheromones of Lepidoptera for control by mating disruption Facilities include transmission and scanning electron microscopes as well as the mass spectrometry unit.

THE JOB: The successful applicant will form part of a team working on the development of the green muscardine fungus, *Metarhizium*, as a mycoinsecticide for soil insects and particularly termites. The research will be concerned with developing new strains of the fungus with improved characteristics, as well as improving our understanding of the physiological and genetical processes involved in pathogenicity and conidial survival In addition the factors which affect the field efficacy of the applied fungus will be an important component of the research Commercial links are being negotiated at present

THE PERSON: Applicants should possess a PhD or equivalent in relevant field with experience in mycology especially genetics and biochemistry. Experience in developing microbial pesticides would be an advantage

FURTHER INFORMATION: Prospective applicants for Molecular Biologist positions are invited to telephone for Dr John Oakeshott 61 62 46 5790 for more information Prospective applicants for the Insect Pathologist position are invited to telephone Dr Richard Milner on 61 62 46 5344 Copies of the selection criteria can be obtained from Ms Jody Scrivener 61 62 46 5075

APPLICATIONS: Applications for these positions should be submitted by 10 November, 1989 and should quote the appropriate reference number Applications should be framed against the selection criteria, stating relevant personal particulars including details of qualifications and experience Applicants should nominate at least two professional referees and address their applications to:

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

AB1-89/23

NEW SENIOR POSTS IN RESEARCH ADMINISTRATION

Following some internal promotions and the setting up of some new scientific initiatives, the Medical Research Council wishes to appoint a small number of scientists to join its team of Scientific Administrative Officers at the MRC Head Office in London.

Scientific Administrative Officers act as one of the main channels of communication between those in universities, hospitals and research institutes whose research is supported by the MRC or who are seeking support, and the Council and its decision-making Boards and Committees. They also play a major role in the development of the Council's research policies for particular scientific fields. Each is assigned to take responsibility for a group of related scientific areas.

Minimum qualifications are a good honours degree in a relevant science subject together with at least four years relevant research experience. The successful candidates are likely to have had some proven post-doctoral research experience in an academic or other research environment. Candidates will need to demonstrate a broad working knowledge of science and medicine, and have the analytical, communication and representational skills necessary to handle, after training, the complex administrative aspects of research management.

This is an unusual and challenging opportunity to move from research into strategic research administration. Appointments will be to the Senior Scientific Officer grade, which has a current salary of £15,534 to £20,614 (including London Weighting) plus a 4.5 per cent supplement for those joining the MRC Pension Scheme. Additional performance payments are available for the best staff. Conditions include pleasant office surroundings near Regents Park and flexible working hours.

MRC
Medical Research Council

For application forms and further particulars apply by letter or telephone to **HQ Staffing Group, Medical Research Council, 20 Park Crescent, London W1N 4AL.** Telephone 01-636 5422 ext 447. Closing date: 10 November 1989.

An equal opportunities employer. (1890)A

TENURE-TRACK FACULTY POSITIONS: THE CENTER FOR NEURAL SCIENCE OF NEW YORK UNIVERSITY

invites applications for tenure track faculty positions in th general area of systems and in tegrative and neuroscience.

Candidates should be able t demonstrate excellence and ori ginality in experimental and/o theoretical research. Appoint ments may be made at any leve The Center for Neural Science i an interdepartmental unit of th Faculty of Arts and Science, co operating with the Department of Biology, Chemistry, Compute Science, Mathematics, Physic and Psychology New member of the Center hold appointment jointly in the Center and one o more of these Departments

Candidates should send a cur riculum vitae, a statement of cur rent research interest, copies c relevant publications and th names and addresses of three o more individuals willing t provide letters of reference, to.

LEICESTER BIOCENTRE
UNIVERSITY OF LEICESTER

YEAST MOLECULAR BIOLOGY

Two positions are available in the laboratory of Dr Peter A Meacock to work on the molecular biology of cytoplasmic linear DNA plasmids of the dairy yeast *Kluyveromyces lactis*, with particular emphasis on their replication. These posts are funded by a AFRC grant and are available from October 1st 1989 for up to three years

Position #1

Postdoctoral Research Associate 1A (Salary scale £10,458-£16,665)

Candidates should have, or be about to obtain, a PhD in a relevant subject.

Position #2

Graduate Research Assistant 1B (Salary scale £9,816-£12,381)

Candidates with suitable qualification (1st or IIi class degrees) may be eligible to enrol for a higher degree.

Applicants for both positions should have a strong background in biochemistry and experience of protein purification, enzymology and molecular biology techniques would be an advantage

Applications, including a full CV and the names and addresses of two academic referees, should be sent as soon as possible to– **Dr Peter A Meacock, Leicester Biocentre, University of Leicester, University Road, Leicester LE1 7RH,** who can also supply further information. **(Tel: 0533-522268; Fax 0533-551219).** (1878)A

UNIVERSITY OF GLASGOW
DEPARTMENT OF MEDICINE AND THERAPEUTICS

Post Doctoral Research Fellow

Applications are invited for a three-year post-doctoral appointment to join a team working on the neuropharmacology of epilepsy. Experience with in vitro brain slice techniques and/or neuronal cell culture would be an advantage. The project will involve investigation of the basic mechanisms of epileptogenesis and their amelioration by pharmacotherapy. The position offers scope for liaison with clinical staff and for collaboration with a multi disciplinary research group in neuropharmacology.

The appointment will be on the 1A scale (£10,458 to £13,527 per annum) Applications, including a full C.V. (3 copies) and the names and addresses of two referees, should be sent as soon as possible to **Miss Helen D. Barr, Departmental Administrator, Department of Medicine and Therapeutics, Western Infirmary, Glasgow G11 6NT.**

Further details are available from Dr Martin J. Brodie (041-339-8822 Ext. 4572). (1886)A

YORK UNIVERSITY
Faculty of Arts. Department of Geography.
One position, commencing July 1, 1990, subject to University Approval.

Assistant Professor

Tenure-stream Process Geomorphologist to complement existing programme strengths in the areas of biogeography, climatology, hydrology and quaternary geomorphology. PhD at or near completion is required as well as evidence of a strong research potential and an ability to teach at the undergraduate and graduate level.

York University is implementing a policy of employment equity, including affirmative action for women faculty. In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada.

Applicants should submit a resume and the names of three references by December 15, 1989 to: **Chair, Department of Geography, Faculty of Arts, York University, North York (Toronto), Ontario, Canada M3J 1P3.** (NW4393)A

Novo-Nordisk

Natural Product Chemist

Novo-Nordisk a/s is one of the world's largest leading biotechnology companies. It is a major force in insulin manufacture and diabetes treatment and is the world's largest producer of industrial enzymes. The company also manufactures and markets a variety of other pharmaceutical and bioindustrial products.
Headquartered in Denmark, Novo-Nordisk employs more than 7,500 people in 30 countries and markets its products in 120 countries.
An extensive R&D effort in our laboratories in Denmark, The United States, and Japan is a key to our success in a highly competitive field and a basis for our fore-front position i biotechnology.
By using Novo - Nordisk's strength and experience as one of the world's leading fermentation companies, significant steps are being taken towards development of cost-effective products based on natural organisms.
To a new expansion in our team searching biologically active natural products we now invite applicants with a keen interest in structure determination to strengthen the basis of our structure determination capacity.
We are looking for organic chemists with a very strong background in natural product chemistry besides an interest in structure activity relationships of biomolecules and a general interest in microbiology and biosynthesis. We imagine co-workers with an extensive experience in structure determination and knowledge of state of the art spectroscopic techniques, in particular NMR-spectroscopy. We prefer applicants with a Ph.D. degree and some postgraduate experience as well as a documented scientific background.
We offer an inspiring atmosphere in an exciting scientific environment.
Applications marked"chemist.30"should be forwarded to the Personnel Department.

CHARING CROSS AND WESTMINSTER MEDICAL SCHOOL (University of London)

DEPARTMENT OF ANATOMY

TECHNICIAN

Applications are invited for the above post the holder of which will be required to participate in the running of a busy teaching department and to provide technical assistance in a variety of interesting research projects. Applicants should be qualified to HNC level. Experience in Histology and Electron Microscopy an advantage. Commencing salary within range £7,415-£10,148 p.a. plus £1,267 p.a. London Allowance, according to age and experience. Applications on forms obtainable from **The Secretary, Charing Cross and Westminster Medical School, The Reynolds Building, St. Dunstan's Road, London W6 8RP,** within three weeks of the appearance of this advertisement quoting Ref. No. 89/94. (1855)A

DOMINICA, WINDWARD ISLANDS

Post Harvest Fruit Technologist

The Caribbean island of Dominica is an independent Commonwealth republic.

Based at the Dominica unit of the Caribbean Agricultural Research and Development Institute, you will be working in a multi-disciplinary team of scientists concerned with production and post-harvest problems associated with tropical fruit crops. Your specific duties will be to investigate these problems, collate information to provide an information resource base, and develop technology packages for post-harvest handling, storage and shipping of specified crops. You will also develop and train staff in post-harvest technology and collaborate with the Government of Dominica and other regional agencies and organisations involved in the post-harvest sector.

QUALIFICATIONS

Applicants should possess an MSc or PhD in Horticulture, Crop Physiology, Post-Harvest Physiology or a related Agricultural Science. At least 5 years' post-qualification work experience is required, preferably including work in the area of handling and packaging techniques of tropical fruit for export or commercial disposal.

TERMS OF APPOINTMENT

You will be on contract to the British Government for a period of 3 years. **Salary is in the range of £18,375 p.a. to £26,200 p.a. (UK taxable)** together with variable tax-free overseas allowances currently of £3,049 p.a. (single) and up to £4,830 p.a.(married). Benefits include children's education allowances, free accommodation and passages, and annual fare paid leave.

CORPS OF SPECIALISTS

Vacancies currently exist within the ODA's Corps of Specialists for British subjects in the field of post-harvest fruit technology. A highly satisfactory standard of performance during the above assignment may lead to a longer term appointment, within the Corps of Specialists, of up to 10 years.

For details and application forms, please write quoting job title and ref AH375/DS/N to: Appointments Officer, Overseas Development Administration, AH220, Abercrombie House, Eaglesham Road, EAST KILBRIDE, Glasgow G75 8EA. Or tel 03552 41199 ext 3367.

UNIVERSITY OF TOULOUSE
TOULOUSE-PURPAN HOSPITAL MEDICAL SCHOOL
DEPARTMENT OF CELL BIOLOGY
2 POST DOCTORAL POSITIONS:
PROTEIN BIOCHEMIST/IMMUNOCHEMIST

2 Ph.D. level candidates are sought with experience in:

— either isolation, characterization and purification of cell proteins using both biochemical and immunochemical methods,

— or protein epitope mapping, peptide sequencing, peptide synthesis,

— or both.

In the frame of a collaborative research program with a French biotechnology company, the candidates will join a small group of protein biochemistry working in autoimmunity and studying various human tissular protein antigens. A good background in immunology would be appreciated.

Opportunity for interactions with other basic scientists, including molecular biologists in the university are available.

The posts are for 2 years (2 successive one-year labor contracts). Salary 110 000 FF/Yr to 140 000 FF depending on experience.

A minimum knowledge of French language is required.

These positions are available from November 1st, 1989.

Send full CV including description of research experience and 2 letters of recommendation to: **Dr Guy Serre, Laboratoire de Biologie Cellulaire, C.H.U. PURPAN, Place du Docteur Baylac, 31059 TOULOUSE Cédex — FRANCE.** (W6618)A

THE LONDON HOSPITAL MEDICAL COLLEGE

(University of London)

MLSO IN HISTOPATHOLOGY

Applications for a MLSO in Histopathology are required for the Experimental Pathology Department of the London Hospital Medical College. HNC/TEC pass or an appropriate science degree required, and facilities are available for taking further qualifications. The job entails the assistance with experiments, radioactive isotopes, upkeep and development of computer programs for record keeping, audio visual aids and image analysis. Post vacant immediately.

Salary range MLSO 1 £8,682 to £11,415 inclusive of London Weighting (under review). Application forms are available from the Secretary, The London Hospital Medical College, Turner Street, London E1 2AD (01-377 3010) and should be returned within 21 days of this advertisement. (1860)A

POSTDOCTORAL POSITION

available immediately for a Ph.D. in physical chemistry/biochemistry to study the mechanism of electron transfer reactions of the membrane protein cytochrome P-450. Experience with enzyme kinetics and/or stopped-flow spectrometry helpful. Salary negotiable. Send C.V. and 3 references to: **Dr. L. Waskell, M.D., Ph.D., VA Medical Center, University of California, San Francisco, 4150 Clement Street, San Francisco, CA 94121.** Equal Opportunity Employer/Affirmative Action (NW4417)A

Biological NMR Scientist

The worldwide success of Hoffmann-La Roche results from a fundamental commitment to pioneering Research and Development. At our Research Centre in Welwyn Garden City, there are advanced resources and scientific teams whose work is contributing to the quality of life through developments in healthcare.

The Physical Methods Department of the Chemistry Group now has a need for a scientist, expert in the use of NMR spectroscopy to solve "biological" problems. Examples of these problems will include the determination of protein structure, the elucidation of conformations of drug molecules bound to their receptors and various studies on whole cell preparations.

Ideally you will be a recently qualified Ph.D or post-doctoral scientist fully conversant with the application of NMR theory and practice to the solution of biological problems. You will be expected to seek out NMR based solutions to drug-research problems and will therefore require a high degree of creativity. Excellent communication skills are essential in order to interact fully with the biologists, medicinal chemists, molecular graphics experts and other scientists in the multidisciplinary environment at Roche.

The facilities in our Welwyn Research Centre are first class. We have 250, 300 and 400 MHz spectrometers together with access to 500 MHz spectrometers and protein X-ray crystallography within the international organisation.

In return for your commitment and scientific contribution, you will receive the benefits associated with a progressive organisation of international repute including sound career and salary progression.

For a more detailed informal discussion please contact Dr. W. A. Thomas on Welwyn Garden City **(0707) 328128, ext. 2545**. Alternatively send a comprehensive C.V. to **Maxine Lambert, Roche Products Ltd, P.O. Box 8, Welwyn Garden City, Herts AL7 3AY.**

ROCHE

Queen's Award for Export Achievement for 1987

(1877)A

UNIVERSITY OF GLASGOW
ROBERTSON INSTITUTE OF BIOTECHNOLOGY
DEPARTMENT OF GENETICS

LECTURESHIP IN BIOTECHNOLOGY

Applications are invited for a University Lectureship in Biotechnology in the Robertson Institute of Biotechnology within the Department of Genetics. The Robertson Institute is being built adjacent to the Institute of Genetics and will share facilities with it. The Intitute was created by a recent generous benefaction and will house the Robertson Professor of Biotechnology (Professor R W. Davies) and three University biotechnology lecturers (including the successful applicant).

Applicants should have a proven research record in an area that augments the research activities of the biotechnologists and geneticists within the Department Applications from those with an existing or planned research programme using higher organisms in a Health-Care related field, would be particularly welcome. The Department is very active and well equipped for research in molecular genetics using a variety of microbial and animal systems and will shortly have a facility for work with transgenic animals. The major areas of research by the biotechnology staff are: applied molecular neurobiology (Professor R.W Davies); differential gene expression in animal systems (Dr. K. Kaiser); and gene expression and secondary metabolism in *Streptomyces* (Dr. I.S. Hunter).

Salary will be within the range £10,458 - £20,469 on the Lecturers' scale with placement according to age, qualifications and experience. Informal enquiries may be made to Professor Davies, Professor Sherratt or Dr. Sutcliffe, Department of Genetics (Tel· 041-330 5113).

Further particulars can be obtained from the Academic Personnel Office, University of Glasgow, Glasgow, G12 8QQ, where applications (8 copies), a short research proposal and the names and addresses of three referees, should be lodged on or before 15th November, 1989. In reply please quote Ref No. 6730. (1897)A

SCOTTISH CROP RESEARCH INSTITUTE
Invergowrie, Dundee DD2 5DA

MOLECULAR BIOLOGIST/VIROLOGIST SCIENTIFIC OFFICER (BAND I)/ HIGHER SCIENTIFIC OFFICER (BAND I)

3 year appointment
VIROLOGY DEPARTMENT

Applications are invited for a post, funded by the Overseas Development Natural Resources Institute, for research on the molecular properties of viruses associated with groundnut (peanut) rosette disease, one of the most important plant diseases in Africa. The disease is caused by a satellite RNA associated with groundnut rosette virus, and both these agents depend on groundnut rosette assistor virus for transmission by aphids. Variants of the satellite are known that induce different symptoms in groundnut and other plants The aim is to determine the sequences, homologies and biological functions of the various RNA species, and to develop diagnostic probes.

Appointment at HSO will be preferred but if necessary a less experienced person may be appointed at SO, with an opportunity to register for a higher degree.

Salary: SO: £9,131-£12,223
HSO· £10,678-£14,909

Non-contributory superannuation.

Qualifications:

SO: First or upper second class honours degree, or a qualification of equivalent standing, in a relevant scientific discipline.

HSO: First or upper second class honours degree, or a qualification of equivalent standing, in a relevant scientific discipline, with at least three years' relevant post-qualifying experience

The Institute is an equal opportunities employer.

Further particulars can be obtained from **Mr I Paxton, Personnel Officer** to whom application with a *curriculum vitae* and the names and addresses of at least two referees should be sent by 9th November 1989, quoting the reference VIR/2/89 (1899)A

RESEARCH FELLOW
(MATERIALS SCIENTIST)

$30,000 – $43,861

DIVISION OF MATERIALS SCIENCE AND TECHNOLOGY
CLAYTON, VICTORIA

The Division of Materials Science and Technology works closely with Australian industry to prepare and develop new materials processes and instruments for a variety of emerging industrial technologies The Division has major programs involving alloys research, ceramic research, advanced materials and solid state science, and is located in the CSIRO complex at Clayton, Victoria, adjacent to Monash University The Division has professional staff with skills encompassing most of the physical sciences and an excellent range of instrumental facilities, together with first class library and support facilities

The Division is seeking an enthusiastic scientist to undertake research into the electrical and electrochemical properties of ceramics of potential interest to Australian industry

The research responsibilities involve

- investigation of charge transport processes across electrode/electrolyte interfaces and within solid electrolytes.
- electrode and electrolyte preparation techniques
- design and fabrication of solid electrolyte cells and prototype testing of specific devices, with the possibility of industrial trials

The necessary qualifications and qualities

- Ph D. degree or equivalent in Chemistry, Electrochemistry, Chemical Engineering, Materials Science, Materials Engineering, Physics or Metallurgy
- initiative and proven ability to conduct research in solid state ionics, electrical ceramics or a closely related field
- good knowledge of basic electrochemistry techniques
- preferably experience in ceramic processing, thin or thick film technology or computing

Prospective applicants are invited to telephone Dr S Badwal on (03) 542 2719 for further information

CONDITIONS: Appointment will be for three years, with Australian Government Superannuation benefits available The detailed job description and selection criteria can be obtained from Ms Fazzari on 542 2807 or fax number (03) 544 1128

APPLICATIONS: Applications should be submitted by November 24 1989 and quote reference No AA186T Applications should relate to the selection criteria, and should provide details of relevant personal particulars including qualifications and experience, and the names of at least two professional referees and be addressed to

The Chief,
CSIRO Division of Materials Science and Technology
Locked Bag 33,
Clayton, Victoria, 3168.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER TR 89/71

SOUTH EAST THAMES REGIONAL CYTOGENETICS LABORATORY
GUY'S HOSPITAL

CYTOGENETICIST
BASIC OR SENIOR GRADE SCIENTIFIC OFFICER

This is a busy centre, providing pre and post natal screening for chromosome disorders Cytogenetics at Guy's Hospital is an integral part of the Division of Molecular and Clinical Genetics, which embraces a range of disciplines, including biochemical genetics and recombinant DNA work.

For the senior post you should have several years' experience in human cytogenetics, and will be expected to take a responsible role in helping to run the diagnostic services.

For the Basic Grade post you should have a good honours degree in genetics or other biological subject. Previous experience in cytogenetics is always welcome, but not essential, and full training will be given in all aspects of work, which includes tissue culture and microscopy.

Further information may be obtained from Dr. Michael Daker or Dr Zoe Docherty on 01-955 4448 or 01-955 5000 extension 2542 respectively

Applications including full C V and the name of two referees should be sent to the Personnel Officer, Guy's Hospital, St Thomas Street, London, SE1 9RT.

Closing date. 3rd November 1989.

Aiming to be an Equal Opportunities Employer. (1881)A

LABORATORY OF MOLECULAR BIOPHYSICS
UNIVERSITY OF OXFORD
Director of Computing

Applications are invited for the above Departmental Research Assistant Post at Grade RSII (Salary scale £15,372–£20,469). The Laboratory of Molecular Biophysics, in association with the Oxford Centre for Molecular Sciences, is well equipped with state-of-the-art computing facilities which are used in a concerted programme of structural studies of biological macromolecules The facilities include

a Convex C210; a large VAX cluster, comprising a VAX 6210 and a number of microVaxes and VAX workstations; and 3 Evans & Sutherland Computer Graphics Systems.

The Director is required to manage this resource with the help of a RSIA and to plan futher developments. The successful applicant will also be expected to develop a research programme, either independently or in collaboration with others, and to contribute to teaching.

Applicants should have experience in computer programming and some aspects of protein crystallography.

Applications, enclosing cv and the names of 3 referees, should be sent to **Dr L N Johnson, c/o Mrs P Batchelor, Laboratory of Molecular Biophysics, Rex Richards Building, South Parks Road, Oxford, OX1 3QU** by 17 November 1989.

The University is an Equal Opportunity Employer. (1873)A

UNIVERSITY OF OXFORD

TITULAR UNIVERSITY LECTURESHIP IN PHYSIOLOGY

in association with

OFFICIAL FELLOWSHIP AT ST. JOHN'S COLLEGE

Applications are invited from candidates who have specialised in any area of Physiology or related disciplines for a Titular University Lectureship in Physiology, in association with an Official Fellowship at St. John's College, tenable from 1st October 1990 The full stipend associated with the Titular University Lectureship will be met by the College; and the title may be at a later date (though with no commitment to do so) be converted into a stipendiary University post.

Further details may be obtained from **Professor Colin Blakemore, University Laboratory of Physiology, Parks Road, Oxford OX1 3PT,** to whom applications (thirteen typescript copies or, in the case of overseas candidates, one copy) — to include a full curriculum vitae, list of publications, and a statement of research interests and teaching experience — should be sent by 15th December 1989, together with the names of three referees who have agreed to send their opinions without further requests by the same date. (1872)A

Klinikum der Universität Heidelberg

The Zentrum für Molekulare Biologie Heidelberg (ZMBH) at the University of Heidelberg (FRG) invites applications for a five year

GROUP LEADER POSITION

The successful candidate will have the opportunity to establish an independent research group. It is expected that his research program will contribute to the ZMBH's research activities which focus on

— regulation of gene activity and differentation,
— molecular neurobiology,
— molecular mechanisms of pathogenicity.

The holder of the position will also be entitled to participate in the department's teaching program.

The ZMBH presently houses 16 independent research groups and offers excellent central facilities which include DNA- and peptide synthesis, protein microsequencing, FACS, animal quarters and centralised administrative services.

Applications should be sent to the **Direktor of the ZMBH, Im Neuenheimer Feld 282, D-6900 Heidelberg, FRG, by 30 November 1989.** (W6622)A

DOCTORAL STUDIES IN BIOLOGY AND MOLECULAR BIOLOGY

The Department of Biological Sciences of the University of Maryland Baltimore County offers courses of study leading to Ph.D. degrees in Biological Sciences, Molecular and Cell Biology and Marine Estuarine-Environmental Studies The research interests of the 25 faculty of the Department include microbiology, molecular biology of prokaryotes and eukaryotes, plant biology, genetics, cell and developmental biology, physiology, ecology and evolution The Department is equipped with state-of-the-art facilities for modern research in biology, and is located in the most rapidly growing campus of the University of Maryland system. Graduate assistantships offered to incoming students include a stipend and remission of tuition. To obtain an application form and further information please write to·

Dr Paul S. Lovett

MICROBIAL MOLECULAR BIOLOGY
UNIVERSITY OF SOUTHERN CALIFORNIA

The Molecular Biology Section of the Department of Biological Sciences invites applications for one

TENURE-TRACK FACULTY POSITION
at a JUNIOR or SENIOR level

The successful candidate will be expected to establish and maintain a vigorous, independent research program in Microbial Molecular Biology. The candidate will also be expected to participate in the teaching programs of the Department at the undergraduate and graduate level, and to participate in the further development of the Molecular Biology Section.

Applicants should send a current curriculum vitae, a statement of research plans, and the names of three references by November 30, 1989 to:

Search Committee "M" Chairman
Molecular Biology Section
SHS 172, MC 1340
University of Southern California
Los Angeles, CA 90089-1340

The University of Southern California is an Equal Opportunity Employer. (NW4401)A

FACULTY POSITION IN PROCARYOTIC MOLECULAR BIOLOGY

The Center of Marine Biotechnology of the Maryland Biotechnology Institute, University of Maryland System, invites applications from outstanding candidates to occupy a full-time, tenure track faculty position

(Assistant or Associate Professor)

in procaryotic molecular biology Prior work in marine systems is an advantage, but not essential. The successful candidate will be expected to foster independent research programs in one of the following general areas: 1. Molecular ecology, with an emphasis on microbial diversity in communities; 2. Archaebacterial molecular biology; 3. Biochemical and genetic aspects of photosynthetic bacteria. Many opportunities exist for collaborative research at the Center of Marine Biotechnology, and many of the faculty hold joint appointments with nearby teaching units

Candidates must have a PhD and a minimum of two years postdoctoral experience. To apply, submit a letter of application, curriculum vitae, brief description of current research and research plans, and names and addresses of three references to: **Procaryotic Molecular Biology Search Committee, Center of Marine Biotechnology, 600 E Lombard Street, Baltimore, MD 21202, USA.** For best consideration, applications should be received before January 31, 1990, but they will be accepted until the position is filled.

The University of Maryland System is an Equal Opportunity, Affirmative Action employer. (NW4395)A

LIFE SCIENTISTS & CHEMISTS

cpl SCIENTIFIC

Top quality scientists and laboratory technicians in the following disciplines are required for short-term and permanent positions in a variety of laboratories throughout the United Kingdom:

- ⋆ CHEMISTRY
- ⋆ TOXICOLOGY
- ⋆ FOOD SCIENCE
- ⋆ BIOCHEMISTRY
- ⋆ PHARMACOLOGY
- ⋆ MICROBIOLOGY

DEPARTMENT OF BIOLOGY

POST-DOCTORAL MOLECULAR BIOLOGIST/PARASITOLOGIST

Required for three years, on an AFRC funded project commencing January 1990, to map immunodominant regions of an antigen of parasite origin with a view to synthetic vaccine development The project will involve achieving expression of a cloned surface antigen gene (from a protozoan cattle parasite *Theileria annulata*) in a suitable system, followed by purification of the product, for use as an immunogen. The work will involve all standard recombinant DNA techniques, plus the use of a variety of immunochemical assays. This is a collaborative project with Professor A Tait of The Wellcome Unit of Molecular Parasitology, University of Glasgow.

Salary within the range: £10,548-£12,381 per annum.

Informal enquiries may be made to Dr R Hall (tel: 0904 432815).

Three copies of applications, giving full details of qualifications and experience and naming two referees, should be sent to the Personnel Office, University of York, Heslington, York YO1 5DD, by 10 November 1989. Further particulars are available. Please quote ref: 6/6276.

(1853)A

UNIVERSITY OF YORK

UNIVERSITY OF ABERDEEN
RESEARCH POSITION IN MARINE BIOLOGY/FISHERIES

A postdoctoral research worker is required for a large collaborative project on the biology and fishery of north east Atlantic squid.

The work will involve data collection from commercial sources and research vessel cruises and the application of analytical methods to stock morphometrics, reproductive seasonality and population biology. Applicants should possess strong numerical and computational skills and have fisheries-related experience. The post will involve organising large data banks, co-ordination between collaborating groups in UK, Spain and Portugal and ability to manage a major project. A technician post is available to support the practical work. The project is funded by the European Commission for 3 years, starting 1 January 1990, and the salary will be within the range £10,458-£16,665

Further details on the project may be obtained by telephoning Professor P R Boyle on 0224 272865. Applications by letter with CV including the names of three referees to the **Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX** by 10 November 1989 quoting reference number LW/061 (1870)A

GRADUATE PHARMACOLOGIST/ PHYSIOLOGIST

Organon is a major ethical pharmaceutical Company, part of the international Akzo organisation. Our continuing programme of development means that the Scientific Development Group now requires a Pharmacologist/ Physiolgist, ideally with an interest in the biochemistry and physiology of airways disorders. Some expertise in the investigation of compounds in animal models of relevance for asthma would also be advantageous.

You should have recently qualified with a good first degree.

In return, we offer an attractive salary, and conditions of employment are in line with the best modern practice.

For further details telephone Dr. C.D. Nicholson, Head of Pharmacology Department, on Holytown (0698) 732611 ext. 292. Please apply in writing, enclosing a comprehensive C.V., to: The Personnel Manager, Organon Laboratories Limited, Newhouse, Lanarkshire, ML1 5SH

FACULTY POSITIONS IN EUKARYOTIC MOLECULAR BIOLOGY

The Center of Marine Biotechnology of the Maryland Biotechnology Institute, University of Maryland System, is seeking outstanding candidates to fill full-time tenure-track positions

(Assistant Professor to Full Professor)

in eukaryotic molecular biology. Experience with marine organisms is desirable but not essential.

The successful candidates will be expected to establish independent research programs in, or related to, the following areas: molecular basis of growth, development, and reproduction of fish, shellfish or algae; endocrinology; molecular basis of marine symbiotic relationships; and sex determination. Many opportunities exist for collaborative research at the Center of Marine Biotechnology.

Candidates must have a Ph.D. and a minimum of two years of post-doctoral experience. Applicants should submit a letter of application, curriculum vitae, statement of ongoing research, a brief description of research plans, and the names and addresses of three references to: **Search Committee, Center of Marine Biotechnology, 600 East Lombard Street, Baltimore, Maryland 21202.** For best consideration, applications should be received before December 1, 1989.

The University of Maryland System is an equal opportunity, affirmative action employer. (NW4406)A

PROFESSOR OF BIOCHEMISTRY AND CHAIR DEPARTMENT OF BIOCHEMISTRY SCHOOL OF MEDICINE, EAST CAROLINA UNIVERSITY

Nominations and applications are invited for the position of Professor and Chairperson of the Department of Biochemistry at the East Carolina University School of Medicine. The department is responsible for the education of medical and graduate students and consists of 9 tenured or tenured-track faculty. The department is well-funded and well-equipped. We are seeking candidates with an outstanding record of achievement in any field of biochemistry or molecular biology to provide strong leadership to an excellent department. Candidates should have a doctorate in biochemistry or a related discipline, experience in an academic medical center and a record of scientific excellence. Candidates should submit a curriculum vitae and the names and addresses of three references to: **Dr. Wallace R. Wooles, Chairman, Biochemistry Search Committee, Department of Pharmacology, East Carolina University School of Medicine, Greenville, North Carolina 27858.** Applications should be received by February 1, 1990. East Carolina University is an Equal Opportunity Employer and encourages the application of women and minorities. (NW4409)A

Applications are invited for two tenure track positions available for September 1990. The positions are at the assistant professor level. We are particularly interested in candidates who specialise in

"a synthetic and experimental approach to the study of vertebrate reproductive biology"

"molecular biology of the nervous system and behaviour, with strong developmental and/or genetic components"

Please submit curriculum vitae (including biographic data), short statement of research objectives, names of at least 5 referees, and selected reprints to **The Chairman, Department of Zoology, University of Texas, Austin, TX 78712-1064, USA, before January 1, 1990.**

THE UNIVERSITY OF TEXAS AT AUSTIN IS AN EQUAL OPPORTUNITY/AFFIRMATIVE ACTION EMPLOYER. (NW4402)A

CHAIR
MOLECULAR AND HUMAN GENETICS EMORY UNIVERSITY

The School of Medicine seeks a Professor and Chairperson for a new Department of Molecular and Human Genetics. Emory has an established genetics research group, and an interdepartmental Graduate Program in Genetics and Molecular Biology. The School of Medicine is now forming a new basic medical science department, with several additional positions and significant new laboratory space. Nominations or curriculum vitae will be considered until December 1, 1989 or until the position is filled Please submit them to: **Dr. Robert B. Gunn, Chairman of Search Committee, 302 WHSCAB, Emory University School of Medicine, Atlanta, GA 30322.**

Emory University is an equal opportunity employer. (NW4373)A

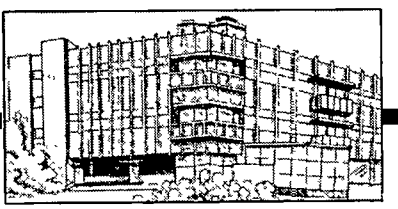
ELSEVIER SCIENCE PUBLISHERS LIMITED



EDITOR
TRENDS IN BIOTECHNOLOGY

Elsevier Trends Journals is the Cambridge-based Division of the International Elsevier Science Publishers Group, one of the world's largest scientific, technical and medical publishers. At our Cambridge office we are seeking a full-time Editor for our monthly review journal **Trends in Biotechnology**.

A leading member of the Trends family of journals, Trends in Biotechnology publishes reviews and other features covering all aspects of biotechnology. Applicants should have a thorough grasp of the major scientific and technical advances driving biotechnology, an understanding of the information needs of those interested in the field and the ability to communicate with scientists in industry and academe. Applicants will usually have a post graduate qualification in a relevant field. Publishing experience, although an advantage, is not required but a willingness to learn publishing skills is essential.

An attractive salary is offered and benefits include 5 weeks annual holiday, pension scheme and assistance with relocation expenses where appropriate.

To apply, please send your c.v. plus a covering letter to **Dr. David Bousfield, Publisher, Elsevier Trends Journals, 68 Hills Road, Cambridge CB2 1LA, U.K.** (Telephone 0223 315961). Closing date for applications 3rd November 1989. (1905)A

MERRELL DOW RESEARCH INSTITUTE

Invites applications for a

Group Leader
Development Chemistry

The Merrell Dow Research Institute is engaged in the discovery and development of novel therapeutic agents in centers located in the USA, Japan, Italy, U K and France The Institute has a strong potential in France with its fundamental research center in Strasbourg and development group in Limay (near Paris)

The Limay group produces compounds selected for pre-clinical and clinical studies in Europe and in the USA We are seeking an experienced candidate to assume responsibility for directing this research group composed of 17 employees (senior scientists, technicians and operators)

The group leader coordinates the production of the required supplies for the development programs He adapts existing processes and assists production by solving manufacturing problems of new compounds He interacts in the organization with the basic research centers in Strasbourg, France, and in Cincinnati, USA

The candidate should have a strong background in organic chemistry and chemical engineering with accomplishments in the general area of development chemistry Demonstrated ability for leadership is required as well as good practical ability in both the English and French languages

We offer excellent compensation and benefits package

Please forward your resume and names of three referees to Mrs M.J. Bildstein, Human Resources Merrell Dow Research Institute, BP 447 R/9, 16 rue d'Ankara, 67009 Strasbourg Cedex

Research Assistant Professor Position

Clinical Mass Spectrometry Division, Department of Pediatrics

A Research Assistant Professor position is available in the Clinical Mass Spectrometry Division of the Department of Pediatrics, Children's Hospital Medical Center, University of Cincinnati, College of Medicine. The group is engaged in the application of the latest mass spectrometric techniques to clinically related projects, with a specific focus on steroid and bile acid metabolism. The candidate will participate in the teaching and training of research fellows and assistants in mass spectrometry, be expected to provide support to the group in running and monitoring instrumentation and be expected to independently develop further a program on vitamin D metabolism (in conjunction with the Division of Neonatology) by utilizing stable-isotopes of vitamin D to study the kinetics and disposition of vitamin D in the pre- and perinatal period in animal models and in man.

The Division is equipped with a Finnigan 4635 GC-MS-DS instrument with EI, CI and FAB ionization modes, a Vestec 201 thermospray LC-MS system and is soon to acquire a high resolution magnetic sector instrument. The candidate must have a PhD degree and at least 5 years' prior expertise in the operation and maintenance of mass spectrometry instrumentation and vacuum systems, and hands-on experience of the thermospray LC-MS technique which will be utilized extensively in these studies. Experience in the use of stable-isotopes for analytical and pharmacokinetic studies, and expertise in chromatographic procedures for the analysis of steroids and vitamin D and its metabolites in biological fluids is essential.

The position reports to Director, Clinical Mass Spectrometry. Resumes may be submitted to:

THE WELLESLEY HOSPITAL RESEARCH INSTITUTE AND DEPARTMENT OF IMMUNOLOGY
UNIVERSITY OF TORONTO

Applications are invited for the position of

LEADER

of a new basic research initiative to investigate cellular and molecular aspects of immunoregulation and autoimmunity.

Funding is available for a leader and 3 additional positions at the

Assistant or Associate Professor (Ph.D or M.D.)

level. Applicants (Ph.D or M.D.) for the program leader at the Associate or full Professor level are sought. The leader will be responsible for recruiting the additional 3 individuals. Salary commensurate with experience. The Institute will provide ample space and generous start-up funds in addition to substantial ongoing administrative funding. Consideration in the first instance will be given to Canadians. Application deadline is January 1, 1990.

Enquiries and curriculum vitae should be directed to **Dr. E. C. Keystone, c/o Research Office, The Wellesley Hospital, University of Toronto, 160 Wellesley St. East, Toronto, Canada M4Y 1J3.** (NW4397)A

UNIVERSITY OF BRISTOL
Department of Medicine (Rheumatology)

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a 3 year Postdoctoral Research Fellowship with Professor Paul Dieppe (Bristol University) and Dr. Brigid Heywood (Bath University) on the macromolecular control of pathological calcification. The project is funded by the Arthritis and Rheumatism Council, and includes a full time technician dedicated to this work. The work will explore the hypothesis that biological macromolecules, including serum proteins, control the growth and formation of calcium phosphates in diseased tissue. It will involve protein separation, characterisation and crystal growth experiments. Applicants should have a PhD and experience in protein chemistry or a related, relevant discipline. The starting salary will be in the range £9,865 - £12,760 pa depending on qualifications and experience. Two copies of applications, including full c.v. and the names of two referees, should be sent to Prof. P. Dieppe, Rheumatology Unit, Bristol Royal Infirmary, Bristol BS2 8HW by 30th November 1989. Further details can also be obtained from Dr. B. Heywood, Bio-inorganic Chemistry Laboratory, University of Bath, Bath BA2 7AY (Tel 0225 826826 ext 5508) (1868)A

INSTITUTE OF OPHTHALMOLOGY
DEPARTMENT OF PATHOLOGY

POSTDOCTORAL RESEARCH ASSISTANT OR GRADUATE

An assistant is required to investigate fundamental and applied aspects of *scar tissue* formation within the eye relating to retinal detachment.

The position involves tissue culture and morphological work and would be suitable for candidates with interests in cell biology, biochemistry or electron microscopy.

The appointment will be initially for 1½ years and can be made either at the graduate (upper second or above in a biological science) or postdoctoral level within the starting range £9,816–£11,736 plus £1,650 London Allowance depending on qualifications and experience.

Applications with cv and the names and addresses of two referees should be sent to **Professor Ian Grierson, Department of Pathology, Institute of Ophthalmology, 17–25 Cayton Street, London, EC1V 9AT.** (1861)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
ACADEMIC DEPARTMENT OF MEDICINE

RESEARCH ASSISTANT

Applications are invited for a Wellcome Trust supported 3 year post to apply molecular biology and genetic techniques to the study of hereditary haemochromatosis. The work will involve the isolation and characterisation of candidate genes and gene mapping by pulse field gel electrophoresis, and linkage studies. There is excellent clinical support for this project. This post is suitable for either a recently qualified PhD or a graduate research assistant with at least two years' experience. Candidates should have a background in Biological Sciences or Biochemistry. Salary will be within Research Range 1A or 1B as appropriate plus £1,650 London Allowance. Full job description available from the **School Office, R.F.H.S.M., Rowland Hill Street, London NW3 2PF (Tel: 01-794 0500 Ext: 4262)** to which applications (**three copies** of curriculum vitae plus names and addresses of two referees) should be sent by **4th NOVEMBER 1989,** quoting Ref: **MED/RA/44.** (1856)A

A LARGE PHARMACEUTICAL RESEARCH CENTER in suburban PARIS is recruiting a

SPECIALIST

in the pharmacology of rheumatic diseases

to be responsible for the development and supervision of experimental models of pathologies necessary for innovation in the fields of bone metabolism, inflammation and pain

A Doctorat or Ph.D (or equivalent) in pharmacology is required
Experience in an industrial setting will be an asset, but above all the successful candidate will demonstrate the desire to apply himself or herself to the fascinating and challenging problems in these fields

Please send your C.V accompanied by a statement of your professional aspirations to *PUBLIVAL/9149* - 27, Route des Gardes 92190 MEUDON (FRANCE) (W6627)A

University of Cambridge
Department of Applied Mathematics and Theoretical Physics
Departmental Secretary

To take responsibility for financial and related administrative matters, extensive external research grants and contracts held by the Department. He (or she) will also have duties in relation to the Faculty of Mathematics, in particular the Secretaryship of the Faculty Board of Mathematics. The preferred applicant will be expected to have a science-based background and administrative and/or research experience. The work will involve interaction with all the teaching and research staff of the Department, the University Central Offices, and external bodies, such as SERC.
The appointment will be for three years in the first instance with the possibility of reappointment to the retiring age The pensionable scale of stipends for a Departmental Secretary (Grade B), not ordinarily resident in College, is £14,169 a year, rising by eleven annual increments to £21,852.
Further information may be obtained from **Dr. M. J. Horne, Secretary of the Appointments Committee for Departmental Secretaries, General Board Office, The Old Schools, Cambridge CB2 1TT,** to whom completed applications (ten copies), including a *curriculum vitae* and the names of not more than three referees, should be sent so as to reach him not later than 1st November 1989. DEPUTY HEAD, SCIENCE AND ENGINEERING SYSTEMS DIVISION

The Space Telescope Science Institute offers you the opportunity to contribute to one of the greatest scientific enterprises of the decades. An international center for research in Astronomy, we will be responsible for the scientific operation and systems support of the Hubble Space Telescope.

The Institute is looking for a Deputy Head of the Science and Engineering Systems Division. This Division of the ST ScI has the responsibility for the development and augmentation of science operations capabilities of the Hubble Space Telescope. Activities include developing in-depth understanding of the capabilities of the flight hardware and software, developing science operations concepts for use of these capabilities in support of the HST mission, carrying out system engineering studies and allocating requirements to ground system elements, and actual implementation of those ground system elements allocated to the ST ScI During flight operations, the Division will also be responsible for engineering analyses and recommendations for improving overall observing efficiency. The ST ScI ground system elements which are the Division's direct responsibility include the proposal entry and processing system, long-range and short-range observation scheduling systems, and real-time and post facto data processing systems Both traditional and state-of-the-art methodologies are used in these systems. The Division consists of six branches with a total staff of some 90 scientists, engineers, and software professionals.

This position requires a candidate with substantial direct experience in the development and operation of complex scientific hardware/software systems A Ph D. scientist with a strong physics or astronomy background, previous research record, and prior scientific/technical management experience is required A background in space-based scientific operations is desirable

Please submit resume, bibliography and the names of three persons who can be contacted for professional references to Mr. Robert Teleky, Personnel Officer, Space Telescope Science Institute, 3700 San Martin Drive, Baltimore, Maryland 21218. ST ScI is an equal opportunity/affirmative action employer Minorities and females are strongly urged to apply M/F/H/V

RESEARCH ASSOCIATE IN CLINICAL DATA ANALYSIS

Applications are invited for a Grade 1B/1A research associateship for a period of one year, in the first instance, commencing October/ November 1989 Applicants should have a good Honours degree in a bioscience, mathematical or computer science discipline. Candidates with a knowledge and interest in analysis of clinical data bases would be particularly welcomed. The project will involve the interrogation of veterinary clinical data bases with a view to establishing base line parameters and offers scope to explore the use of artificial intelligence techniques. The appointee will collaborate with research workers in the Department of Veterinary Medicine, University of Glasgow and Vettest UK Ltd Applicants should provide a curriculum vitae and the names and addresses of 2 referees.

Further details may be obtained by contacting Professor Max Murray, Veterinary Medicine, University of Glasgow, Glasgow, Tel No: 041-339 8855 or Dr Gettinby, Department of Statistics, University of Strathclyde, Tel No: 041-552 4400. (1893)A

FU BERLIN

An der Freien Universitat Berlin ist folgende Stelle zu besetzen:

Fachbereich Geowissenschaften
— Institut fur Geographische Wissenschaften — FR Physicsche Geographie —

Universitätsprofessor/in C 3 für Physische Geographie

Aufgabengebiet: Physische Geographie mit besonderer Beruchsichtigung angewandter Aspekte aus dem Bereich der Geoökologie und/ oder Quartarforschung. Intensive Mitarbeit in der Ausbildung einschließlich Gelande- und Laboratoriumspraktika, Statistik.

Einstellungsvoraussetzungen: § 100 BerlHG Es wird erwartet, daß der/die zukunftige Stelleninhaber/in an am Institut bestehenden Arbeitsgruppen mitarbeitet und Drittmittel einwirbt. Bewerbungen mit den ublichen Unterlagen sind innerhalb von 4 Wochen unter Angabe der Kennziffer 056 485 zu richten an die Freie Universität Berlin, Fachberiech Geowissenschaften, Podbielskiallee 62, D-1000 Berlin 33. (W6619)A

MASSACHUSETTS INSTITUTE OF TECHNOLOGY
FLANETARY SCIENCE FACULTY
The Department of Earth, Atmospheric, and Planetary Sciences at MIT
expects to make as many as

Two Faculty Appointments

in Planetary Science, beginning as early as the fall semester of 1990 Rank and salary are open, but we particularly encourage potential junior faculty to apply Applications are invited from scientists working in any area of planetary science; the areas of planetary physics and planetary chemistry are of particular interest Existing faculty specialize in observational and theoretical studies of planetary rings, asteroids, radio and radar observations of bodies in the inner solar system, dynamics of the solar system, VLBI geodesy, chemistry and dynamics of planetary atmospheres and tectonics of the terrestrial planets Facilities available include the 1.3m and 2.4m optical telescopes of the McGraw Hill Observatory in Arizona, the Wallace Astrophysical and Haystack Radio Observatories, both in Westford, Mass., and numerous on-campus computers. The successful applicant would be expected to share in the teaching responsibilities of the department. Interested individuals should send a curriculum vitae, list of publications, and the names of three references to: **Dr. T. H. Jordan, Chairman, Department of Earth, Atmospheric and Planetary Sciences, Bldg. 54-918, MIT, 77 Massachusetts Avenue, Cambridge, MA 02139,** by December 15, 1989. *MIT is an equal opportunity/affirmative action employer* (NW4403)A

Neuroanatomist/ Experimental Neuropathologist

Independent research faculty position in the Neuroscience Program at the Maryland Psychiatric Research Center. Experience with modern neuroanatomical techniques required, interest in psychiatric disorders desirable. New EM faculty and generous start-up provided.
Please send CV, a brief outline of research plans and names of at least three references to **Robert Schwarcz, Ph.D. Maryland Psychiatric Research Centre, P.O. Box 21247, Baltimore, Maryland 21228.** (NW4396)A

FOSTDOCTORAL POSITIONS
are available to work on the function of three new human small nuclear RNAs for which we have cloned cDNAs.
Send CV and names of three references to Dr. George Eliceiri, Pathology Dept., St. Louis University Medical School, 1402 S. Grand, St. Louis MO 63104.
Equal Opportunity Employer M/F/H/V
(NW4421)A

UNIVERSITY OF GLASGOW
INSTITUTE OF PHYSIOLOGY
Applications are invited for a grant funded three year Post Doctoral Research post to study mechanisms of electrolyte and fluid transport in normal and anhidrotic equine sweat glands. Experience of techniques in the study of epithelial transport, including radio-isotopic tracer, and/or organ culture techniques would be an advantage. Appointment on grade A scale up to £14,169 starting salary, according to age and experience. Applications, with C.V. and names of two referees by 2nd Nov 1989 to **Dr H.Y. Elder, Institute of Physiology, University of Glasgow, Glasgow G12 8QQ.**
(1863)A

MEMBRANE BIOCHEMIST

Tenure-track, Assistant Professor position, beginning August, 1990. Duties: to develop an active research program in membrane biochemistry and teach graduate and undergraduate level courses Ph.D. and postdoctoral experience required. Salary range $32-36,000/9 Mo
Send statement of current research pursuits, future research goals, C.V. and reprints and have 3 letters of recommendation sent separately to: **Dr. Paul A. Kitos, Department of Biochemistry, 3038 Haworth Hall, The University of Kansas, Lawrence, KS 66045-2106** Consideration of applications will commence November 1, 1989, but applications will be accepted until July 30, 1990, or until the position is filled.
The University of Kansas is an EO/AA employer. (NW4408)A

FACULTY POSITION IN DEVELOPMENTAL BIOLOGY
The Department of Biology at the University of Virginia invites applications from developmental biologists who use cellular and/or molecular genetic approaches to study fundamental problems in developmental biology. We anticipate appointment at the associate or full professor level, although candidates at the assistant professor level will be considered. Send resume and description of research program to **Developmental Biology Search Committee, Department of Biology, University of Virginia, Charlottesville, VA 22901.** Applications will be reviewed beginning November 1, 1989 Equal Opportunity Affirmative Action Employment. (NW4327)A

COMPUTATIONAL NEUROSCIENCE faculty position

The Mahoney Institute of Neurological Sciences (INS) at the University of Pennsylvania invites applications and nominations for a tenure-track faculty position (Assistant or Associate Professor level) in the general area of Computational Neuroscience. Candidates should be able to demonstrate excellence, originality and independence in research, as well as to have some experience in teaching.
The Institute is a University-wide interdepartmental unit that includes more than 90 faculty members and operates a PhD program in Neuroscience. The new faculty member will hold a joint appointment in the Institute and in one or more standing University departments
Candidates should (by December 15, 1989) send a curriculum vitae, a statement of current research interests, copies of recent relevant publications, and the names of three or more individuals willing to provide letters of reference to Professor **George L. Gerstein, Computational Neuroscience Search, Department of Physiology, University of Pennsylvania, Philadelphia, PA 19104-6085.** *Equal opportunity/affirmative action employer.* (NW4413)A

RESEARCH ASSOCIATE

Brigham & Women's Hospital has an opening for a research associate to study electrophysiology of smooth muscle. Applicant should have experience with in-vivo experimentation, chronic animal preparations and basic physiological techniques. Experience with patch clamp technique welcome
Candidates should have a Ph.D in a related field and capacity for interdisciplinary research and growth. Please send resume, letter of interest and names of references to: **D.S Sugarbaker, M.D., Department of Surgery, Brigham & Women's Hospital, 75 Francis Street, Boston, MA 02115.** (NW4404)A

POSTDOCTORAL POSITION
available to study the processing of natural and recombinant neuroendocrine proteins. Protein and peptide chemistry, anti-peptide antibodies, mass spectrometry, molecular biology and cell culture will be used. Send curriculum vitae and names of two references to: **Dr. Ruth Hogue Angeletti, Developmental Biology & Cancer, Albert Einstein College of Medicine, 1300 Morris Park Avenue, Bronx, NY 10461.** *Equal Opportunity Employer.*

EMORY UNIVERSITY SCHOOL OF MEDICINE

FACULTY POSITIONS IN MOLECULAR GENETICS

Emory University School of Medicine is establishing a **DEPARTMENT OF HUMAN GENETICS** and is recruiting three outstanding individuals to help develop what is envisioned to be a leading center in molecular mammalian genetics. The department will occupy space in the new Rollins Research Center, a $40-million biomedical research facility ready for occupancy in December, 1989. A doctoral program in genetics is already in place and is nationally competitive in successfully recruiting outstanding students.

These positions may be filled at the Assistant to Associate Professor level and are tenure-track appointments. Each position will include a competitive salary, start-up equipment and guaranteed supply and technical/postdoctoral support for three years. Outstanding candidates with comprehensive training and research experience in molecular genetics, preferably in mammalian systems, are invited to apply. Send curriculum vitae, a brief research description and request three letters of recommendation **to: DR. STEPHEN T. WARREN, CHAIR, GENETICS SEARCH COMMITTEE, EMORY UNIVERSITY SCHOOL OF MEDICINE, ATLANTA, GA 30322.** Applications will be reviewed as received until January 30, 1990 or until all positions are filled. *Emory University is an Affirmative Action/Equal Opportunity Employer. Women and members of minority groups are encouraged to apply.* (NW4429)A

THE ROYAL VETERINARY COLLEGE
University of London
Department of Veterinary Basic Sciences

LECTURER IN VETERINARY PHARMACOLOGY

Applications are invited for the above post. The Department offers an elective in Clinical Pharmacology to final year students at its Hawkshead campus as well as giving the core course in Basic Pharmacology at Camden Town. Candidates should preferably have a veterinary degree and a postgraduate qualification in a discipline related to pharmacology Appointees will be expected to pursue their own line of research.

Persons interested in applying are asked to contact Professor David Lodge (01-387 2898) or Professor Peter Lees (0707-55846) for further information.

SALARY SCALE: Appointment will be on the Grade A or Grade B scale for lecturers of £12,108-£17,022 or £17,664-£22,119 per annum including London Allowance. In assessing the starting salary, consideration will be given to qualifications, age and experience.

Universities Superannuation Scheme.

REMOVAL EXPENSES up to £1,710 may be reimbursed in approved circumstances.

APPLICATION FORM from the **Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU ('phone: 01-387 2898).**

CLOSING DATE FOR APPLICATIONS: 15 NOVEMBER 1989 (1900)A

UNIVERSITY OF BRISTOL
Comparative Orthopaedic Research Unit
Department of Anatomy

Post-doctoral research assistant required to join large multidisciplinary team for a project sponsored by the Department of Health and an Orthopaedic Company on the development of knee ligament prostheses.

A medical, veterinary or engineering qualification would be an advantage. Salary range £10,458 to £16,665.

For further details telephone Bristol 303136 (ansaphone after 5.00 p.m.) or write to the Personnel Office, Senate House Bristol BS8 1TH.

Please quote reference A780.

Closing date Friday, 10th November, 1989. (1871)A

National Institute of Genetics
DNA Data Bank of Japan

*Assistant Professor

One post is available for a researcher whose training is in biology, biophysics, computer science, mathematics or another natural science, and who is interested in building and maintaining a DNA database, as well as sequence and structural analysis of DNA and proteins in approaches of biophysics, molecular evolution and computer science. The successful applicant is expected to be a good collaborator with Dr. Sanzo Miyazawa, who is the manager of the DNA Data Bank of Japan and other staffs.

Qualification: M.Sc. or Ph.D. is desirable. Basic knowledge of computer science and experience of using UNIX systems are required.

Duration: An appointment is for an initial three-year period as a governmental employee and may be extended.

Appointment: After Jan. 1, 1990.

Location: National Institute of Genetics, Mishima, Shizuoka 411, Japan.

The National Institute of Genetics is a governmental organization in Japan. The DNA Data Bank of Japan is collecting DNA data and building and maintaining a DNA database in collaboration with GenBank and the EMBL Data Library. The available computer system consists of Sun workstations, an Iris Graphic workstation, a FACOM M380Q/UTS(Unix), and a Micro VAX-II/VMS.

Applications, together with a curriculum vitae, a publication list, copies of some publications, a research history, research interests, the names and addresses of two persons for recommendation, should be sent to **National Institute of Genetics, Mishima, Shizuoka 411, Japan,** before December 31, 1989.

For details, please contact with Dr. Sanzo Miyazawa. His electronic mail address is smiyazaw%ddbj.nig.ac.jp@relay.cs. net, fax number is +81 559 75 6040: phone number is +81 559 75 0771 ext 649.

*Previously advertised incorrectly as Associate Professor — issue: 28/9/89, pg. 3. (W6617)A

ASSISTANT/ASSOCIATE PROFESSOR
ANATOMY AND CELL BIOLOGY

The Department of Anatomy and Cell Biology, State University of New York, Health Science Center, Syracuse, invites applications for a tenure track position at the Assistant or Associate Professorial level. Applicants should have a Ph.D. or M.D. degree and a minimum of two years of post-doctoral research experience. The department, is seeking an individual with a strong record of scientific achievement and capable of attracting extramural funding. Teaching opportunities will exist in medical and/or graduate courses. Although the specific area of research is not as important as excellence, preference will be given to candidates using modern approaches in cellular and molecular biology. The position provides a very competitive salary as well as generous set-up funds.

Individuals interested in being considered for this position should send a copy of their Curriculum Vitae, recent reprints, and the names of three references by March 15, 1990 to: Dr. Larry F. Lemanski, Professor and Chairman, Department of Anatomy and Cell Biology, State University of New York, Health Science Center at Syracuse, 750 E. Adams Street, Syracuse, New York 13210.

The State University of New York, Syracuse, is an Equal Opportunity/ Affirmative Action Employer. (NW4424)A

THE DEPARTMENT OF NEUROSCIENCES, UNIVERSITY OF CALIFORNIA, SAN DIEGO

is seeking qualified applicants for a position as **Assistant Research Neuroscientist.** The successful candidate will have experience with molecular biology techniques. Ability to work in a group or team setting necessary. M.D. or Ph.D. required with at least three years postdoctoral experience. Applications received on or before November 15, 1989 will be considered. Salary will be commensurate with candidate's experience and University policy. Send curriculum vitae, names and addresses of five references to: **Dr. Fred H. Gage, Department of Neurosciences, M-024, University of California, San Diego, La Jolla, CA 92093.** The University of California is an Equal Opportunity/Affirmative Action Employer. (NW4418)A

THE HEBREW UNIVERSITY OF JERUSALEM
FACULTY OF AGRICULTURE

A Position in Physiology of Agricultural Plants Under Stress Conditions

A tenure-track position is available in the Hebrew University of Jerusalem, Faculty of Agriculture, Department of Agricultural Botany, Rehovot, ISRAEL, for a **LECTURER**, with Ph.D. degree and after post-doctoral training. The candidate should have a strong background in plant sciences and genetics and affinity towards agriculture, as well as experience in molecular biology techniques.

The candidate's teaching responsibilities will include courses in plant physiology as well as participation in teaching other courses related to his research areas. All courses will be conducted in Hebrew.

The candidate will be expected to develop an original research program in the physiology of agricultural plants under stress conditions emphasizing the molecular level of gene expression. He/she will be expected to develop research contacts in Israel and abroad, and submit research proposals and supervise students at the graduate level.

The position will be available on October 1, 1990. Candidates should apply before January 1, 1990 to **Prof. E. Zamski, Head, Department of Agricultural Botany, Faculty of Agriculture, P.O. Box 12, Rehovot 76100, Israel.** Letters of recommendation from three prominent scientists are required and should be sent directly to the above address. (1898)A

UNIVERSITY OF UTAH
Department of Biochemistry

Tenure track positions are available for autumn, 1990 in the area of physical biochemistry, including determination of the structure of macromolecules, investigation of their mechanism of action, and measurement of energetic contributions to these properties. Individuals expert in NMR spectroscopy are particularly encouraged to apply. Preference will be given to applicants at the level of Assistant Professor, but candidates at more senior ranks may also be considered. Teaching responsibilities are largely to graduate and medical students. Applicants should hold a doctoral degree, have postdoctoral experience and demonstrable research ability. Interested individuals should submit curriculum vitae, a statement of research background and interests, and three letters of recommendation to: **Faculty Search Committee, Department of Biochemistry, University of Utah School of Medicine, Salt Lake City, Utah 84132** Deadline for applications is December 15, 1989; late applications may be considered if openings are still available. Equal opportunity, affirmative action employer. (NW4419)A

UNITED MEDICAL AND DENTAL SCHOOLS
Division of Anatomy, Guy's Campus
LECTURESHIP IN MOLECULAR NEUROBIOLOGY

Applicants for this post should have experience in molecular biological techniques and an interest in neurobiology. The lecturer will be expected to pursue independent research and contribute to undergraduate teaching. The appointment will be for 5 years in the first instance. Salary on University non-clinical Lecturer Scale A. £10,458–£15,372; Scale B; £16,014–£20,469 plus £1,650 London Weighting Allowance.

To discuss the post informally contact Professor M Berry (01-955 4360) or Dr Andrew Lumsden (01-955 4413) For further details, phone 01–928 9292 ext. 3341. Applications in the form of full curriculum vitae (6 copies) should be sent to the **Personnel Officer, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH** quoting reference G/ANA/419 by 14 November 1989. (1888)A

INSTITUTE OF OPHTHALMOLOGY
(University of London)
Judd Street, London, WC1H 9QS
DEPARTMENT OF VISUAL SCIENCE
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the post of Postdoctoral Research Assistant (Grade 1A) to work on a three-year project funded by the MRC entitled *Transmitters of Visual and Somatosensory Afferents to the Mammalian Superior Colliculus.* Experience of neurophysiological and/or neuro-pharmacological techniques (especially in relation to amino acid transmitters or sensory systems) would be an advantage, although not necessarily essential Salary in the range £12,381 - £13,527 plus £1,650 London Allowance Applications, including cv should be sent to Dr. T.E. Salt at the above address. Tel. (01)387 9621 ext 231. (1859)A

POSTDOCTORAL MOLECULAR BIOPHYSICS IN PARIS

A one-year renewable post will be available in the fall of 1990 for theoretical research into the internal dynamics of proteins. Emphasis on calculation of spectra from molecular dynamics computer simulations. Good physics/physical chemistry background helpful.

Competitive salary.

Applications, including CV and names and addresses of 3 referees should be sent to:

Dr. J. SMITH, Molecular Modelling Lab.,
Service de Biophysique,
Département de Biologie,
Institut de Recherche Fondamentale,
C.E.A., C.E.N., SACLAY,
91191 GIF-SUR-YVETTE CEDEX, FRANCE
(W6623)A

THE UNIVERSITY OF WESTERN AUSTRALIA
PERTH

Agreement has been reached between Murdoch University and The University of Western Australia to seek amalgamation of the two institutions, subject to legislative approval, by January 1990.

RESEARCH ASSOCIATE IN PHYSICS (TWO POSITIONS) (REF: A85/89)

The Gravity Research Group has two research associate positions available renewable for up to three years. One position involves continuing research into the detection of gravitational radiation, the other the development of ultra high stability time and frequency standards. We are seeking bright experimental physicists with experience in one or more of the following areas: microwaves; cryogenics, rf and digital instrumentation; superconductivity. For further information contact Dr D G Blair, Physics Department (09) 380 2736.

Salary range A$27,139-A$30,882 p.a. Conditions of appointment will be specified in any offer of appointment which may be made as a result of this advertisement.

Written applications quoting reference number, telephone number, date of birth, qualifications and experience, and the names, addresses and fax/telephone numbers of three referees should reach the Director, Personnel Services, The University of Western Australia, Nedlands 6009, Australia by 30 November 1989.

Equal Employment Opportunity is University Policy.
(W6613)A

SENIOR FACULTY POSITIO
Molecu Biolog

Syracuse University has initiated program of growth and developme of a strong unit in molecular biolo within the Department of Biolog Several stages of recruitment that w encompass both junior and senic faculty positions are planned and ne facilities, including 23,000 sq. ft. research space, are under develo ment. Applications for a senior positic are invited at this time. Applican must have a vigorous research pr gram supported by extramural fundir and a strong record of accomplis ments. Areas of specialization with molecular biology are unrestricte The successful candidate will hav substantial time available f research, but participation in th instruction of undergraduate an graduate students is expected. Curr culum vitae, including a statement c career and research goals, inform tion on research support, and th references should be sent by Janua 1, 1990 to: **Dr. J.K. Bryan, Departme of Biology, SYRACUSE UNIVERSIT 130 College Place, Syracuse, N 13244–1220.** *AA/EOE.* (NW4426)A

POSTDOCTORAL POSITIO

The Dana-Farber Cancer Institut is seeking to fill one researc position at the postdoctoral leve to study the ability of T-ce products to regulate the immun response in collaboration wit other laboratory investigators. joint appointment will be held i an appropriate department Harvard Medical School. Ser C.V. and names of three refe ences to **Dr. Harvey Canto Laboratory of Immunopathology Dana-Farber Cancer Institute, 4 Binney Street, Boston, MA 02115** An Equal Opportunity Employer (NW4423)A

LEP
SCIENTIFIC

BIOTECHNOLOGY PRODUCT MANAGER

LEP Scientific are now established in the field of Molecular Biotechnology, and as a result, a new Biotechnology Product Division is being formed within the company's highly successful sales organisation. This Division will deal with an expanding new range of products aimed at all major Laboratories in the UK, and Overseas.

An experienced, motivated Salesperson or Specialist with in-depth knowledge of HPLC, DNA Sequencing, and Electrophoresis techniques would be an ideal applicant.

The position is based in Milton Keynes and relocation expenses will be considered for the right candidate.

The position will demand dedication and continuous effort to launch this new range of products, therefore a substantial remuneration package will be paid to the successful applicant.

Please contact Mark Burnard on 0908 670066, or apply in writing to him at Southern Recruitment, 546 and 542 Elder Gate, Elder House, Central Milton Keynes, MK9 1LR.

SEARCH **southern recruitment**

(1891)A

The newly formed Basic Science Department of Microbiology at the University of Texas Medical School, at Houston, invites applications for both tenure track and tenured faculty positions at the level of

Assistant, Associated or Full Professor.

The initial areas of recruitment interest are in: Procaryotic Microbial Physiology, Microbial Genetics and Molecular Microbiology. Candidates must have the Ph.D. and/or the M.D. degree. Postdoctoral Research experience is essential for consideration of a prospective assistant professor. Applicants for associate or full professorships must have demonstrated high quality research performance. Successful applicants will be expected to teach medical students, graduate students and develop and/or maintain a high level, high visibility research program, competitive at the national level. Please send a curriculum vitae and a statement of teaching and research interests as well as the names of four referees to: **Dr. Samuel Kaplan, Department of Microbiology, The University of Texas, Medical School, at Houston, P.O. Box 20708, Houston, Texas 77225.** *The University of Texas Health Science Center is an Equal Opportunity Employer. Woman and minorities are encouraged to apply.* (NW4384)A

RESEARCH SCIENTIST

To undertake a vaccine development program which has as its initial objective the development of a subunit vaccine for human parainfluenza viruses; to utilize recombinant DNA approaches for expression of the viral glycoproteins and utilize affinity chromatography for purification of these molecules; with the resulting preparations being evaluated for efficacy in experimental animals and human volunteers. Experience in molecular biological work including cloning, sequencing and expression of viral genome; immunization, virus challenge and virus titration in animals. Sufficient knowledge of biology and biochemistry of viral glycoproteins; growth and purification of viruses; expression of viral proteins using recombinant DNA techniques; production & characterization of monoclonal antibodies; SDS-polyacrylamide gel electrophoresis. Salary is $22,000 per year. Resume to **George Johns, Alabama State Employment Service, P.O. Box 12046, Birmingham, AL 35202-2046. Job order # ALO585485.**

MAF

IMMUNOASSAY DEVELOPMENT IMMUNOCHEMIST/ORGANIC CHEMIST/BIOCHEMIST

MYCOTOXIC DISEASES GROUP RUAKURA AGRICULTUAL CENTRE MAF HAMILTON, NEW ZEALAND VACANOY-NO, MTN 89/54

The Mycotoxic Diseases Group of the Ministry of Agriculture and Fisheries has a vacancy for a researcher to lead a small team of technicians developing immunoanalytical procedures to detect and determine mytotoxins in feedstuffs, animal tissues and body fluids. Work will involve the synthesis of immunogens, production of polyclonal and monoclonal antibodies and the optimisation of the extraction and analysis of targeted analytes

The appointee will have experience and expertise in one or more of the following:

- ★ organic chemistry - modification and derivatisation of organic molecules and the synthesis of immunogens
- ★ antibody production and characterisation - experience with monoclonal techniques would be advantageous
- ★ immunoassay development (RIA, ELISA, EMIT etc.) - exprience in developing and validating assays for small analytes such as drugs, hormones or mycotoxins preferred.

Minimum qualifications are a PhD or an Honours degree with 3–5 years relevant experience. Preference will be given to applicants with Post-Doctoral or equivalent experience.

The appointment will be for an initial 3 year term with renewal for a further 1–3 years by mutual consent.

Ruakura is located in the university city of Hamilton (popn 100,000) which has a surrounding pastoral agricultural community. City community services, including education and cultural activities are excellent, and access to outdoor recreational opportunities (sports, fishing, skiing etc.) are superb.

Further information can be obtained from Dr Neale Towers, Ruakura Agricultural Centre, Private Bag, Hamilton, New Zealand. Telephone 64–71–62839, FAX 64–71–385658.

Applications quoting vacancy number MTN 89/54 including a curriculum vitae and the names of two referees should be sent to: **Management Support Officer, Animal Research Group, MAFTech, Ruakura Agricultural Centre, Private Bag, Hamilton.** Applications for vacancy close on 15 November 1989. Middlesex

mrc

POST DOCTORAL SCIENTIST

MOLECULAR GENETICS OF THE MOUSE X CHROMOSOME

Applications are invited for a 3 year post-doctoral appointment to join an established group working on the molecular genetics of the mouse X chromosome. The project will initially involve the construction of genomic libraries in Yeast Artificial Chromosome vectors (YAC's). Subsequent work will involve the use of this resource to isolate genes associated with a number of X-linked loci, including the X-inactivation centre. This project will complement ongoing research on the genetic and physical mapping of CpG island clones onto the X chromosome. The group also has established facilities for making transgenic mice by oocyte injection and embryonic stem (ES) cell manipulation.

Experience in the methods of Molecular Genetics/Molecular Biology is desirable.

Informal enquiries to Dr S Rastan or Dr N Brockdorff, 01-869 3266.

Salary will be at an appropriate point on the scale for non-clinical university academic staff Application forms may be obtained from the Personnel Department, 01-869 3431 quoting ref. 102/1/3912. Closing date for applications 10th November 1989

The Medical Research Council is an Equal Opportunity Employer. (1889)A

POSTDOCTORAL FELLOW: MOLECULAR BIOLOGY OF NEURAL INDUCTION

Excellent prospects for beginning a research project aimed at resolving one of the core problems of neurobiology, using molecular biological and immunological methods. Expertise in molecular biology essential. **Write: Marcus Jacobson, Anatomy Department, University of Utah Medical School, Salt Lake City, UT 84132. Telephone: 801-581 6720.** The University of Utah is an Equal Opportunity Employer. (NW4400)A

FELLOWSHIPS

POSTDOCTORAL FELLOWSHIPS WOODS HOLE OCEANOGRAPHIC INSTITUTION

Ocean Science and Engineering

Applications are invited from new or recent doctorates in science or engineering with interests in physical oceanography, meteorology, marine chemistry, marine geology and geophysics, biological oceanography, or oceanographic engineering. Recipients of awards are selected on a competitive basis, with primary emphasis placed on a research promise

Marine Policy and Ocean Management

Research fellowships are offered to individuals in the social sciences, law, the humanities, or natural sciences to apply their training to problems or issues that involve the use of the oceans. Presently research follows thematic areas such as Marine Science and Public Policy; Ocean Jurisdictions, Law of the Sea, and International Relations; Development and Management of Ocean Resources; and Areawide Planning and Management. Emphasis is placed on the economics of ocean space and on the role of science in governmental and industrial decision making. Topics of special current interest include marine biological diversity, the quality of marine habitats and marine reserves, and the impacts of sea-level change. Other research interests are also appropriate.

Fellowships are rewarded for one year with a stipend of $30,500 plus group health insurance and a modest research budget. Recipients are encouraged to pursue their own research interests independently or in association with resident staff. Completed applications must be received by January 15, 1990 for 1990-91 awards. Awards will be announced in March. Write for application forms to: Dean of Graduate Studies, P.O. Box N, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543

Equal Opportunity/Affirmative Action Institution

Post Doctoral Research Fellow

The Imperial Cancer Research Fund is the largest independent cancer research institute in Britain with wide ranging interests in fundamental, applied and clinical research We now have an excellent opportunity for a post doctoral research fellow to join our Human Tumour Immunology Unit

Working in the area of T-cell biology within a group of five studying the interactions which occur in the thymus between stromal cells and T-cell precursors for 3 years initially You will also be encouraged to pursue independent research projects and collaborate with members of the Human Tumour Immunology Group, the Tumour Immunology Unit, as well as our main laboratories at Lincoln's Inn Fields, WC2

Familiarity with standard tissue culture and molecular biology approaches essential Post doctoral research experience in a related area is desirable but not essential For further details contact Dr Amanda Fisher on 01-380 9325

£14,800-£18,400

Applications should be made by sending full cv plus names and addresses of three referees to the Recruitment Officer, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX quoting the reference 258/R. Closing date for applications: 10th November 1989.

Smoking is actively discouraged.

Imperial Cancer Research Fund

SITS. VAC. cont.

Universität Heidelberg

The Zentfum fur Molekulare Biologie (ZMBH) at the University of Heidelberg invites applications for a

full professorship in molecular biology (C4)

as part of the Baden-Wurttemberg Promotion Programme for young scientists

The research program of the successful candidate is expected to contribute to the ZMBH's research activities which focus on

— regulation of gene activity and differentiation.
— molecular neurobiology.
— molecular mechanisms of pathogenicity.

Collaboration with the research groups of the ZMBH as well as participation in the research programs sponsored by the Deutsche Forschungsgemeinschaft "Molekulare Mechanismen der Genexpression und Differenzierung" (SFB 229) or "Molekularbiologie neuraler Mechanismen und Interaktionen" (SFB 317) will be expected. The holder of the position will furthermore participate in the department's teaching program

The ZMBH presently houses 16 independent research groups and offers excellent central services which include DNA- and peptide synthesis, protein microsequenzing FACS animal facilities and centralized administration.

The applicant should, at the time of nomination, be younger than 45 years of age.

Applications should reach the Direktor of the ZMBH Prof H Bujard. Im Neuenheimer Feld 282, D-6900 Heidelberg, FRG, before Dec. 15, 1989 (W6630)A

UNIVERSITY OF GLASGOW
Departments of Botany and Biochemistry
POSTDOCTORAL FELLOWSHIPS

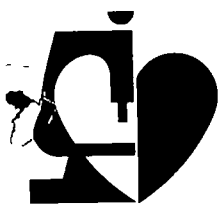
Applications are invited for *three* Research Council-funded postdoctoral fellowships (1A scale, starting salary up to £11,088) on the following topics.

1. Structural and Genetic Studies on the Mitochondrial Phosphate Transporter (funded under the SERC-Membrane Initiative jointly to Dr. J. G. Lindsay and Professor R. J Cogdell).
2. Pyruvate Dehydrogenase Complexes of Plant Mitochondria and Chloroplasts (AFRC grant jointly to Dr. J. G. Lindsay and Professor R J. Cogdell)
3. Regualation of the Expression of Light-Harvesting Complexes in *Rps. acidophila* (SERC grant to Professor R. J. Cogdell).

Suitably qualified applicants preferably with appropriate experience in molecular biological, immunological and protein-chemical techniques should send a detailed C.V. to **Professor R. J. Cogdell, Department of Botany (Tel No. 041-339 8855 x 4232)** or **Dr. J. G. Lindsay, Department of Biochemistry, University of Glasgow (Tel. No. 041-339 8855 x 4720),** from whom further details may be obtained. The positions are tenable for a period of up to three years. The deadline for applications is 17th November, 1989. (1865)E

IMPERIAL COLLEGE (UNIVERSITY OF LONDON)
THREE POST-DOCTORAL FELLOWSHIPS FOR RESEARCH INTO BIOMOLECULAR STRUCTURE AND FUNCTION

Three positions are available for postdoctoral research fellows to join a multidisciplinary team working on structure/function of biopolymers. The laboratory has unique facilities including two high field fast atom bombardment mass spectrometers, gas phase sequencers and ancillary equipment for protein and carbohydrate analysis. A state-of-the-art high mass array detector mass spectrometer will be installed next year The work includes studies of parasite antigens, glycoconjugates and post-ribosomal modification of proteins. Candidates should preferably have experience in protein or carbohydrate chemistry. Mass spectrometric experience is not essential because training will be given. Salary will be in the range RAIA scale £10,458–£16,665, plus £1,650 London Allowance. Applications with full C.V. and the names and addresses of two referees should be sent to **Professor H R Morris, Department of Biochemistry, Imperial College, London SW7 2AZ.** (1887)E



LEICESTER UNIVERSITY
Geology Department
3 Year PhD Studentship
funded by UKAEA Winfrith

We are looking for a geoscientist with an interest in sedimentary/petroleum geology to work on a major new project investigating the characterisation of oilfield rocks. The study forms part of a European initiative and will involve working as part of a team involved with the chemical and physical properties of rocks in an exciting collaborative venture with substantial industrial connections. The work will be laboratory based, but represents a considerable challenge to a rapidly developing field.

Enquiries and applications, including the names of two referees, should be made to: **Dr. Mike Lovell, Geology Department, University of Leicester, Leicester, LE1 7RH** (tel: 0533-523798). The project is due to start 1st January 1990 and consequently applications should be submitted by November 1st. (1862)F

PATERSON INSTITUTE FOR CANCER RESEARCH
Christie Hospital and Holt Radium Institute
Manchester, M20 9BX
POSTGRADUATE RESEARCH STUDENTSHIP

A PhD Studentship (grant £4732 pa) is available for 3 years to study the modification of the radiation response of the normal and malignant pituitary gland, using modulators of cell turnovers and hormone secretion, with a view to improvements in particular radiotherapeutic treatments. The project is multi-disciplinary between departments in the Paterson Institute, the Christie Hospital and the University, and will be supervised by Drs J H Hendry, I D Morris, J Davies and C G Beardwell. Applicants should have a first or upper second class honours degree in an appropriate subject. A detailed CV including the names of two academic referees should be sent to Dr J H Hendry, Department of Radiobiology, Paterson Institute for Cancer Research, Christie Hospital and Holt Radium Institute, Manchester, M20 9BX, UK, to arrive no later than 9 November 1989. (1892)F

RESEARCH STUDENTSHIPS
in Molecular Biology, Cell Biology, and Biochemistry of Atherosclerosis

A number of research studentships will be available for graduates of science and medical faculties concerning the molecular mechanisms of endocytosis, cell biology of macrophages and biochemistry of free radicals.

Please apply with c.v., and contact FAX number to:

Prof. Roger Dean,
The Heart Research Institute
145 Missenden Road,
Camperdown NSW 2050

FAX: +61 2 550 3302

Sydney, Australia

STUDENTSHIPS
continued on page 23

Merrell-Dow/Université Louis Pasteur Fellowship of the Académie des Sciences

A post-doctoral fellowship will be available at Université Louis Pasteur, Strasbourg, starting from the end of 1989 early 1990, for work on applications of Nuclear Magnetic Resonance to the determination of structure and dynamics of petides, proteins and DNA sequences involved in mutagenesis. Available spectrometer fields: 200, 300, 400 and 500 Mllz. Computational, modelling and graphic display capabilities. The research programme is developed in close collaboration with molecular biologists.

The successful candidate will preferentially have obtained very recently a Ph.D in Organic Chemistry, in Biochemistry or in Biophysics, if possible with some experience in high field NMR. His appointment will be for one year, exceptionally renewable, at the rate of 10,000 FFR/month. Health insurance and help for housing provided. No travel funds.

The Merrell-Dow Fellowship was funded to promote the international relations of Université Louis Pasteur, in particular with the USA. The beneficiary and his laboratory are completely free to define the problem chosen and to publish the results obtained.

Candidates are requested to send a detailed C.V. and the names of two referees to **"Prof. J.F. LEFEVRE, I.B.M.C., 15 rue René Descartes, 67084 Strasbourg Cedex, France"**, before December 1st. (W6605)E

UNIVERSITY OF GLASGOW
INSTITUTE OF GENETICS
POST DOCTORAL RESEARCH FELLOWSHIP
IN MOLECULAR NEUROBIOLOGY

Applications are invited for a post doctoral research fellow (1A scale) to join a group concerned with the molecular analysis of nervous system development. The project involves the characterisation of genes expressed in nervous tissue of *D melanogaster* and will be multidisciplinary, employing recombinant, cytological and genetic techniques. Experience in any of these areas will be an advantage.

The post is funded by the SERC and is available from 1st October, 1989, for 3 years. Starting salary will be commensurate with age and experience. Please send a Curriculum Vitae and names of 2 referees to **Dr. J. Davies, Institute of Genetics, Church Street, Glasgow G115JS** (Telephone: 041-339-8855). (1864)E

POSTDOCTORAL FELLOWSHIP:

A position is available immediately to study the regulation of phospholipid metabolism and its relationship to signal transduction and the cell cycle. Candidates with a Ph.D. degree should submit their curriculum vitae, reprints and names of three references to: **Dr. Charles O. Rock, St. Jude Children's Research Hospital, 332 N. Lauderdale, Memphis, TN 38101.** *An Equal Opportunity/Affirmative Action Employer.* (NW4407)E

Smithsonian Institution Fellowship Program

GRADUATE STUDENT, PRE-, POST-, and SENIOR POSTDOCTORAL FELLOWSHIPS

in American history and material culture, anthropology, biological sciences, earth sciences, history of art, history of science and technology. Tenable in residence at the Smithsonian and its research facilities. Stipends and tenures vary.

Deadline: January 15th annually.

Contact: **Smithsonian Institution, Office of Fellowships and Grants, 955 L'Enfant Plaza, Suite 7300, Desk N, Washington, D.C. 20560 (202) 287-3271.**

Awards are based on merit, without regard to race, color, religion, sex, national origin, age, or condition of handicap of applicant.

(NW4285)E

ARE YOU LOOKING FOR OPPORTUNITY IN RESEARCH?

Research Development Corporation of Japan (JRDC), established in 1961, is a government owned organization which operates under the Science and Technology Agency (STA).

The objective of JRDC is to effectively carry out the development of new technology, engage in the basic research deemed to contribute to the creation of new technology, and to disseminate the outcome of these developments and basic research.

In addition to these activities, JRDC is to undertake the promotion of the International Research Exchange Program, consisting of 1) The International Joint Research Program, 2) The STA Fellowship Program, 3) The Support Programs, and 4) The Research Information Program.

INTERNATIONAL JOINT RESEARCH PROGRAM

1. Purpose

This program shall work toward the following purposes through joint research supported by JRDC and foreign research organizations:

(1) Develop the seeds of innovative science and technology by integrating the advanced research activities of Japan and of other countries concerned; (2) Contribute internationally by fostering broad public dissemination of the knowledge gained from such research; and (3) Promote research exchange between Japan and other countries, thereby promoting science and technology.

2. Outline of the Program

Non-Japanese research organizations wishing to conduct joint research projects with JRDC shall carry out such research with JRDC within the following framework, and shall share, on an equitable basis, personnel and all expenses and costs necessary for the implementation of the research.

(1) Research fields and themes

Research themes are to be sought in basic research fields including new materials, life sciences and electronics. Themes should be directed toward creating new concepts that will become the seeds of innovative science and technology development. These research themes must be those for which consent is obtained from both JRDC and its counterpart.

(2) Framework for a Joint Research Project (Standard model for joint research)

① Term: 5 years (Flexible: 3 to 7 years)

② Budget: ¥ 2 to ¥ 3 billion (approx U.S.$14–21 mil.) [Each side bears ¥ 1 to 1.5 billion]

③ Site:

A research site shall be established at a suitable university or a research institute.

④ Researchers:

Both JRDC and its foreign counterpart concerned may select their respective researchers from academia, industry and government.

i) Research directors: 2 (one from each side)

ii) Researchers: 15 to 20 in total for both countries.

⑤ Patent rights:

The patent rights resulting from the joint research should be jointly owned on an equitable basis.

STA FELLOWSHIP PROGRAM

1. Purpose

The purpose of this program is to promote the international exchange of researchers by providing fellowships to foreign researchers in the science and technology fields (excluding those concerned exclusively with the humanities).

2. Outline of the Program

Fellowship awardees fall into two categories: (1) those recommended by their own governments and (2) those recommended by Japanese host institutes.

(1) Numbers of awardees: 130 for FY 1989 (100 for FY 1988).

(2) Qualifications:

① Possession of a doctoral degree in a scientific or engineering field, or an equivalent qualification.

② Age under 35, in principle.

③ Having sufficient language ability to be able to pursue research in Japan. Japanese ability is preferable, but in most cases English ability is sufficient. With the host institute's agreement, other languages may also suffice.

3. Tenure and field of research:

Tenure is between 6 months and 2 years, to be decided through negotiation between the candidate and the host institute.

The field of research is also decided through negotiation between the candidate and the host institute. The results of research work produced during the tenure will be subject to the regulations of the host institute.

4. Fellowship awards:

The following items will be provided to the Fellowship awardees as tax-free allowances.

① Round-trip airline ticket (economy class).

② Living allowance: ¥ 270,000 per month, (approx U.S.$2,000).

③ Family allowance: ¥ 50,000 per month (approx U.S.$370).

④ Housing: ¥ 100,000 maximum per month (approx. U.S.$740) may be paid as housing allowance; any shortfall is to be borne by the awardee.

⑤ Relocation allowance for moving from overseas to Japan: ¥ 200,000 (approx. U.S.$1,500).

⑥ Travel allowance (in Japan for business trips regarding research activities): ¥ 100,000 maximum per year (approx. U.S.$740).

5. Host Institutes

Host institutes comprise national laboratories (excluding universities and laboratories affiliated with universities), public (semi-government) corporations, and non-profit organizations.

JRDC is to undertake the implementation of STA Fellowship Program: Japan International Science and Technology Exchange center (JISTEC) is responsible from the receipt of the application from candidates and liaising with them.

SUPPORT PROGRAMS

In order to help foreign researchers, who are engaging in research or exchanging information at Japanese research institutes, and their families to make a smooth transition to research and enjoy their everyday life, JRDC is to promote support programs such as assistance to find houses, supply of information on living in Japan, counselling for daily life and Japanese language lessons.

RESEARCH INFORMATION PROGRAM

For foreign research institutes and researchers who are seeking opportunities for research exchange with Japanese counterparts, information focused on Japanese research activities will be provided.

FROM CLONE TO CLINIC

An international meeting on the development of biotechnological products for use in humans

Amsterdam, the Netherlands

19-22 March 1990

The meeting will cover pharmaceutical, toxicological and clinical aspects of therapeutically active agents obtained via rDNA techniques and hybridoma technology. It will particularly emphasize steps after obtaining the clone.

Topics include: cell culture techniques, purification, processing, formulation, stability, standardization, quality control, pharmacology, toxicology, clinical evaluation and regulatory affairs.

Organizing Committee:
D.J.A. Crommelin, chairman
F.E. André, W.J.C. Melgert, H. Schellekens

Programme Committee:
A. Billiau, D.D. Breimer, L. Gauci, E.H. Houwink, R.E. Jones, H. Koprowsky, H.R. Maurer, K. Nomoto, W. Sadee, G.C. Schild.

SYMPOSIUM ON HUMAN GENOME RESEARCH: STRATEGIES AND PRIORITIES

29-31 January 1990

UNESCO Headquarters, 7 Place de Fontenoy, 75007 Paris, France

This Symposium, organized by G. Bernardi (Paris), F. Gros (Paris), V. Sgaramella (Pavia), M. Singer (Washington), and N. Zinder (New York) is co-sponsored by the Committee on Genetic Experimenation (COGENE) of the International Council of Scientific Unions (ICSU), the European Economic Community (EEC), the Federation of European Biochemical Societies (FEBS), and the United Nations Educational, Scientific and Cultural Organization (UNESCO).

The aim of the Symposium is to review the present status of genome research and to discuss its future developments especially in Europe, as well as the participation of developing countries.

The program will comprise the following Sessions:

1. **The genomes of bacteria, yeast, plants and invertebrates.** Chairman, F. Jacob (Paris); S. D. Ehrlich (Jouy en Josas), H. Feldman (Munich), F. Kafatos (Harvard, Heraklion), J. Schell (Cologne).
2. **The human genome: organization, genetic and physical mapping.** Chairman: J. Watson (Cold Spring Harbor); G. Bernardi (Paris), A. Bird* (Vienna), W. R. A. Brown* (Oxford), K. Gardiner (Denver), D. Schlessinger (St. Louis), M. Singer (Washington), R. White* (Salt Lake City).
3. **The human genome: developments in experimental approaches.** Chairman: P. Berg (Stanford); W. Ansorge (Heidelberg), J. Celis (Aarhus), H. Lehrach (London), A. Mirzabekov (Moscow), M. Olson* (St. Louis), V. Sgaramella (Pavia), M. van der Ploegh (Leiden).
4. **The human genome: genetic diseases.** Chairman: J. Dausset (Paris); T. Caskey* (Houston), D. Cohen (Paris), K. Davies* (Oxford), B. Jordan (Marseille), J. L. Mandel (Strasbourg), J. Weissenbach (Paris), H. Zachau (Munich).
5. **Genome projects under way.** Chairman: W. Gilbert (Cambridge); A. A. Bayev (Moscow), C. Cantor (New York), R. Dulbecco (La Jolla), P. Fasella (Bruxelles), K. Matsubara* (Japan), L. Philipson (Heidelberg), G. Tocchini-Valentini (Rome), N. Zinder (New York).
6. **The participation of developing Countries and of international organizations.** Chairman: R. Dulbecco (La Jolla); J. Allende* (Santiago), K. Tewari* (New Delhi), J. Tooze (HUGO).
7. **Genome Research: a critical assessment of strategies.** Chairman. W. Arber (Basel); E. Barnard (London), R. Weinberg (MIT) and others.
8. **Genome Research: ethical and legal problems.** Chairman: J. Kendrew (Cambridge); B. Müller-Hill (Cologne), P. Starlinger (Cologne) and others.

Invited participants include: M. Ashburner* (Cambridge), F. Ben Hamida (Tunis), A. Bernardi (Gif-sur- Yvette), U. Bertazzoni (Bruxelles), A. Boué (Paris), F. Chapeville (Paris). O. Ciferri (Pavia), J. M. Claverie (Paris), G. Cohen (Paris), S. Cohen (Stanford), C. Coutelle (Berlin), P. Day (New Brunswick), K. Dellagi (Tunis), J. P. Ebel (Strasbourg), M. Fellous (Paris), J. Frézal (Paris), F. Galibert (Paris), G. Georgiev (Moscow), A. Goffeau (Louvain), S. Grisolia (Valencia), M. Grunberg-Manago (Paris), A. Kahn (Paris), J. C. Kaplan (Paris), E. Katchalski-Katzir (Rehovoth), R. Keynes (Cambridge), G. Macaya (Costarica), J. Marton-Lefèvre (Paris), W. Mommaerts (Heidelberg), O. O. Ole-MoiYoi (Nairobi), S. Panyim (Bangkok), C. Rolz (Guatemala), J. Rosa (Paris), A. Rynditch (Kiev), G. Salvatore (Naples), M. Siniscalco (Alghero), A. M. Skalka (Philadelphia), K. Skryabin (Moscow), R. G. Tsanev (Sofia), P. Venetianer* (Szeged). (Asterisks indicate participations that have not yet been confirmed).

Applications for participating in the Symposium (including a brief curriculum vitae and a list of recent publications) should be sent to **G. Bernardi, Laboratoire de Génétique Moléculaire, Institut Jacques Monod, 2 Place Jussieu, 75005 Paris, France.** The registration fee will be 300 US Dollars. Participants below the age of 31 will pay a 150 US Dollars fee and may apply for FEBS Fellowships covering both travel and living expenses.

(W6626)M

Glaxo Research Scholarships

For the year 1990/91 Glaxo Group Research Limited will award six special Research Scholarships for study in British Universities leading to the degree of PhD.

The students holding these awards will receive a stipend of £6,250 (£7,200 for students at a London Institution) per annum for a period of three years. This amount will be adjusted in the second and third years to take account of increases in the cost of living. Included in the Scholarship will be an amount to meet the University and College fees and the Department sponsoring the student will receive a contribution to the project costs Recipients of these scholarships will be required to spend not less than three months during the period of the award working in the laboratories of Glaxo Group Research. During this period they will receive remuneration and living expenses in addition to the stipend

These scholarships will be open to competition, and potential students should apply through their prospective University Supervisor. Each candidate will be required to submit an essay of about 3000 words on their proposed subject of study. These will be judged by senior members of Glaxo Group Research's scientific staff.

Applications, which should include brief details of the student and the proposed project, should be submitted through University Supervisors to Glaxo Group Research by 9th December 1989; essays from students should be submitted by 10th January 1990. Please address all correspondence regarding the scheme to the Director of External Scientific Affairs, Glaxo Group Research Limited, Greenford Road, Greenford, Middlesex UB6 OHE, from whom further details are available if required.

Glaxo Group Research

WORKSHOPS

An EMBO International Workshop on the MOLECULAR AND DEVELOPMENT BIOLOGY OF DROSOPHILA will be held at Kolymbari, Crete (Greece) April 29–May 7, 1990

The workshop will be co-sponsored by the University of Crete and the Molecular Biology and Biotechnology Institute of the Research Center of Crete

As has been the case in previous years, the objective of the workshop is to discuss selected topics in gene organization and expression, early development, pattern formation, developmental neurobiology and evolution. Approximately 70 participants will be selected by vote by the organizing committee from applicants The participants are expected to contribute to the subject coverage. Applications should include a short summary of research interests and a brief C.V. if such information is thought to be important in facilitating the selection process

THE DEADLINE FOR APPLICATIONS IS DECEMBER 1 PLEASE NOTE THAT FOR LOGISTICAL PURPOSES WE NEED TO ADHERE STRICTLY TO THIS DEADLINE. PLEASE SEND APPLICATIONS TO:

Dr. S Artavanis-Tsakonas
CRETE WORKSHOP
DEPARTMENT OF BIOLOGY
Yale University
P.O. Box 6666
New Haven, CT 06511–8112
U.S A.

It is expeted that a registration fee of $300 will be remitted upon acceptance Local expenses in Crete will be covered. Participants are expected to finance their travel to Crete. However, a small number of grants in aid for partial travel support may become available. Preference will be given to junior investigators.

The Organizing Committee M Akam (University of Cambridge), S Artavanis-Tsakonas (Yale University), M Ashburner (University of Cambridge), A Bucheton (CNRS-Gifsur-Yvette), A. Carpenter (University of California, San Diego), A. Garcia-Bellido (Universidad Autonoma de Madrid), W. Gehring (Universitat Basel), W. Gelbart (Harvard University), D. Glover (Imperial College of Science and Technology), C. Goodman (University of California, Berkeley), D. Hogness (Stanford University School of Medicine), D. Ish-Horowicz (ICRF, University of Oxford), F. Kafatos (Crete and Harvard Universities), P Lawrence (University of Cambridge), K Louis (University of Crete), G. Morata (Universidad Autonoma de Madrid), J Nusslein-Volhard (Max Planck Institut), M. Pardue (Massachusetts Institute of Technology), G. Rubin (University of California, Berkeley), B. Shilo (Weizmann Institute), E. Wieschaus (Princeton University), H Jaeckle (University of Munich) (NW4422)V

STUDENTSHIPS continued

UNIVERSITY OF NOTTINGHAM
Cancer Research Campaign Laboratories

A Ph.D. Studentship

is available in the Cancer Research Campaign Laboratories to study growth regulation of gastrointestinal tumours by hormones and growth factors. Chemical or biological inhibitors of secretion or binding of these factors will be studied as potential new therapies for this common cancer.

Candidates must hold at least an upper second class degree. Further details may be obtained from **Dr. L. G. Durrant, Cancer Research Campaign Laboratories, University of Nottingham, University Park, Nottingham, NG7 2RD,** to whom applications including a curriculum vitae and names of two academic referees should be sent.

Closing date 30th November, 1989. (1866)F

There is no other journal in the world that reaches so many professional scientists in so many countries.

nature
INTERNATIONAL WEEKLY JOURNAL OF SCIENCE

Are you a science detective?

Do you spend hours searching the library shelves for clues to the whereabouts of this week's issue of Nature or waste time tracking down the last person on the circulation list?

Whether it's the latest developments in AIDS vaccines, maps of the sea bottom, debates on Darwinism or details on supernovae explosions that you're looking for, you need search no longer.

A personal subscription to Nature puts the most recent scientific developments in your hands only hours after the text goes to the printers.

Not only that, but you can read Nature at your leisure without fear of being chased by librarians or colleagues frantic for that one treasured copy.

You can even build up a permanent Nature reference library with its own Nature Index to make the information instantly accessible and ready to hand.

Stop the search now

Take out a personal subscription to Nature today at HALF PRICE.

STRATAGENE IN CAMBRIDGE

Stratagene proudly announces the opening of our new distribution and technical support center in Cambridge, England.

Stratagene, the company that has brought you Gigapack®, Lambda Zap®, and a full catalog of innovative reagents and equipment for the molecular biology laboratory is now pleased to offer you efficient delivery and technical support service.

Please contact Stratagene Ltd. or Northumbria Biologicals Ltd. for ordering information and to be placed on our mailing list to receive "Strategies" newsletter — filled with useful techniques for the laboratory and our newest product releases.

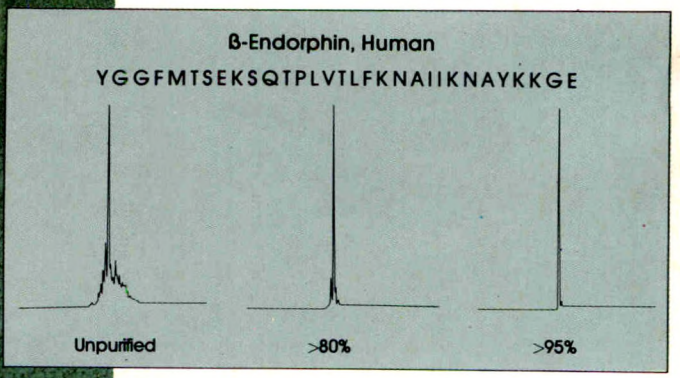
NEW MECHANISM FOR DEEP EARTHQUAKES



NEUROSCIENCE
product review

NOW Purified Peptides

MPS specializes in quality, custom peptide synthesis . . . so you don't have to!

In order to meet the differing needs of individual researchers, we are now offering three grades of peptides: unpurified, >80% purity and >95% purity. Additionally, for those using peptides to raise anti-peptide antibodies, MPS also provides a peptide carrier conjugation service. Call us with your questions or if you would like a complete price list.

COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

	Unpurified	Guaranteed Purity Level >80%	>95%
Quantity	50-100 mg	30-50 mg	20-30 mg
10 mer	$400	$700	$1000
15 mer	$550	$850	$1150
20 mer	$800	$1200	$1600

CAN YOU SYNTHESIZE & PURIFY PEPTIDES FOR LESS?

Before you buy an automated peptide synthesizer, you should consider the actual cost for in-house synthesis which includes the cost of reagents, personnel, service contracts, analysis, purification, waste disposal, laboratory space, downtime and, of course, the initial cost of the synthesizer.

Multiple Peptide Systems

10955 John Jay Hopkins Drive, San Diego, CA 92121 USA

Telephone (619) 455-3710
FAX (619) 455-3713
Outside California (800) 338-4965

MPS also provides a unique HF Cleavage Apparatus and a complete HF Cleavage Service.

WE'RE PROUD OF OUR PACKAGING.

IT MAY NOT LOOK LIKE MUCH TO YOU BUT... A USED BOX TO YOU MEANS 20,000 FEWER TO A LANDFILL.

At New England Biolabs, Inc., we are concerned about the environment and want to promote sound ecological practices. We urge you, too, to take a small but important step. For 14 years we have asked customers to "recycle" our styrofoam boxes. By reusing a box as many as 10 times, we keep more than 20,000 styrofoam boxes, per year, out of landfills and incinerators. (Stacked solid, that's the volume of a livable house!)

And to make return easier, all NEB boxes are delivered with a return postage paid sticker. Just tape the box closed and leave for the U.S. mail—ice packs and all. The cost of recovering our box through the mail is actually greater than the cost of a new box, but the savings are environmental. So, thanks for sending the boxes back.

Sequence 5kb Without Subcloning

Introducing the ExoMeth™* Sequencing Kit from Stratagene

- New Method for Sequencing DNA Utilizing 5-methyl dCTP
- A Revolutionary Sequencing Paradigm - 10 Fold Faster
- No Minipreps
- No Restriction Mapping Necessary
- No Oligonucleotides
- No Mung Bean or S1 Nuclease
- No Transformations
- Ordered Strategy, No Shotgunning
- Utilizes Double Stranded Templates
- Utilizes T7 DNA Polymerase or Reverse Transcriptase

Contact Technical Services for Stratagene's ExoMeth™ Sequencing brochure.

Announcing a unique RIA technology – it's in closer proximity than you think

- No liquid scintillation cocktails required
- Time saving
- Cost saving
- Increased safety
- High performance

Amersham introduces Scintillation Proximity Assays

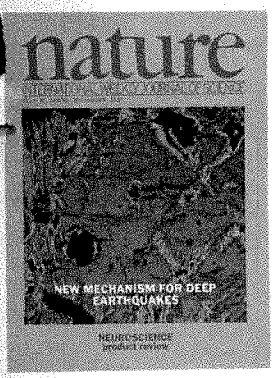
- No separation of bound from free required
- Simple to use; convenient protocol
- Readily automatable

Full details on the theoretical and technical aspects of scintillation proximity assays are given in our technical booklet 'Scintillation Proximity Assays — principles and practice', available on request.

Products available

- **Generic reagents** — for the development of in-house assays

	Ordering code
Scintillation Proximity Assay (SPA) reagent, anti-rabbit	RPN 140
Scintillation Proximity Assay (SPA) reagent, anti-mouse	RPN 141
Scintillation Proximity Assay (SPA) reagent, anti-sheep	RPN 142
Scintillation Proximity Assay (SPA) reagent, protein A	RPN 143



- **Assay systems**

6-Keto-prostaglandin $F_{1\alpha}$ [^{3}H] Scintillation Proximity Assay (SPA) system	TRK 952
Thromboxane B_2 [^{3}H] Scintillation Proximity Assay (SPA) system	TRK 951

Vol. 341 Issue no. 6244

◀ A cross-polarization micrograph of a crystal of olivine (blue) partially transformed to the spinel phase under stress. The small linear features (white bordered by yellow) are 'anti-cracks' normal to the greatest compressive stress, and may hold the key to the mechanism of deep earthquakes. Pages 733 and 687.

THIS WEEK

San Francisco

The long-feared earthquake on the San Andreas Fault struck in the evening rush-hour last Tuesday. See News pages.

Immune reactions

Following the recent discovery that the cyclosporin-binding protein cyclophilin is identical to a previously described peptidyl-prolyl *cis–trans* isomerase, a cellular binding protein for the new immunosuppressant FK506 is found to be distinct from cyclophilin but to have the same enzymatic activity. As well as having clinical importance in preventing allograft rejection, these drugs are revealing details of the lymphocyte activation process, pages 755, 758 and 692.

Progress report

The first practical applications of ceramic high-temperature superconductors are likely to be SQUIDS — superconducting quantum interference devices. If these new SQUIDS are to be competitive with conventional magnetometers, low intrinsic magnetic flux noise will be necessary. A thin film of $YBa_2Cu_3O_{7-\delta}$ has now been shown to exhibit such low noise (page 723). On page 725, detailed measurements of the current–voltage characteristics of bulk $YBa_2Cu_3O_7$ show that the critical properties of high-T_c superconductors cannot be fully explained by low-T_c theories.

Hot and cold water

How quickly is the global ocean warming? Conventional measurements from ships and buoys point to an increase in temperature of 0.05 °C per year, but satellite data have been interpreted as evidence for an increase of 0.1 °C per year. Reynolds *et al.* attempt to reconcile satellite and terrestrial data. Page 728.

On a microplate

Moai (stone statues) on Easter Island. The statues are carved from volcanic tuff, one of the eruption products of the proposed Easter hotspot. Another manifestation of the hotspot may be the formation of a tectonic 'microplate'. This microplate has now been comprehensively imaged by British and American sidescan sonars, as described in the Article on page 701.

Memory's made of this

Arachidonic acid facilitates a slow-onset, persistent increase in synaptic efficacy in the hippocampal dentate gyrus on weakly activating the perforant path. This is consistent with a 'retrograde messenger' role for arachidonic acid in the later phases of long-term potentiation, a widely studied model of the synaptic basis of information storage in the mammalian brain. Page 739.

Tandem turn off

The crystal factor of the *met* repressor DNA binding protein from *E. coli* reveals a conspicuous absence of the helix-turn-helix binding motif found in the structures of other bacterial DNA binding proteins. The protein recognizes specific sequences of DNA, turning off genes encoding for enzymes involved in methionine synthesis, by binding to them in tandem arrays. Pages 705 and 711.

Guide to Authors

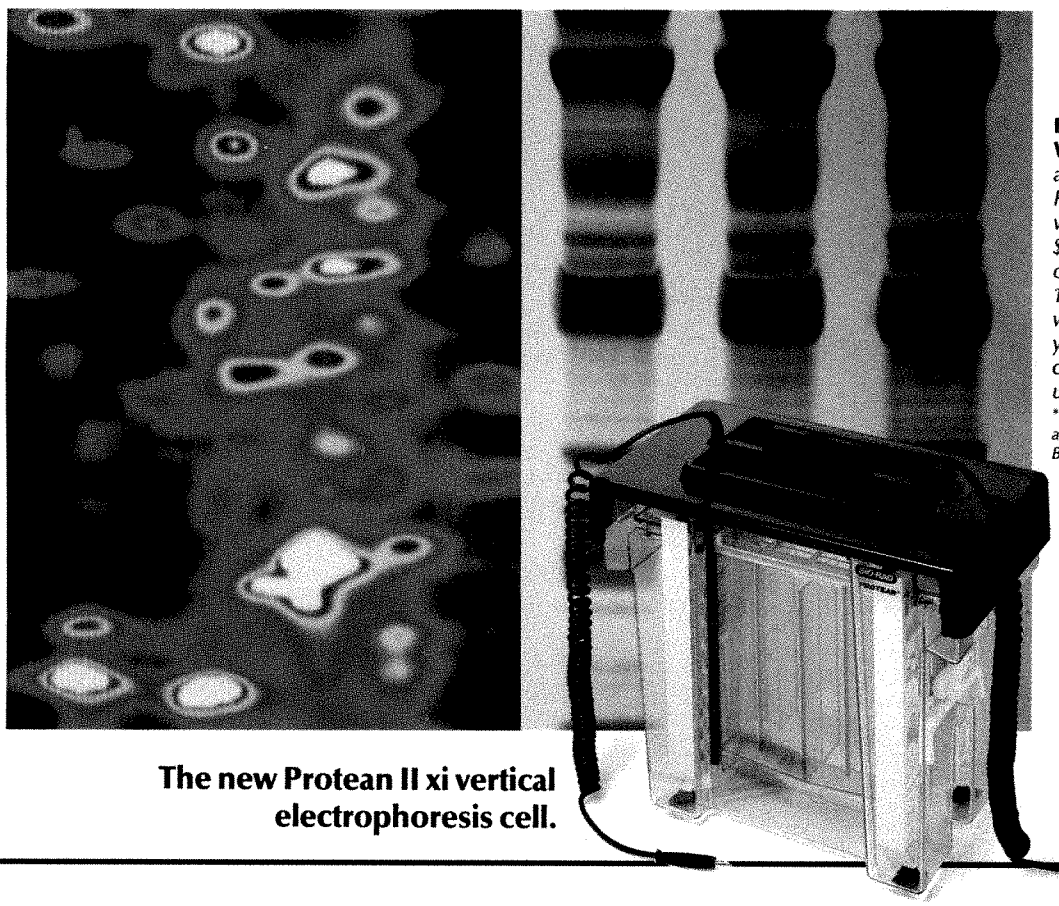
Why did we discontinue the world's most popular vertical electrophoresis cell?

Because we made it better!

Since its introduction in 1984, the original PROTEAN® II cell has enjoyed unparalleled success with more than 10,000 in use. However, good designs are not static, they evolve. Thanks to your input, we have made significant design and performance improvements.



- New state-of-the-art plastic construction for longer life, added strength, and improved chemical resistance.
- New reconfigured cathode for ultra-safe operation
- New alignment cards for greater convenience in assembly
- New softer gasket material for instantaneous leak-free sealing

Plus six other new features to improve ease-of-use, convenience, and versatility!

And, we've kept the features that made the original PROTEAN II cell such an outstanding success, including

- Unprecedented ease of assembly
- Leak-free casting without grease or agarose plugs
- Versatility—runs SDS-PAGE, preparative, gradient, 2D, native and high resolution nucleic acid agarose gels in 16 and 20 cm formats.

Bulletin 1466 tells more. Call or circle the reader service number.

The new Protean II xi vertical electrophoresis cell.

FREE PLATE WASHER? *Well almost. Get our new PROTEAN II xi plate washer system, a $195 value, for only one dollar ($1, 2 DM, 100 yen, 1000 lira,...)* with purchase of your PROTEAN II xi cell. Offer good until March 31, 1990.*

Bachem brings the price of high-quality peptides down to earth.

At Bachem, we believe our customers shouldn't have to pay high prices in order to get high-quality products.

That's why in the new Bachem catalog you'll find peptides of the absolute highest quality at the absolute lowest prices.

The 1989-1990 catalog features an extensive line of bioactive peptides and related products – more than ever before — including a wide selection of synthetic peptides, recombinant growth factors, and synthetic intermediates. Hundreds of new products. Thousands of reduced prices.

So call now for your free copy of the new Bachem 1989-1990 Catalog of Fine Chemicals. Discover page after page of high-quality peptides at prices that aren't sky-high.

One More Reason The ACAS 570 is...

The Cytometer for All Reasons

Reason #1 — Interactive Laser Cytometry

You command the power of the laser for new research capabilities such as sorting rare cells for cloning, fluorescence photobleaching, photoactivation, and cellular microsurgery.

Reason #2 — Quantitative Fluorescence Measurements

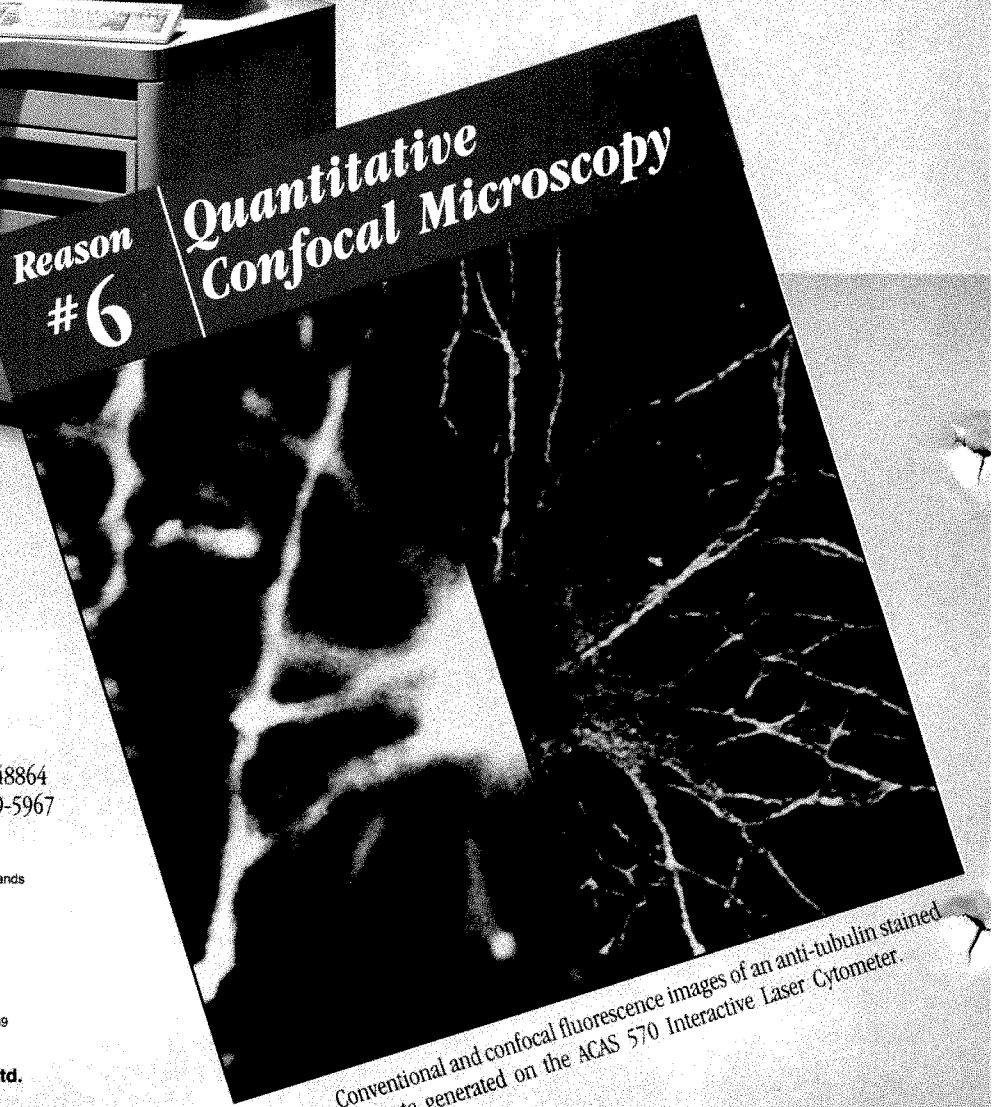
From single to dual label fluorescence measurements, you get **real numbers** for fluorescence quantitation ranging from cell-cell communication and molecular diffusion, to intracellular Ca^{2+} and pH.

Reason #3 — Sensitive Fluorescence Measurements

Advanced photometric detection and a focused laser spot give you reliable data from live cells with minimal photobleaching, and without the need for signal averaging.

Reason #4 — Comprehensive, Interactive Software

Powerful software teams laser cytometry with advanced computer technology — giving you integrated data acquisition, analysis, and management functions that are easy to learn, and easy to use. You also get a powerful assortment of application based programs specifically designed for the cell biologist.



Reason #5 — Versatile Integrated Instrumentation

From fluorescence imaging and cell cloning, to measuring transient Ca^{2+} and pH, the ACAS 570 provides the broadest range of cell and molecular biology applications available in a single instrument.

And now...the ACAS 570 gives you the exceptional resolution and contrast of confocal imaging.

Reason #6 — Quantitative Confocal Microscopy

Conventional and confocal fluorescence images of an anti-tubulin stained astrocyte generated on the ACAS 570 Interactive Laser Cytometer.

HYBAID™

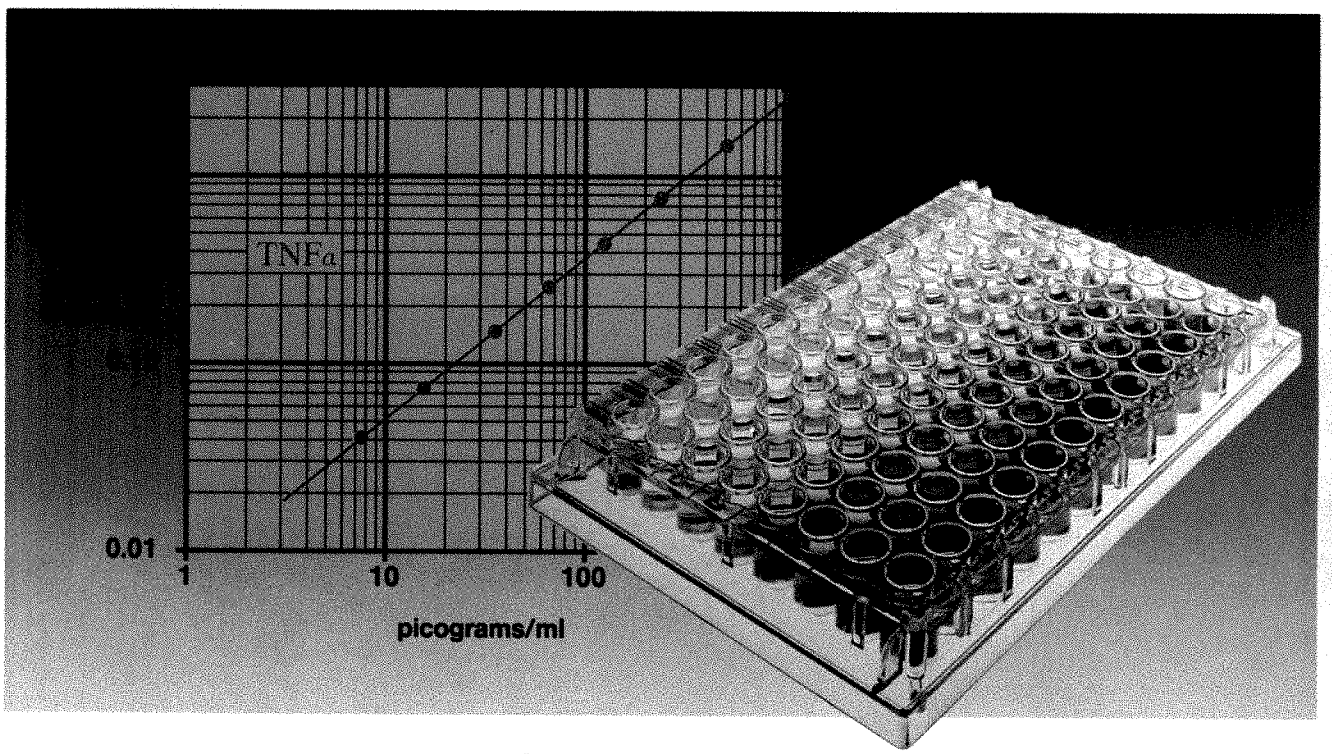
THE HYBAID THERMAL REACTOR

For Absolute Control of Temperature Cycling

WHY ABSOLUTE CONTROL?

The new Hybaid Thermal Reactor is a microprocessor controlled heating and cooling block designed to automate numerous molecular biology experiments. It may be operated by controlling the temperature of the low thermal mass copper block or uniquely by using a thermocouple located in a dummy tube to ensure absolute control of sample temperature.

The Thermal Reactor uses a novel and patented method of very rapidly raising and lowering the temperature that is elegantly simple in design and ensures excellent reliability. As there is no need for external cooling supplies it is virtually maintenance free.



- Faster cycle times.
  Maximum heating greater than 2.5°C/sec.
  Maximum cooling greater than 2.5°C/sec.
- Temperature range 4°C to 99°C.
- Absolute control of sample temperature.
  Remote sample thermocouple not only monitors, but controls the temperature and allows automatic ramping.
- High sample capacity takes 54 by 0.5ml microcentrifuge tubes.
- Very low sample temperature variation even at critical temperatures.
  Block uniformity +/- 0.5°C.
- Simple to program.
  25 programs available. Non-identical cycles, long dwell times, program hold, allows the most sophisticated protocols to be performed.
- Very safe to use.
  The permanent heat shield means block is never exposed.

Quantikine™

For the Precise Quantitation of Cytokines.

ELISA Kits for TNF-*a*, IL-1β*, IL-4*, IL-6

R&D Systems' Quantikine series of cytokine assays provides a sensitive, extremely accurate determination of the amount of a given human cytokine in cell culture media, sera and other fluids.

Each Quantikine kit features:

- A 96 well, 12 strip plate, *pre-coated* with a monoclonal capture antibody.
- A directly conjugated detection antibody.
- Complete reagents for testing of serum and tissue culture samples.

FOR RESEARCH USE ONLY
NOT FOR DIAGNOSTIC OR THERAPEUTIC PROCEDURES
*Available October 30, 1989

Sensitive: linear in the range of 20-2000 pg/ml; minimal detectable amount <10 pg.

Precise: well-to-well CV <8%

Specific: results not influenced by the presence of other cytokines.

Accurate: eliminates the inherent imprecision of bioassays.

Rapid: simple 7 step procedure, data in <4½ hours from receipt of kit.

Add sample...Incubate (2 hours)...
Wash...Add Detection Antibody...
Incubate (2 hours)...Wash...
Develop...Read Results.

Another new *Taq* sequencing solution by Promega.

TaqTrack™ Sequencing System

Sequence of M13mp18 on a 6% polyacrylamide/7M urea gel using the pUC/M13 forward 24mer primer and [α-^{35}S]dATP.

Two Solutions to Sequencing Difficult DNA Templates.

Choice of 2 protocols:

- End label protocol for sequencing ssDNA and dsDNA templates including lambda DNA and amplified DNA
- Two-step internal labeling protocol which allows you to take advantage of the properties of ^{35}S for sequencing ssDNA

Both protocols offer these benefits:

- Sequence at 70-90°C with thermostable *Taq* DNA polymerase
- Solve difficult template problems
  - GC-rich templates
  - Long hairpins
- Observe consistent band intensity
- Actually read from 1-500 bases
- Avoid lengthy chemical methods

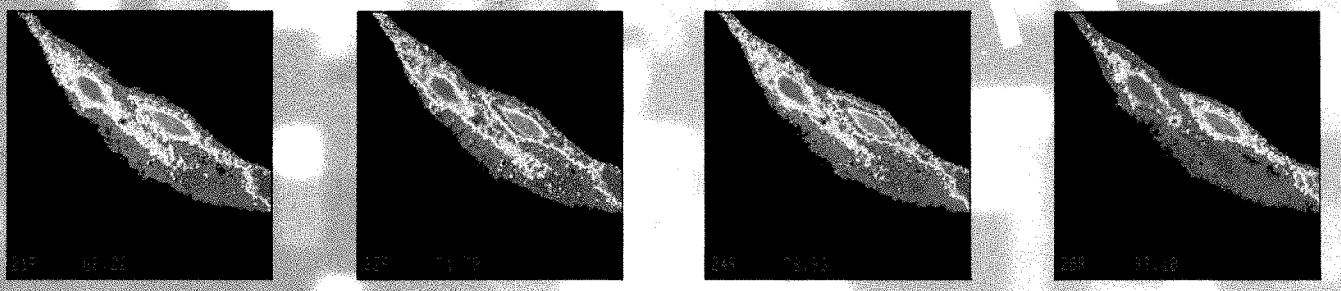
DYNAMIC VIDEO IMAGING



Presents

A MINUTE IN THE LIFE

OF A

SMOOTH MUSCLE CELL

The new MagiCal system from Joyce-Loebl allows scientists to visualise and quantify dynamic changes in cellular activity - from intracellular ionic concentration to cell surface antigens and more. Your imagination is the only limit. MagiCal provides the latest technology; real-time, low light level video image capture, averaging and ratioing, and storage in fast memory, on video tape or on optical disc. This highly integrated system of software and hardware offers the ability to digitise and store images at up to four wavelengths in successive video frames, enabling the use of multiple fluroescent probes for cellular function. MagiCal also provides an unparalleled array of user-friendly features for qualitative and quantitative analysis to enable spatial and temporal inspection of fluorescence changes down to the single pixel. Powerful computer-based graphical and image montage tools permit construction of high quality presentation material, and allow export of raw data into statistical and spreadsheet programmes of your choice. MagiCal offers a unique environment for this new, vital and fast-changing area of research. Where scientists have a need, Joyce-Loebl leads the way.

COMPLEX CARBOHYDRATE STRUCTURAL DATABASE AVAILABLE FOR DISTRIBUTION

A complex carbohydrate structural database (CCSD), with over 2,000 entries of structures and associated text files, and CarbBank, the computer program that enables investigators to search and manipulate the database, can be purchased as of October 1, 1989. CarbBank and the CCSD were developed under the auspices of a 14-nation Board of Directors. The entries have been provided by some 26 curators expert in such areas as *N*- and *O*-linked carbohydrate chains of glycoproteins, glycolipids, and bacterial and plant polysaccharides. It is anticipated that the database will contain over 4,000 entries by the end of 1991 and all published oligosaccharide structures soon thereafter.

CarbBank and the CCSD can be operated on IBM-compatible PCs with 540 Kb of free RAM, and will be supplied on either 5.25 or 3.5 inch disks. An operator's manual is provided, and technical assistance is available by telephone, mail, Bitnet, or FAX.

The purchase price of the CarbBank program includes updates through September 1991; the annual purchase price of the CCSD includes one free six-month update. Academic and government employees can purchase the CarbBank program for $250 and the CCSD annually for $250. This price allows the program and database to be used by one research team (a maximum of 15 individuals). The price for corporations for each of their research or business sites is $1,000 for the CarbBank program and $500 annually for the CCSD. A demonstration program containing a few structures and the search routine can be obtained for $25. (This project has been sponsored by DOE/NIH grant # DE-FG09-88ER13970.) **Reader Service No.51**

Mechanisms of Drug Action on the Nervous System

Second Edition

R. W. RYALL

This completely updated and revised new edition examines the mechanisms by which drugs cause their therapeutic or undesirable side-effects in the brain. Drug actions are examined mainly at the cellular and subcellular level and are related to the underlying physiological and pathological processes.

Pergamon - leading the field in

Two major journals with increased frequencies for 1989...

NEUROSCIENCE

An International Journal under the editorial direction of IBRO

Chief Editors: **P G KOSTYUK**, *USSR*, **R LLINAS**, *USA* and **A D SMITH**, *UK*

Neuroscience, under the editorial direction of the International Brain Research Organisation, is one of the leading journals in its field. Truly international in scope, the journal publishes papers from all parts of the world, and has a distinguished international editorial board, which includes specialists in all areas of neuroscience, in order to ensure a high standard of publication.

Neuroscience publishes papers describing the results of original research on any aspect of the scientific study of the nervous system. The observations in the papers are clearly and succinctly reported so as to be readily comprehensible to scientists of other disciplines.

Subscription Information
1990: Volumes 34-39 (18 issues)
Annual subscription DM 3255.00

NEUROPSYCHOLOGIA

An International Journal in Behavioral Neuroscience

Editor-in-Chief: **M JEANNEROD**, *France*

Neuropsychologia is an interdisciplinary journal of the neurological, medical and behavioral sciences. It is devoted to promoting the study and understanding of human behavior from a neurological point of view, and to integrating clinical, genetic and experimental contributions into its field.

Now published monthly, *Neuropsychologia* also presents papers focusing on the analysis of disorders of perception, action, intelligence, memory and language resulting from injury or disease of the cerebral cortex.

Special issues have dealt with subjects such as methods in neuropsychology, selective visual attention, and memory. A forthcoming special issue will cover developmental plasticity and recovery of function.

Subscription Information
1990: Volume 28 (12 issues)
Annual subscription DM 1270.00

Reader Service No.20

IT IS NOT WORTH TAKING THE SHOT IF YOU ARE UNCERTAIN ABOUT THE QUALITY OF YOUR PEPTIDES.

You can waste a lot of time, effort and money on your research if you are not sure about the quality of your peptides. At NEOSYSTEM we feel you should not have to make the choice between price and quality. Thanks to our multi-peptide synthesiser developed in house, we are able to produce many different peptides simultaneously. This means we can offer high quality peptides at low costs with short delays. Contact us now to discuss your custom peptide requirements.

3 levels you can choose from :

GOLD	minimum 98 % pure 900 * FF/residue	HPLC profile, amino acid analysis sold by net peptide weight 15-20 mg
SILVER	minimum 85 % pure 650 * FF/residue	HPLC profile, amino acid analysis sold by net peptide weight 25-50 mg
BRONZE	minimum 60 % pure 400 * FF/residue	1 step purification , 200-300 mg

* all prices +/- 20 % depending on sequence and amount required.

Experience Magical Power

New Silver Staining kit
for Polyacrylamide Gel

Two dimentional electrophoresis (human serum)
2D · SDS-PAG PLATE 10/20 (code No. 120483)

It's fast and easy!

Easy 10 steps of procedure completes staining in just over 1 hour.

It's beautiful!

Proteins are stained evenly and uniformly while providing high contrast against clear background for improved resolution.

It's versatile!

Plastic or glass supported gels and IEF gels can also be stained just as beautiful as regular PAG plates.

It's free from overstaining!

You don't need to watch developing image every second. Yet, you will never overstain your gels.

Essential Research Journals from Churchill Livingstone . . . .

MEDICAL JOURNALS

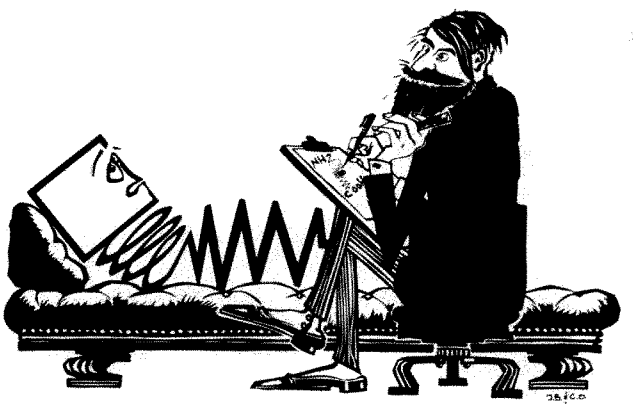
Churchill Livingstone have a well known and established list of medical journals including the **prestigious research journals** listed below.

Cell Calcium **Editors: R M Case and A Scarpa**, publishes work from all branches of science and medicine on the regulation of cell calcium or the regulation by calcium of cell function. Papers are refereed and published rapidly, providing the latest discoveries in the field.

Neuropeptides **Editors: M J Brownstein and J Hughes**, presents original research and review articles on all aspects of the biology and chemistry of peptides derived from, or acting on, the nervous system. Providing the essential resource for researchers in neuroscience, neurology, endocrinology and pharmacology.

Prostaglandins, Leukotrienes and Essential Fatty Acids. **Editor: D F Horrobin** The scope and depth of the journal is now greater than ever before with high quality papers, including some review articles, on all aspects of prostaglandins, leukotrienes and essential fatty acids. Now publishing 12 issues a year.

New for 1990. . .



Lithium. **Editor: F N Johnson.** This new journal will publish selected high quality articles on all biomedical aspects of lithium, i.e. biochemical, physiological, pharmacological, psychopharmacological and clinical. The aim of Lithium is to provide a single outlet for these varied research themes, and so to unify the subject of lithium research and therapy. Published articles will represent important new directions in the study of biological effects of lithium.

If you would like any further information on these or any of our journals please contact: Suzanne Casey, Sales Promotion Executive, Churchill Livingstone Medical Journals, Robert Stevenson House, 1-3 Baxters Place, Edinburgh, EH1 3AF. UK

Understanding Insulin Action

Principles and Molecular Mechanisms

Edited by J. ESPINAL, Director of Endocrinology, Glaxo Research Laboratories, North Carolina, USA

Reviews the physiological effects of insulin, the pathology associated with it and the current views on the molecular mechanisms of its action. It presents current knowledge of the insulin receptor and its role; and shows how hormones and other agonists communicate their messages into the inside of a cell. The effects of insulin on two familiar systems of transmembrane signalling (cyclic AMP and inositol phosphates) are presented, before a third and novel signalling system (uniquely involved with insulin) is discussed: the inositol-phosphoglycan messenger and its role in insulin action are included here.

Carbohydrate Recognition in Cellular Function

Ciba Foundation Symposium 145

Chairman: E. RUOSLAHTI, La Jolla Cancer Research Foundation, California

Cells interact with their environment and with neighbouring cells by an intricate array of molecular recognition events. This book explores the role of carbohydrates in communication between cells of multicellular organisms. The thermodynamics and spatial restrictions of oligosaccharide-protein interactions are discussed. An analysis of the amino acid sequences required for carboyhdrate recognition and the use of a consensus sequence to identify potential caboyhdrate-binding proteins are described. Modification of the carbohydrate moiety of glycoproteins is a frequent occurrence in certain diseases, including those of the immune system. Recent progress in understanding all these areas is described. The discussions after each presentation highlight work that remains to be done.

Floods

Hydrological, Sedimentological and Geomorphological Implications

Edited by K.J BEVAN, Department of Environmental Science, University of Lancaster and P. CARLING, Freshwater Biological Association, Cumbria, UK

This book is based upon papers presented at the BGRG Meeting of the same name, held in 1987 at the University of Lancaster. The topics covered include the latest developments in describing flood flow generation, interpretation of flood sediments, reconstruction of flood magnitude and other aspects of floods, as well as an assessment of the effects of floods within the framework of longer term landform evolution Contributors are from a range of disciplines, but have a common interest in the dynamics of fluvial floods and their effect on the landscape.

Auditory Function

Neurobiological Bases of Hearing

Edited by G.M. EDELMAN and W.E. GALL, both the The Rockefeller University, New York, USA and W.M. COWAN, Howard Hughes Medical Institute, Bethesda, USA

Recent advances in anatomical physiological, and psychophysical techniques and new formal analyses have made considerable advances in integrating the various aspects of hearing. Consisting of five sections, this volume begins with development and proceeds from the periphery to the highest psychological functions reflected in speech and guided behavior. In the first section the developing auditory system is considered; in Section Two cochlear neurobiology and current theories of cochlear mechanics are reviewed. Section Three deals with the response properties and electrical characteristics of auditory neurons. Section Four discusses the models of peripheral and central factors in intensity perception, auditory masking and spectral shape discrimination. The final section examines auditory neuroethology and speech processing.

Pest Management in Cotton

Edited by M.B. GREEN, Independent Consultant, formerly ICI Limited, and D.J. de B. Lyon, Overseas Development of Natural Resources, Porton Down, Wiltshire, UK

Cotton is a vital crop worldwide, which has many pest problems: this book brings together leading scientists in pest management in cotton from the USA, the UK, Europe and Japan, to discuss the latest research and exchange opinions on this topic. The authors cover the use of a range of conventional pesticides, the application of these pesticides, and resistance problems and their management. They present alternative control methods and review the economic aspects of pest management strategies.

Methods for Assessing and Reducing Injury from Chemical Accidents

SCOPE 40

Edited by P. BOURDEAU, Commission of the European Communities, Brussels, and G GREEN, School of Hygiene and Public Health, The Johns Hopkins University, Baltimore, USA

The occurrence in the last two decades of a series of catastrophic events involving the accidental releases of toxic chemicals has underscored the urgency of devising more effective measures for their prevention and mitigation of injury caused by them. The need is much greater however for developing methods to repair the damage inflicted by the release of chemicals on human health and the environment. With the publication of this monograph, the reader is provided with a forum for the exchange of scientific ideas in extremely difficult areas of chemical safety programmes. The book is a source of critical information for those in government and industry who have to deal with emergencies and accidents involving chemicals.

Nerve Growth Factors

Edited by R A. RUSH, Department of Physiology, Flinders University Medical School, South Australia

This volume covers a diverse range of techniques currently being used in many laboratories worldwide to study both the nerve growth factor (NGF) molecule as well as several newer growth factors, active on a variety of nerve populations The authors of each chapter are recognised leaders in their field and they provide detailed protocols that will allow any laboratory to establish the procedures without reference to other texts. Most of the book focuses on techniques which are relatively new. It also provides updated and improved versions of procedures which have been available for some time.

0471921459 376pp March 1989 £47.50 A Wiley UK Title

Drug Carrier Systems

Edited by F H.D. ROERDINK, and A.M KROON, Laboratory of Physiological Chemistry, University of Groningen, The Netherlands

The book presents a recent overview on drug delivery by means of carrier systems. The aim of this approach is to optimise the action of drugs. This can be achieved by various mechanisms such as increased uptake by diseased target tissues, reduced side effects by sustained release and prevention of drug inactivation by encapsulation of the drug within a carrier. Early chapters deal with the basic philosophy of drug targetting and a general overview of current progress. Clinical applications are discussed and the application of implantable infusion pumps for drug delivery in man is critically reviewed.

PCR Primer Selection Program

Save time and avoid costly mistakes with a new IBM/PC program that scans flanking sequences for the "optimum" PCR primers.

☐ Simple sequence entry, editing, inversion, complementation and verification.

☐ Automatic search of thousands of possible primer sequences.

☐ Checks primers for
- Primer/primer annealing
- Primer-dimer formation
- GC content
- Runs of identical bases
- Secondary structure

☐ Self-explanatory, extremely easy to use.

☐ Costs less than a pair of oligonucleotides (£95 or $US165).

Embryo research and abortion

The British government's promised bill on embryo research, now imminent, seems bound to provoke an unwanted argument on abortion. But it is not too late to amend the bill and make it better.

ONE consequence of the British government's delay in bringing forward its promised bill to implement the recommendations of the Warnock committee on *in vitro* fertilization (IVF) and related matters is that opponents of legalized abortion have had time to organize themselves so as to seize the opportunities with which the bill will provide them. The bill will be part of the government's legislative programme for the next parliamentary session, due to be announced by the Queen next month. Meanwhile, the government has leaked news of its willingness that the time-limit for abortion should be reduced from 28 to 24 weeks of gestation. That is a sensible step, although it will not, unfortunately, satisfy the critics of abortion.

That the two issues are connected is uncomfortably undeniable, at least on a strict reading of the Warnock recommendations. The committee, faced with the need to say when it would be permissible to persist with the observation of artificially fertilized human embryos, recommended that all such research should require the approval of a new statutory body, but that in no case should embryos remain viable for more than 14 days. That time was chosen to be less than that at which, in the normal embryo, the nervous system begins to develop. Ostensibly, such an immature embryo could not be supposed to feel pain. More primitively, but excusably, the members of the committee took the view that the central nervous system is the embodiment of the soul. The obvious difficulty is that anti-abortionists are entitled to demand that naturally fertilized embryos should have the same protection as Warnock recommends.

This is a debating point, but none the less influential on that account. The underlying difficulty is that the Warnock recommendations over-insure against the abuse of human embryos by researchers. That there should be a statutory procedure by which all investigations must be approved is undisputed. By now, thanks to the experience of the committees regulating the development of the genetic manipulation of organisms, there is ample experience that statutory procedures can work efficiently and in a manner that commands the respect of researchers. What reason is there to fear that the proposed replacement of the present committee on IVF by a statutory body will be less well organized? And what reason can there be for supplementing that statutory regulation by the arbitrary requirement that no observations of an artificially fertilized embryo should extend beyond 14 days?

The public interest that human embryos should be accorded the respect they deserve, and the Warnock committee's inclinations, could just as well be secured by requiring that the new statutory committee should be satisfied that any proposed observation on or experiment with an artificially fertilized embryo should build on knowledge already firmly established, that there is a high chance that they will yield the information expected of them and that that information, if gathered, would contribute in some substantial way to the understanding of the distinctive characteristics of human life and its preservation in a healthy state. Working with such guidelines, no statutory committee would be likely to sanction the study of a human embryo when, for example, a mouse embryo would suffice. That is why, even at this late stage, the government should scrap the arbitrary time limit wished on it by the Warnock committee. □

California lessons

Earthquake protection is plainly possible, as the Californian earthquake showed. But who else can afford it?

CALIFORNIANS are almost as taken aback that last week's earthquake should have killed fewer than 200 people as by the circumstance that there should have been a further relief of stress on the San Andreas Fault (see pages 676 and 677). In spite of the tragedy that now afflicts the families bereaved and, many more, those without housing, it is literally astonishing that an urban earthquake essentially of the same magnitude as that which killed 25,000 people in Armenia last December should have done so little damage.

The explanation is simple: California's building codes, which the state has been progressively tightening since the San Francisco earthquake of 1906. The codes have been developed so that San Francisco and Los Angeles now sport metropolitan cities' shares of tall buildings, but there has also been immense attention to detail. Just five years ago, owners of wooden frame buildings were required to bolt them to the concrete foundations on which they rest when it emerged that structures of that kind could easily be shaken off their pedestals by sufficiently strong earthquakes. The regular rehearsals of the

emergency services also did much to diminish the consequences of last week's major shake.

The most serious danger now may be complacency. The relief of stress along the San Andreas Fault at San Jose cannot but increase stresses on other locked sections of the fault. But which of them will rupture left is anybody's guess. Yet there is bound to be a tendency to suppose that San Francisco's surprising escape last week is a sign that the building codes are sufficiently stringent as they are. But they are not. Plainly, there is room for the improvement of public services, electricity and water, for example. The spectacular collapse of a mile-long section of the double-decked Interstate 880 at Oakland is a less serious problem.

Meanwhile, California's experience last week should be a lesson for others to take to heart. Tokyo and other Japanese cities, at much the same risk as San Francisco, have also been zealous in earthquake protection but will nevertheless have much to learn from last week's earthquake. But most of the other regions of the world at risk from earthquakes are, by comparison, almost unprotected. Armenia's experience last year demonstrates that, but even European countries such as Greece and Turkey are well behind California. And what is to be said of the earthquake zones of the Indian subcontinent, the southeast Pacific and the Andean zone of South America, where the primitiveness of buildings dictated by poverty seems to be the best protection? Mainland China is an even worse case, if only because seismic risks are more generally spread than elsewhere. Where are the funds to carry California's message to these places?

It would be different if methods of predicting earthquakes were in sight, but they are not, even in California. That is why the earthquake-ridden peoples of the world will sooner or later have to stomach the cost of following suit expensively on humdrum building codes. The aid community had better take note of that before too much more time has passed. □

Research by numbers

British research councils may have sacrificed too much autonomy for administrative flexibility.

THE Wellcome Trust, the British charitable foundation, has imaginatively stepped into the vacuum left by the British government's unwillingness to support the proposed study of sexual behaviour of the British population, and has offered a grant of £900,000 to allow the planned survey to be completed (see page 675). The speed of the trust's response is especially admirable. Now, the momentum of a worthwhile venture will not be dissipated. Although the immediate objective of the survey is to gather information bearing on the assessment of the risk that AIDS will spread, the survey will also throw light more generally on the sexual behaviour of a sophisticated population and, the uncertainties of surveys of this kind notwithstanding, should provide a more conspicuous landmark than Kinsey's US studies in the 1950s. The money will not be wasted.

Meanwhile, the means by which the British government refused to back the grant deserve more attention than they have been given. The researchers responsible for the project have been working through the Economic and Social Research Council (ESRC), the smallest of the five supposedly autonomous research councils responsible for supporting basic research in Britain. Knowing that ESRC's purse was shallow, they had sought also to interest the Department of Health and the Health Education Authority, both of which are said to have been sympathetic to the proposal. But in the end, after months of temporizing, the government, apparently in the person of the prime minister herself, said no. By what right, it may be asked?

The explanation seems to lie in the agreement reached in June this year between the Department of Education and Science (DES), which handles the British science budget, and the research councils. Most of the agreement makes sense. The research councils, for example, are given the right to carry forward 2 per cent of their expenditure from one year to another. They are also free to make grants in excess of £50,000 without seeking formal approval from the DES (the limit is now fixed at 3 per cent of gross expenditure). In return, the councils agreed to a number of requirements of the government, some of which are largely formal (the research councils undertake to "increase the quality and utility of postgraduate research", for example), but some of them are intolerably irksome.

The government's interference with the proposed survey of sexual behaviour among the British thus appears to derive from the stipulation that the government should be consulted whenever research councils plan grants "liable significantly to involve Ministers including highly contentious and politically sensitive matters of moment and matters of Ministerial resolution". The same agreement says that the research councils will refer to the DES grants "interacting significantly with other domestic policies of Government, particularly if at variance with them".

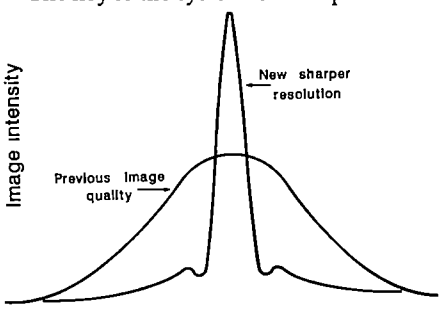
Nobody will complain that the government should have a say in major international issues, continued British membership of CERN for example, but, taken together, these requirements constitute a high price to pay for the loosening of the administrative shackles that have irked the research councils for decades. As the AIDS survey has shown, the requirement is a licence for government squeamishness. In principle, it also restrains ESRC from backing research proposals designed to investigate the good sense of the Treasury's commitment to 3 Deutschmark to the pound sterling. This, for what it is worth, is a further reason for the reorganization of the research councils under a single umbrella; then it might be possible to make a stronger fight to clothe titular autonomy with some of the reality thereof. □

Adaptive optics shown on French telescope

■ Theoretical image quality approached

■ Development on schedule for VLT Telescope

Garching, near Munich



ON THE night of 12 October, astronomers at the European Southern Observatory (ESO) took a big step towards realizing the dream of effectively stripping away the distorting effects of the Earth's atmosphere. In a successful test of a technique called 'adaptive optics', developed by ESO with French colleagues from the Observatoire de Meudon, the Laboratoire de Marcoussis and the research centre ONERA, a dancing, bobbing image was reduced to an almost stable spot. The test also bodes well for the European Very Large Telescope (VLT), an innovative linked array of four 8-metre telescopes to be built in Chile.

The advance is a first step towards making adaptive optics — in which secondary mirrors are physically moved to compensate for atmospheric motions that disturb a star's image — a routine feature on future optical telescopes. It has yet to be shown that the ESO system will work on any optical telescope, or that it will be as successful at visible wavelengths as it is in the near infrared. But if development goes as quickly as the ESO staff expects, adaptive optics could transform not only future telescopes but existing ones as well. ESO director Harry van der Laan said that a telescope 4 metres in diameter with adaptive optics would produce images as good as an 8-m telescope without the system.

Fritz Merkle of ESO and collaborators performed the test on a 1.52-m telescope at the Observatoire de Haute-Provence in southern France, where light pollution and low altitude translate into mediocre image quality. The new system not only took care of atmospheric distortions but also corrected for an inherent aberration in the optics of the telescope. Image quality improved slightly at visible wave-lengths and dramatically in the infrared. The best results, which came at a wave-length of 3.5 to 5 micrometres, clearly showed a diffraction ring around the star image, meaning that the image quality approached the theoretical limit for a ground-based telescope.

Adaptive optics is analogous to active optics, another technology developed at ESO and installed on the ESO 3.58-m New Technology Telescope in Chile. In both cases, a feedback loop using an electronic image analyser improves the sharpness of the images by bending a mirror. But active optics operates on a timescale of seconds or minutes, whereas adaptive optics responds in milliseconds, fast enough to correct for the fluttering of images caused by the atmosphere. Active optics moves the telescope's primary mirror, whereas adaptive optics shunts the light from the primary mirror to a smaller mirror that can be adjusted more rapidly by small motor-driven supports.

The key to the system is a computer that

Sketch of the improved resolution achieved in the infrared using adaptive optics. The two satellite peaks correspond to the diffraction ring around the image

processes a digital form of the distorted images and adjusts a deformable silicon mirror 1 mm thick. The adjustment improves the image before it is recorded by an electronic camera or a spectrograph. Developing special algorithms and dedicated hardware for the computer was the greatest technical problem, said Merkle.

The gamble taken by ESO in 1985 when it decided to rely on adaptive optics for the VLT seems to have paid off. Although considerable improvement is still needed, van der Laan is confident that they will be ready for installation on the VLT.

By collaborating with ESO, the French hope to add to their expertise and their reputation in the adaptive optics field. By contrast, the US military is thought to have been working for years on adaptive optics technology for the purpose of satellite tracking and laser weaponry without sharing any of its knowledge with astronomers. The most ambitious civilian programme was dropped recently by the National Optical Astronomy Observatories in Tucson, Arizona, because of lack of money and personnel.

Merkle estimates that the mirror and computer technology could be constructed from available components for as little as DM500,000 ($270,000) per system, excluding the huge cost of software development. This is a relatively small amount in the context of ground-based telescope projects; by contrast, space-based telescopes would be "hundreds of times" more as expensive. **Steven Dickman**

AIDS RESEARCH

Sex survey gets Wellcome support

London

A NATIONAL survey of British sexual behaviour, intended to provide data that will shed light on the transmission of the human immunodeficiency virus (HIV) and the spread of AIDS, will now go ahead, despite being vetoed by Prime Minister Margaret Thatcher (see *Nature* 341, 181; 1989), on the strength of a £900,000 grant from the Wellcome Trust, Britain's largest medical charity. Peter Williams, director of the Wellcome Trust, said the trustees agreed to support the study because "the results will be of great importance and of the highest scientific quality". Thatcher had refused to fund the survey because she felt it was "too intrusive", although the Economic and Social Research Council (ESRC), the Health Education Authority (HEA) and the Department of Health had supported the project.

Roy Anderson, a professor at Imperial College who helped to organize the survey, expressed great delight at the news and said the trust had acted both generously and swiftly. The survey will start in January. The research will be carried out by the department of genito-urinary Medicine at University College and Middlesex School of Medicine, the department of public health and biology at St Mary's Hospital and Imperial College, and the independent organization Social and Community Planning Research.

Detailed information on people's sexual behaviour and their attitudes to sex will, said Anderson, help to estimate the two main parameters that determine how fast, and among what part of the population, HIV spreads: these are the rate of infection and the rate of acquiring new partners. The survey will also yield valuable information about the incidence and transmission of other sexual diseases and cervical cancer.

Ben Webb

SPACE

Galileo takes off at last

Washington

ON Wednesday, 18 October, the spacecraft Galileo finally began its six-year journey to Jupiter. The space shuttle Atlantis took off after one more day of delay, due to weather, at 12.53 p.m. About seven hours later Galileo, released from the shuttle cargo bay, was steered by its own booster onto a path towards Venus. Rounding Venus and skirting Earth twice, Galileo will pick up enough velocity to reach Jupiter towards the end of 1995.

David Lindley

Erratum: THE amount of plutonium on board Galileo is not 100 kg as reported in *Nature* (**341**, 374; 1989). The correct amount is 50 lbs, which should be divided, not multiplied, by two, to give approximately 25 kg. □

LOMA PRIETA EARTHQUAKE

Bay area laboratories do well

San Francisco

RESEARCH facilities at universities and national laboratories in the San Francisco Bay area fared well in the earthquake of Tuesday 17 October and subsequent aftershocks, in many cases because buildings were new or had been reinforced after previous upheavals.

The University of California at Santa Cruz, just a few miles from the earthquake's epicentre, was one of the institutions hardest hit. But because it rests on a hill above the town, the university suffered less than Santa Cruz itself, which is largely built on loose soil in the flood plain below. Residence halls were evacuated for only a few hours, and most facilities were soon functioning normally.

But the four major science facilities, including the new Sinsheimer Laboratories building scheduled for dedication later this month, suffered considerable interior damage, including chemical spills and broken laboratory equipment. By Friday, three had been declared safe, both structurally and with regard to hazardous materials, but Natural Sciences II, which houses astronomy, physics and some chemistry and biology, was still being evaluated.

Although it escaped structural damage, the Stanford Linear Collider (SLC) suffered some minor power failures, leaks in some fluid lines, and a break in a vacuum chamber. Fortunately, SLC was in the middle of a shutdown and no beam time was lost. Had the collider been running, said spokesman Michael Riordan, "the beam would have hit the wall somewhere and everything would have shut down because of the control system".

The biggest concern is that some of the 1,000 beam-guiding magnets have probably been thrown out of alignment. Next week, surveying crews will check the magnets; if too many are misaligned, the whole machine will have to be reconfigured. A preliminary laser-beam measurement has indicated that some segments of the accelerator may have shifted, although only by 100 micrometres, which is at the limit of detectability. Whether or not this is due to the earthquake is not yet known.

Stanford University itself was probably the hardest hit university in the area, and estimates damage at $160 million. Twenty-five out of 240 major buildings have been shut, 12 of which are residence halls. Memorial Church, in the centre of campus, will be closed indefinitely. The keystone, the critical block in the archway near the altar, has moved by more than half an inch, and the church will probably need large-scale structural repairs.

Several other buildings were damaged to varying degrees, but Stanford had reason to be grateful for a 1988 report, *Earthquake Risk Management Report*, which paved the way for a series of structural modifications. Two older buildings, Roble Hall and the Old Pavilion, were furnished with seismic bracing just a few weeks before the earthquake.

Science facilities fared better. There was broken glass, overturned bookcases and damage to light fixtures, and some experiments were set back for a few days. But for the most part, no major equipment was destroyed. The one exception was the Keck building, the first completed facility in the new Near West campus science complex. The building itself held up well, but as much as $30,000 worth of equipment may have been lost.

At the University of California at Berkeley, there was minimal structural damage. A few cracks appeared in various buildings, but no scientific facilities, including the seismographic station, were disrupted. At classes were officially closed.

Above the campus, the Lawrence Berkeley Laboratory (LBL) suffered no structural damage, LBL's automatic system shut down gas valves, and a few buildings had trouble starting services up again. But otherwise, no problems were reported. All three accelerators are operating.

Lawrence Livermore National Laboratory also withstood the earthquake well. After two buildings were destroyed in 1980 by an earthquake of magnitude 5.9 with the epicentre just a few miles from the laboratory, $25 million has been spent in seismic upgrades. This included reinforcing buildings and putting doors on cabinets containing chemicals. The most serious damage was a flood in Building 41, a laser facility, as a result of broken water pipes.

Finally, the University of California at San Francisco reported no big upsets — a few chemical spills, some cracked walls, but no significant structural damage.

Robert Buderi

The physics of destruction

San Francisco

THE fact that some areas suffered considerable damage while others escaped almost unscathed is no cause for surprise. According to Robert Page, a geophysicist with the US Geological Survey in Menlo Park, one of the major factors was "liquefaction", which occurs in sandy material that is saturated with water. The earthquake's vibration transforms such material into a slurry: because the sand particles are all about the same size, they lose contact with each other, water flows between them, and mobile near-liquid is formed. This is what happened in San Francisco's most devastated area, the Marina district, which is built largely on land-fill. The hilly areas rest on bedrock, which is much less susceptible to disruption.

In Santa Cruz, the buildings hit hardest were those of unreinforced masonry situated on the flatland in the centre of town, which lies on a flood plain. Page said a similar story probably unfolded there, exacerbated by the fact that in an earthquake ground tends to move horizontally towards rivers.

A second factor contributing to the wide variation of damage is building resonance. If a building's own natural frequency of vibration closely matches that of the driving force applied by the seismic waves, the resonance amplifies the motion, making the structure more likely to tumble. Close to the epicentre, where shock waves are of higher frequency, resonance is more likely to strike low-lying structures, explaining why, in areas such as Santa Cruz, many houses in the flatlands were knocked off their foundations. Further away, as in San Francisco, the seismic waves are of lower frequency, and resonate with taller buildings, but in the city such structures are built to cope with earthquakes of this magnitude. They also have deep foundations that extend past the loose topsoil and into hard ground below.

Edward Wilson, a professor of civil engineering at the University of California in Berkeley who specializes in the response of buildings to earthquakes, observed that although resonance and liquefaction are important, "clearly, if you look around, the site is the most critical element". Hard sites, such as the hills of San Francisco, afford little amplification of a seismic wave; softer soil, even if liquefaction does not take place, will amplify the waves.

This probably holds true even for the Cypress section of Interstate 880 in Oakland, where a still undetermined number of people died. An upper section of the double-decker freeway collapsed onto the lower deck, because supporting columns gave way. The freeway was built in the 1950s, and the structure had been only partially strengthened since then: the cross-links that keep each deck together had been stiffened, but the vertical columns between decks had not.

Nevertheless, Wilson said, it was likely that loose underlying soil might be the crucial factor in the freeway collapse: "We had many freeway overpasses of similar design, and not all of them failed".

LOMA PRIETA EARTHQUAKE

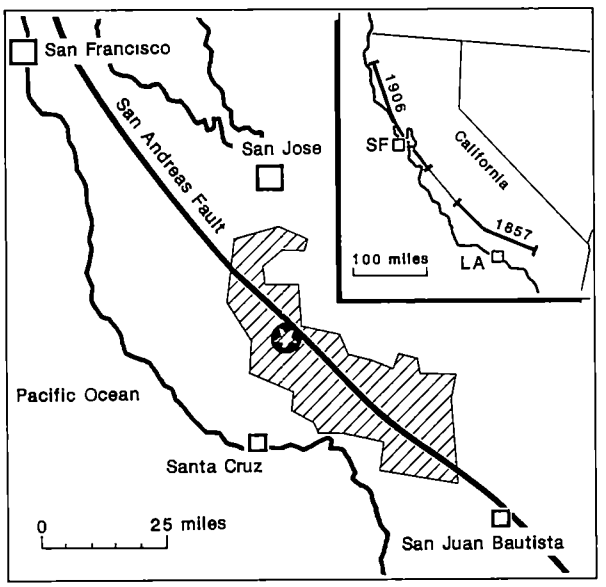
A successful prediction?

London

TWELVE hours after last week's earthquake in northern California, the United States Geological Survey (USGS) claimed that it had "forecast" the event in a report issued last year. Californians may find the value of this forecast debatable, but the close resemblance between the earthquake and the event foretold, not just by USGS but by many US seismologists over the past decade, encourages confidence that a practical understanding of earthquakes on the San Andreas Fault is within reach.

The earthquake, estimated at magnitude 6.9 (with about one-fifteenth the energy of the great San Francisco earthquake of 1906), had its epicentre in the mountains north-east of Santa Cruz, and has been named 'Loma Prieta' after a lookout station there. Its depth is thought to be 18 km, a little more than the characteristic 10–15 km depth of microearthquakes in the region.

So far, no unambiguous surface faulting has been identified, but very steep local terrain and thick brush makes it hard to distinguish true ruptures from superficial slumps and landslides. And from such a deep focus, the fault rupture may not have reached the surface at all.



The motion was primarily strike-slip (the two blocks of crust sliding past one another), typical of the San Andreas Fault, but there was also a small thrust component (one block being forced over another). The total slip is estimated to have been about 50 cm.

Since the main shock on Tuesday 17 October at 5:04 p.m. local time, thousands of aftershocks have spread out along the 50-km segment of the San Andreas Fault that ruptured. This segment, running from Pajaro Gap in the south, near San Juan Bautista, to Lexington Reservoir in the north, is the southernmost part of the 1906 rupture, which extended north for 450 km towards Cape Mendocino.

The southern stretch has attracted the attention of seismologists since at least 1983, when Al Lindh, of USGS in Menlo Park, California, identified a 45-km section north of San Juan Bautista as being likely to rupture in the following 20 years. For 150 km south of San Juan Bautista, the San Andreas Fault is creeping gradually, dissipating the strain that would cause an earthquake, but to the north and south of this 'central creeping segment', the fault is locked. The entire length of the 1906 rupture has been accumulating strain since 1906, making a future earthquake more likely.

Simple models suggest that when the strain relieved by a previous earthquake has been re-accumulated, the fault is ripe for another event of the same magnitude. The slip in the 1906 earthquake varied from about 5 metres near San Francisco to near zero at San Juan Bautista. The southernmost 90 km, the San Francisco Peninsula segment, slipped by only 1–3 metres, and at a continuing slip rate of 16 mm per year will recover its 1906 slip before the rest of the northern San Andreas.

Such reasoning led USGS to assign a 20 per cent probability to a magnitude 7 earthquake happening on the Peninsula segment within 30 years of 1988. But it put a probability of 30 per cent on an event rupturing only the southernmost 30 km, the Santa Cruz Mountains segment, with a predicted magnitude of 6.5. The Loma Prieta event falls between these two predictions.

The San Francisco Peninsula segment of the San Andreas Fault (main map), showing the epicentre (star) and the region of densely clustered aftershocks (shading) marking the Loma Prieta rupture. Inset shows the segments of the fault that ruptured in the great earthquakes of 1906 and 1857, separated by the 'central creeping segment'. SF, San Francisco; LA, Los Angeles

Some think that USGS was too conservative. Chris Scholz, of the Lamont-Doherty Geological Observatory in New York, estimated in 1985 that a 75-km length of the segment had slipped only 1–1.4 metres in 1906, rather than the 2.5 metres assumed by USGS, leading to an earthquake recurrence time of only 60–90 years, instead of 160 years. But despite all this uncertainty, there are reasons to think that earthquake prediction is getting better.

Most of the uncertainty in current predictions for the northern San Andreas derives from ignorance of what actually happened in 1906: estimates of the slip that occurred then vary by a factor of two. But modern geodetic instruments will give much more precise estimates of the slip that occurred last week. Moreover, the Loma Prieta event gives broad support to the idea that, at least on the San Andreas Fault, it is possible to identify 'characteristic earthquakes' — recurring ruptures of identifiable segments, with magnitudes and recurrence intervals that are, in principle, predictable.

The next important test of this hypothesis will be in the Parkfield segment, a 30-km section between the central creeping segment and the locked southern half of the fault. The Parkfield segment has experienced five moderate (magnitude 6) earthquakes since 1881, with an average recurrence time of 22 years. The most recent was in 1966, leading USGS to suggest a 90 per cent probability for a magnitude 6 earthquake on this segment in the next 30 years.

The Parkfield segment is being monitored for any precursory activity that might lead to a more specific prediction. In retrospect, there were seismic precursors to the Loma Prieta earthquake, in the form of two magnitude 5 earthquakes in June 1988 and August 1989. In each case, USGS issued a short-term (five-day) warning of enhanced probability of a larger earthquake, after which the probability reverted to its long-term value.

Similarly, there was a chance that the Loma Prieta earthquake itself could have triggered an earthquake on an adjacent segment of the San Andreas, but this threat has now receded. The largest aftershock recorded so far was of magnitude 5.2, 37 minutes after the main shock.

And what about the next one? Loma Prieta does not change the long-term probabilities for the region: there is still a probability of 50 per cent for a magnitude 7 earthquake in the Bay area over the next 30 years, and a 60 per cent probability for a magnitude 7.5–8 shock on the southern San Andreas over the same period.

But according to Scholz, the Loma Prieta rupture may have stopped 25 km short of the northern end of the region of reduced slip in 1906. An earthquake rupturing this remaining length of fault would be only of magnitude 6, but it would be much closer to the heavily populated Silicon Valley. **Laura Garwin**

Earthquake magnitudes

As earthquake sizes vary enormously, it is convenient to use a logarithmic scale. The well-known Richter magnitude is defined as the base-ten logarithm of the maximum seismic-wave amplitude in micrometres, recorded on a standard seismograph at 100 km from the earthquake epicentre. An increase in magnitude of one unit corresponds to a factor of 10 increase in wave amplitude, but a factor of 30 increase in earthquake energy. □

ANTARCTIC TREATY

France, Australia left in cold

Paris

AFTER ten days of intense deliberation, the fifteenth international Antarctic Convention Consultative Meeting came to an end in Paris last Friday still profoundly divided over the best way to safeguard the future of the continent. The 25 consultative parties and the 13 contracting parties to the Antarctic Treaty failed to achieve the unanimity required to adopt the Convention on the Regulation of Antarctic Mineral Resource Activities (CRAMRA).

CRAMRA was drafted at the initiative of New Zealand to fill a gap in the existing Antarctic Treaty regarding mineral exploration and exploitation, activities that are at present technically disallowed but not controlled. CRAMRA proposes to allow exploration, but only if stringent environmental rules are followed. Having signed the draft convention, France and Australia have since refused to ratify it, and want instead to turn Antarctica into a natural wilderness reserve and 'land of science', where all but approved scientific projects would be banned.

Two clear factions emerged in Paris, with New Zealand, the United States and Britain calling for the adoption of CRAMRA and Belgium, Italy, Greece and Austria supporting the Franco-Australian recommendation. The pro-CRAMRA lobby says sufficient environment safeguards exist within two annexes to the Antarctic Treaty and in the new convention.

At the same time, they say, the Franco-Australian proposals threaten to undermine the spirit of unanimity which has allowed the treaty to work well so far, while creating a parallel structure which, at the moment, lacks an appropriate administrative body.

But as a concession to the Franco-Australian axis, the Paris meeting recommended that a Special Antarctic Treaty Consultative Meeting be held in mid-1990 specifically to discuss the protection of the environment and dependent ecosystems. In a second recommendation, the section of CRAMRA devoted to environmental protection will also be the subject of a meeting next year.

Commander Jacques-Yves Cousteau, marine biologist and a campaigner for the idea of an Antarctic wilderness reserve, was visibly disappointed at the outcome of the meeting. "We haven't advanced one iota", he said, blaming "bureaucrats from foreign affairs ministries who think the Antarctic is their thing".

But some positive measures were adopted, including a new code of practice for the disposal of waste created by scientific missions — ironically one of the major sources of Antarctic pollution. A recommendation to control marine pollution and the creation of a new category of protected area — of 'general interest' — were also approved.

Cousteau nevertheless sees next year's special meeting as a small victory and says it will give France and Australia time to prepare a more cogent proposal. He denied that France and Australia have upset the previous unanimity that allowed CRAMRA to be drafted. On the contrary, he said, the new lack of unanimity is a sign that CRAMRA should be dropped. Speaking on Saturday, he claimed that CRAMRA is, in any case, premature: "no one is currently interested in commercial mineral exploration in the Antarctic". Meanwhile, he said, nations would serve the interests of Antarctica better by tackling real threats to the Antarctic environment, posed by uncontrolled shipping and aircraft in the area.

The sixteenth Consultative Meeting will be held in West Germany in 1991.

Peter Coles

ROCKEFELLER PRESIDENT

Baltimore accepts, amid controversy

Washington

THE Rockefeller University announced last week that David Baltimore, director of the Whitehead Institute in Cambridge, Massachusetts, since it was founded in 1982, will replace Joshua Lederberg as president of the university on 1 July 1990, when Lederberg retires. Baltimore, a Rockefeller alumnus, says his plans include "increasing the teaching role of the university, . . . bringing the Rockefeller community more sense of common purpose, increasing the role of younger scientists, and positioning the university to lead the way in understanding the nervous system".

Rockefeller's offer to Baltimore at first created controversy. Members of the faculty protested that Baltimore's links with the highly publicized misconduct allegations arising from a paper that he co-authored would damage the university's reputation. But Baltimore is said to have won over the opposition at a discussion with the faculty.

Christine McGourty

US SURGEON-GENERAL

First woman nominated

Washington

THE deputy director of the National Institute of Child Health and Human Development, Antonia Novello, is likely to be the next surgeon-general of the United States, replacing the forthright C. Everett Koop who left earlier this year. Selection of a replacement has been slow, it is said because of the importance of finding a candidate who supported President Bush in his opposition to abortion.

Although her nomination, which would have to be confirmed by Congress, has not been formally announced by the Bush administration, Novello, a specialist in paediatric AIDS and known for her support of women's issues, is said to be the leading candidate.

Christine McGourty

AIDS

European trials of AZT to continue

Paris

AN Anglo-French placebo-controlled clinical trial of AZT in people infected with HIV (human immunodeficiency virus) but showing no symptoms of AIDS proper is to continue despite the short-term positive results that led a similar trial in the United States to be abandoned (see *Nature* 340, 581; 1989) The trial, called Concorde 1, is jointly sponsored by the British Medical Research Council and the French Institut National de la Santé et de la Recherche Medicale (INSERM).

After the apparent success in the US trial of AZT in slowing progression to AIDS and advanced AIDS-related complex in individuals with a T4 cell-count of less than 500, the US National Institute of Allergies and Infectious Diseases (NIAID) ordered a halt to the trial. Since then, AZT (or Zidovudine in France), has been approved by the US Food and Drug Administration for use with individuals in an early stage of HIV infection.

After discussions with NIAID officials, the Data and Safety Monitoring Committee (DSMC) of the Concorde 1 study has decided that "the scientific data now available do not allow strict recommendations to be made about Zidovudine treatment of asymptomatic HIV positive people based on their CD4 lymphocyte counts. This applies equally to people in trials and in clinical practice."

According to Professor Jean Dormont, of the INSERM immunopathology unit at Clamart near Paris, the US data are not in question, but allow no conclusions about AZT in asymptomatic HIV-infected individuals. "The DSMC has advised us to continue the trial in order to try to obtain longer-term results. But we will leave it to each participating centre to decide, as a matter of conscience, whether it is appropriate to put an individual onto AZT with a T4 count of 500 or not".

Peter Coles

COLD FUSION

Noncommittal outcome

Washington

THE title "Anomalous effects in deuterated metals" hardly disguised the fact that a closed meeting in Washington last week was about cold fusion. The three-day workshop (16–18 October), organized by the National Science Foundation (NSF) and the Electric Power Research Institute (EPRI), an industry-based technology development association, brought together a remarkable collection of those who have seen "anomalous effects", including Stanley Pons and Martin Fleischmann. Also present were some sceptics, notably Nate Lewis of the California Institute of Technology. Getting these people together was no easy feat: at least two outspoken critics refused to attend because they saw little in the meeting but a parade of dubious and mostly well-known evidence for cold fusion, whereas one believer had to be persuaded that the workshop was not stacked with sceptics before he agreed to attend. And, contrary to usual NSF practice, the workshop was closed to the press.

According to Paul Werbos, programme director for Emerging Technologies in NSF's division of Electrical and Communication Systems, the workshop was meant to help NSF deal with a steady stream of grant applications for cold-fusion experiments. Werbos consulted an NSF colleague on leave from EPRI, which has been supporting experiments at Texas A&M University, and the idea was born of a jointly organized meeting, co-chaired by John Appleby of Texas A&M and Paul Chu of the University of Houston, Texas.

Although some new data were presented at the meeting, a final statement issued to the press by Appleby gave no details, observing only that anomalous heating "appears to be real in many cases" and that there was reason to believe that the appearance of tritium in some electrolytic cells "is not an artefact". But others who attended the sessions said that no consensus was reached on any of the experimental results. No one denied that the detection of tritium was genuine, but several remained unconvinced that contamination had not been ruled out. And the claims of excess heat were as controversial as ever, with some saying that the calorimetry appeared to carefully done, while others decried a lack of controls and reproducibility.

Werbos emphasized that the purpose of the meeting was not to pass judgment but to decide what research ought to be done. Both sides in the debate seem to accept that the heat measurements will probably not prove convincing one way or the other, and that the presence or absence of nuclear products is the crucial evidence. To this end, Edward Teller of Lawrence Livermore Laboratory suggested that partial replacement of palladium with uranium-235, which accepts neutrons readily, would help to determine if some kind of neutron transfer initiated by deuterium was at work.

In about a month, the proceedings of the NSF/EPRI workshop will be released, along with some recommendations for further research. This report should appear at about the same time as the conclusions of the Department of Energy's (DoE) special panel on cold fusion, a preliminary version of which recommended against putting any money into the area (see *Nature* **340**, 174; 1989).

Thomas Schneider of EPRI did not accept the idea, put about by critics, that the purpose of last week's meeting was to provide a counterweight to the anticipated negative verdict of DoE's "killer commission", as John Bockris of Texas A&M has dubbed it.

But if the aim was to find some common ground between believers and critics, the workshop had little success. Those who seem able to get anomalous results see a need for further research, and argue that one should not dwell on "negative" results because in those experiments, evidently, the conditions are not quite right for cold fusion to work. Critics, on the other hand, maintain that if you are allowed to keep positive results and throw away the rest you can never be proved wrong: it becomes, as one sceptic put it, religion, not science.

David Lindley

GENOME MAPPING

Speak softly or carry a big stick

Washington

FUELLING the debate over how to coordinate and finance international efforts to sequence the human genome, James Watson, director of the National Institutes of Health Center for Genome Research, said last week that the United States should ensure that other countries support basic research by threatening to restrict access to its data. Testifying at a hearing of the House of Representatives subcommittee on international scientific cooperation, Watson declared that "America has been subsidizing the rest of the world for too long in science and it's time that [others] came in".

The subcommittee, set up three years ago to examine financing for 'big science' projects, is scrutinizing the $3,000-million human genome project because of fears that the United States might end up subsidizing foreign biotechnology industries. Watson confirmed these fears, saying it was possible that the United States would do all the basic research while others would focus on the commercial applications.

Although the United States could map and sequence the human genome alone, said Watson, "it makes sense to reduce the cost to the American public by some form of sharing". And a political reason for collaboration, Watson added, was that if the United States were to tackle the project alone, the prospect of one country claiming all rights to the data might put the rest of the world "ill at ease".

But instead of a multitude of bilateral agreements — such as the agreement between the UK Medical Research Council in Cambridge and Washington University Medical School in St Louis to sequence the nematode — Watson endorsed HUGO (the Human Genome Organization) as the vehicle to facilitate international collaborations. Although HUGO has been accused of inactivity, leading some to argue against contributing to it, Watson says supporting it will save the United States "a great deal". If other countries did not participate, he said, he would hold on to the US data "for quite a bit of time".

HUGO treasurer George Cahill, of the Howard Hughes Medical Institute (HHMI), said Watson was "playing hardball" and that he would favour "a more soft and more diplomatic" approach to encourage international genome mapping efforts. More countries want to join HUGO, he said, and will do so when it has "more stability and funding". Cahill says HUGO may begin to move more quickly within the next few weeks after it becomes a US corporation, which would allow it to receive a $1 million gift that HHMI is considering. After that, "we could really have some clout and could get moving", says Cahill.

WORLD PSYCHIATRY

Readmission with strings

Athens

THE World Psychiatric Association (WPA) last week voted to readmit the Soviet All-Union Society of Psychiatrists and Narcologists to conditional membership. But despite the overwhelming vote in favour (291 for, 45 against and 19 abstentions), the readmission was not smooth.

The vote was plainly a consequence of tough bargaining. During the meeting, the All-Union society read out a statement acknowledging that there had previously been psychiatric abuses for non-medical, including political, reasons.

Western human rights campaigners, notably the International Association on the Political Use of Psychiatry, described as largely cosmetic the reforms introduced in the Soviet Union in the past five years, when patients' rights to appeal against involuntary hospitalization have been strengthened, the 'special' psychiatric hospitals have been transferred from the prison service to the Ministry of Health and open discussion of Jung and Freud has been allowed.

In particular, the British Royal College of Psychiatrists was still, last week, seeking a formal retraction of the Soviet charge of slander, while WPA itself was criticized for having failed to put forward an application for membership from the Independent Psychiatric Association, the unofficial alternative to the All-Union society.

In the event, the unofficial body was granted unconditional membership, but the All-Union association will be monitored continuously by the WPA review committee; it was warned, last week, that the continuation of abuses may lead to another expulsion. The Bulgarian and Czechoslovak associations returned almost unnoticed to the fold, but the Cuban association, whose government has little time for *perestroika*, did not apply for renewed membership.

The readmission of the Soviet association to the club was the decision of the WPA General Assembly, which spent much of last week wrestling with ethical issues. Should the suicide of patients be considered 'rational'? What are the rights of third parties providing funds, governments or insurance companies, in the therapeutic process? And what if a genetic basis is established for psychiatric illness? Sir Martin Roth of the Cambridge Clinical School, argued in his closing address that the benefits of such a facility would be offset, at least in part, by the dangers of abuse. Roth particularly emphasized that awareness of the genetic background of psychiatric illness should not lead to prejudice against the carriers of these genes.

SAFETY TESTING

Death-knell for LD50?

London

BELIEVING that a more humane alternative now exists, the European Commission has decided to put a stop to the assessment of the toxicity of chemicals by the present LD50 (lethal dose — 50 per cent) criterion, in the determination of which large numbers of animals are killed. The criterion is at present given statutory backing by European legislation dealing with the safety of medicines and the introduction of new chemicals into the environment.

After a two-day meeting in Brussels, a senior Commission spokesman said the LD50 system, which has been used since the 1920s, should be replaced, after a £500,000 validation programme, by a "fixed-dose" criterion. Dr Michael Balls, from the University of Nottingham Medical School, said the meeting had ended in a mood of great optimism. He applauded the Commission's decision and said that other countries in the Organization for Economic Cooperation and Development (OECD) now using the LD50 criterion should adopt the proposed new system.

LD-50 trials, in which varied doses of chemicals are given to groups of animals so as to determine what dose kills half of a group, have long been condemned by animal rights groups. The criterion was adopted in 1985 by the OECD countries, but in 1987 the guidelines were changed to reduce the number of animals needed, although the principle remained the same.

Balls, who is also a trustee of the Fund for the Replacement of Animals in Medical Experiments (FRAME), says that the more efficient fixed dose formula would reduce the use of experimental animals. "A good toxicologist can administer a fixed dose, depending on what is known about the drug, and judge the toxicity of a chemical by the animal's response", he said.

The validation studies on the fixed-dose criterion, initiated by the UK Home Office and Department of Health with the European Commission, have been carried out in 31 laboratories in Europe, Japan and the United States. At the Brussels meeting, the Commission was presented with results demonstrating the feasibility of the fixed dose procedure. According to Balls, a senior Commission spokesman said he was "convinced" that the method would work and that the Commission was "determined" to see it put into practice.

The Commission must now persuade the OECD countries outside Europe to accept the new guidelines; Sweden and Switzerland gave their approval at the meeting. "The European Commission has thrown down the gauntlet to the US and Japan". Balls added: "It is no longer a question of science, it is now up to the politicians".

INDIAN SCIENCE

Laboratory directors fight bureaucrats

New Delhi

A NEW ruling by the Council of Scientific and Industrial Research (CSIR) requiring the directors of its approximately 40 laboratories to quit after six years of service has thrown the agency, India's main research organization, into a crisis. One director has resigned, some are planning to take CSIR to court and most are rebelling against their director general, A. P. Mitra.

The provocation is a letter from CSIR headquarters in New Delhi informing the directors that under revised rules they have the option, after a non-renewable term of six years, of remaining as 'director-level' scientists or moving to CSIR headquarters.

Implementation of the rule comes two years after it was recommended by a review committee; CSIR laboratory directors protested at the time and hoped the new rule would not be put into practice. But their protests seem to have been in vain.

Enforcement of the six-year rule would require 20 of the 40 directors to leave their posts by next year. P. K. Ray, who resigned a $60,000-a-year US job to become director of the industrial toxicology research centre, is one of many who have been asked to sign a new contract. So far only one has complied.

Some argue that the new letter is in breach of the previous contract, which did not specify a fixed tenure. Three directors are planning to fight CSIR in court and six are hoping to return to institutions which they left to join CSIR. P. K. Jena, director of the Regional Research Laboratory (RRL) in Bhubaneswar, resigned in disgust, and J. N. Barua, director of RRL in Jorhat, has refused to vacate his post although he has completed six years.

Pushpa Bhargava, director of the Centre for Cellular and Molecular Biology, has asked Prime Minister Rajiv Gandhi to intervene but with general elections due in November, Gandhi has little time to defuse what could be the biggest crisis in CSIR's 40-year history.

The directors say the crisis could have been averted had Mitra consulted them beforehand. He is also accused of favouritism in giving 'courtesy extensions' to five directors who have completed six years, while asking others to comply with the rule. But Mitra seems unperturbed. He has avoided meeting the directors or the press.

GENETIC ENGINEERING

New advisory board approved

Washington

LOUIS Sullivan, Secretary of the Department of Health and Human Services, surprised the biotechnology research community two weeks ago with the announcement that he was about to give his formal approval now to the establishment of a new government advisory body on biotechnology, to be called the National Biotechnology Policy Board (NBPB). It will concentrate on technology transfer from university and federal research laboratories and the competitiveness of the US biotechnology industry.

Congress directed the National Institutes of Health (NIH) to establish the board last year and wanted to see its first report in January 1990, but members of the board have not yet been selected from a list of about 80 candidates. Responsibility for establishing it lies with the NIH Office of Recombinant DNA Activities, whose director, Nelson Wivel, says that it might be in place early next year, now that Sullivan is ready to sign the charter.

The board will consist of representatives from all the federal agencies that support or regulate biotechnology research, four university researchers, four representatives of the biotechnology industry, two members from state biotechnology development programmes, one member of a charitable institute and a bioethicist.

The Congressional Bioethics Board (CEB) was charged with reviewing reports from the NBPB, but is unlikely now to do so: after a short and controversial life, the CEB was dissolved on 1 October (see *Nature* **341**, 6; 7 September 1989). It made no progress on any of its planned studies, the board members spending most of their time arguing over the selection of members for its advisory committee, with a candidate's views on the abortion issue being the deciding factor. Bob Cook Degan, former executive director of the board, says that for the moment he thinks the board is "dead permanently. It's certainly dead transiently".

Some of the NBPB's responsibilities, such as its mandate to "enhance basic and applied research", might overlap with those of the existing Biotechnology Science Coordinating Committee (BSCC), yet another advisory body in this field which has likewise not been without its share of controversy. The president's Office of Science and Technology Policy set up the BSCC in 1985 to coordinate the regulation of biotechnology across all the federal agencies. Last year it became bogged down in a dispute between the Environmental Protection Agency (EPA) and the Food and Drug Administration over whether the EPA should regulate non-coding as well as coding genetic sequences. An EPA rule on the regulation of genetically manipulated microorganisms was delayed. Last week, Bill Reilly, the EPA administrator, said it would be ready early next year.

But a report published two weeks ago, written by Sidney Shapiro of the University of Kansas for the Administrative Conference of the United States, a Washington-based think-tank, is highly critical of the BSCC and recommends that it should be dismantled. BSSC's chairman, John Moore, who is also a deputy director at the National Science Foundation, says the committee is at present discussing how the new NBPB will affect its role. But he says that although some of the criticisms might have been valid in the past the BSCC is "on a pretty good keel right now".

Shapiro says that gaps still exist in the regulation of genetically manipulated organisms and that the existing biotechnology regulation framework "is a prescription for inconsistent regulation and litigation". He recommends that a new committee be set up with a broader membership and permission to consider a wider range of issues. It should be more accessible to the public. Margaret Mellon of the National Wildlife Federation says that Shapiro's criticisms are not out of date, and that the burden lies with the BSCC to prove that it is not a "creature of industry". **Christine McGourty**

Britain regulates organism release

London

REGULATIONS put before the British Parliament two weeks ago will make it compulsory, from 1 November, to notify the government's Health and Safety Executive (HSE) of the use or deliberate release of genetically manipulated organisms. HSE must be given 90 days' notice to allow time for a safety assessment of any proposed activity.

The new scheme, first put forward in 1987 by the Health and Safety Commission (HSC) and its Advisory Committee on Genetic Manipulation (ACGM), replaces the present voluntary system of notification. Richard Clifton, chief administrator of the executive's medical division, said the changes were necessary to keep up with advances in the field. He said the HSE had adopted a "pragmatic" and "step by step" approach to safety regulation.

The new provisions also require that laboratories assess the risks involved using a method approved by the HSE and that a genetic manipulation safety committee be set up at each centre undertaking such work. The regulations revise the definition of 'genetic manipulation' to include the incorporation of heritable material into an organism either directly or indirectly, using vector systems, and also provide for simplified annual retrospective notifications for low-risk activities.

In due course, the regulations now imminent in Britain may be overtaken by impending legislation. The European Commission has yet to agree the form of a directive, which may well be more stringent, while there is every likelihood that the British government's expected bill on environmental matters will also deal with the release of engineered organisms.

Microinjection patent granted

Washington

THE US patent for microinjection, the most widely used technique for creating transgenic animals, was granted this month to Thomas Wagner of Ohio University and Peter Hoppe of Jackson Laboratories in Bar Harbor, Maine. The patent is not restricted to any particular species of mammal or the transfer of any specific gene.

Wagner and Hoppe have assigned the patent to Ohio University, which has licensed the commercial rights to the small biotechnology company DNX Inc. University researchers can continue to use the technique free of charge, but biotechnology companies that wish to make use of microinjection for research purposes will have to pay an annual licence fee. Companies wanting to use the technique to create commercial products will be able to obtain an exclusive or a non-exclusive licence, which will be negotiated on a case-by-case basis.

Holtzman estimates that about 35 companies are now using microinjection; its applications include the development of the multi-million dollar-clot-dissolving drug TPA (tissue plasminogen activator), and of Factor V111, the blood-clotting protein used to treat one form of haemophilia. It was also used to develop the 'oncomouse', the first patented transgenic animal, which is being sold by Dupont and is expected to be useful in the testing of drugs against cancer. Wagner has assigned his royalties to the university's Edison Animal Technology Center.

Wagner and Hoppe filed for the patent in 1981, shortly before they published an account of the research in which they were the first to achieve, in a single experiment, the introduction of a foreign gene into a different species of mammal and its transmission through the germ line into a second generation of animals. Although microinjection was being used by other researchers at the same time, no competing patents are thought to have been filed and Stephen Holtzman, Ohio University's vice-president for corporate development, says the patent is "strong and enforceable". Ohio University has also filed for the patent in Europe. Christine McGourty

Conflict of interest

SIR—There was one omission in your leading article on conflict of interest (*Nature* **340**, 664; 1989). This is the situation when an academic department, or individual, receives both governmental and industrial funding. The conflict arises not from individual inclinations towards the source of the funding, but rather from the source of the funding itself. Benefits, if any, from research supported by the government should go back to the ultimate source of the funding, the taxpayer. On the other hand, benefits from research supported by industry end up as profits to shareholders.

The conflict arises because in many cases the benefits are not the same. I think we would all agree that industrial money becomes available to an academic department or individual because of a good track record in the fruition of the research which in most cases was supported by government funds. In other words, industry buys rather cheaply the fruits of government funding. Shareholders thus get a pay-off from this latter work, while taxpayers pay twice, once for supporting the original research and again in paying for the results of the research in the form of profits to the company.

One remedy is to cut off all government funding to departments or individuals who obtain industrial funding. This move will not, however, solve the main problem. In our capitalistic society, the only solution is for a portion of the profits resulting from research supported by both funding sources to be ploughed back by industry, either into general government research funds or back to the taxpayer in the form of payback into general government funds. Equity demands that research supported by government supposedly to benefit all should not be used to benefit only a few. Just because industry is the only source, for example, of mass-produced drugs does not mean that industry should not pay a fair share of the taxpayer's part of the cost of the research done to obtain these drugs.

PHILIP SIEKEVITZ

Rockefeller University, New York, New York 10021-6399, USA

SIR—Your sensible leading article (*Nature* **340**, 664; 1989) missed one important point. Rules about conflict of interest are designed to eliminate unfair personal gain, or at the least to minimize its likelihood. In the leading article and in most other discussions of conflict of interest, personal gain is assumed to be of the financial or other material variety.

Everyone is to a greater or lesser degree interested in material rewards But some scientists, perhaps particularly those who are the brightest and most ambitious, are likely to value academic reputation and prestige at least as highly as financial gain. Scientists may therefore be susceptible to the temptation to act in ways that may enhance their reputation or may damage the reputations and research opportunities of academic competitors. The obvious situation in which this may occur is in peer review of papers or grant applications.

Conflict of interest rules that concentrate purely on material issues are likely to miss many situations in which scientists can take unfair advantage. Guidelines should also require scientists to be explicit about purely academic conflicts of interest. I suspect that many of the complaints about unfair refereeing would disappear if this were the case.

Alkaline rain?

SIR—Søren Peter Lauritz Sørensen (1868–1939) must be turning in his grave in Copenhagen. As every student of introductory chemistry knows, Sørensen (in 1909) defined pH as $-\log a_{H+}$, and therefore, as acidity increases, the pH value decreases. Although David Swinbanks' report on acid rain in Japan (*Nature* **340**, 671; 1989) clearly and consistently recognizes this fact, the title "China blamed for high [*sic*] pH," apparently written by someone other than the author, is incorrect and does not make sense.

GEORGE B. KAUFFMAN

Department of Chemistry, California State University, Fresno, Fresno, California 93740, USA

To boldly go . . .

SIR—The article by Andrew Tudor on the image of scientists in horror films (*Nature* **340**, 589; 1989), was amusing and interesting. I'd like to add a note about more recent films in the genre of science fiction.

Lately there has been a reaction against the *Frankenstein* image. Films such as *Altered States* and *Brain Storm* have begun taking a rebellious, almost faustian tack, in which the scientist is depicted as an adventurer, a hero. Even if his daring leads to pain, that is nobody's business as long as the only one hurt is himself. Since biblical times there have been messages decrying hubris, and *Frankenstein* does warn us to beware unforeseen consequences. Still, it's good to hear the other side as well.

The best recent example of these two views in conflict were two popular films in the *Star Trek* series. In *The Wrath of Khan*, the son and former wife of Captain Kirk have invented a 'Genesis Device' which causes life-bearing worlds to coalesce out of a dusty nebula. This unabashedly faustian film utterly rejects the biblical-Frankenstein code, depicting this creative act as a glorious one, filled with hope and pride.

But old habits reassert themselves in the sequel, *Search for Spock*. The genesis world is flawed, falling apart just as Frankenstein's monster did. Indeed, the 'creator' is killed by his creation. The lesson, once again, is that man should never try to assert the prerogatives of heaven, and what was noble in the earlier film is now portrayed as horrible.

All this may be dismissed as irrelevant, but it is in popular media that public attitudes — and our children's — are formed Scientists may stay aloof, but that will surely leave myth-making in the hands of ignorant men.

Plagiarism

SIR—The view of the National Institutes of Health Investigating Committee as reported in *Nature* (**340**, 173; 1989) is surely mistaken. Plagiarism is not "at least as serious a misconduct in science as outright fabrication of experimental data". Both fabrication and plagiarism are dishonest and abuse the peer-review system, but fabrication is harmful for science in a way that plagiarism is not. Fabricated data can be detected and corrected (if at all — consider the difficulties in ecological research) only at great cost, whereas plagiarism is often a matter of public record. When undetected, fabricated data are actively misleading, whereas plagiarism merely introduces redundancy. Neither is excusable, but they are not equally damaging to science.

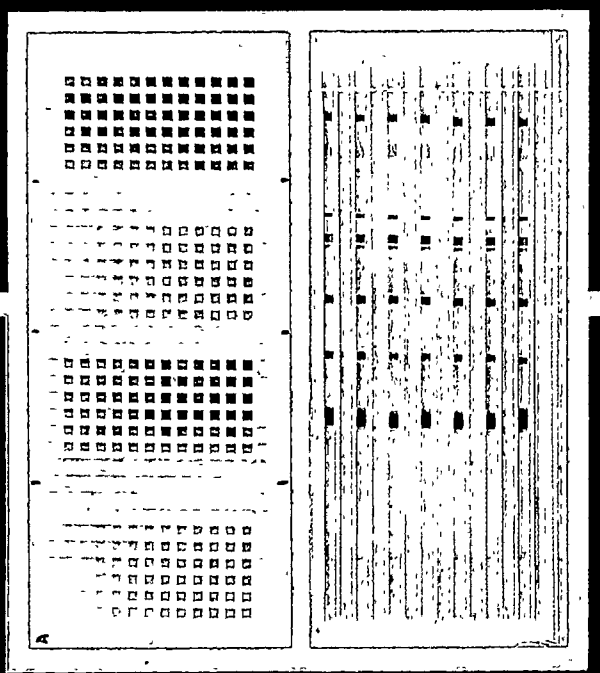
Mirror in space



SIR—In response to the suggestion of putting a large lightweight mirror in space between Sun and Earth in order to reduce the solar radiations on our planet (*Nature* **340**, 603; 1989), let me point out that the energy requirement for such an operation would be substantially diminished (two orders of magnitude, at least) if we could take the Moon as a starting point, that is, if we managed to build the mirror in the Moon with lunar material and subsequently bring it to the appropriate point.

Unlimited affinity for FPLC®

Pharmacia LKB, established leader in the field of affinity gels, introduces yet another first: N-hydroxysuccinimide (NHS)-activated Superose®, for high performance affinity chromatography with FPLC.

The addition of this new gel expands our existing range of prepacked columns for affinity chromatography - Protein G Superose, Protein A Superose and Chelating Superose - and gives unmatched versatility for ligand immobilisation. Now, with NHS-activated Superose you can obtain a high performance affinity media to suit your particular application, for example separation of receptors, antibodies, enzymes and hormones.

Our affinity gels show low non-specific interaction and negligible ligand leakage. They are based on Superose 12, the well-known high performance agarose hydrophilic matrix (13 µm), with high chemical stability over a broad pH range.

Prepacked in glass columns, Pharmacia LKB affinity gels are easy to use. They give reproducible results with high recovery and purity, and when used with FPLC System introduce a number of unique, automated features such as: coupling of ligands to NHS-activated Superose, column regeneration, pH adjustment of eluted fractions, column/buffer switching and method optimisation.

Finally, what could complement the affinity package better than FPLCmanager. The software designed to accelerate and enhance the evaluation and reporting capability of automated FPLC.

High performance affinity chromatography with FPLC System. Contact a representative today and see for yourself how unlimited your affinity separations can be.

We help you manage biomolecules.

Life Science — Science for a Better Life

With over 20 years in progress, the field of Life Science is emerging today from adolescence into full-bodied adulthood. As researchers gain valuable experience, they are moving ever closer to unlocking the secret mysteries of nature.

Mitsubishi Kasei is playing a leading role in this challenging pursuit. At its main Research Center, the Mitsubishi Kasei Institute of Life Sciences and Plantech Research Institute, biotechnology research is making important strides across the entire spectrum of study. Through persistent dedication, we're probing the way to a better and richer life for mankind tomorrow.

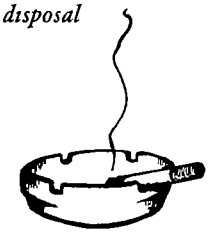
Q: Why do we have radioactive waste anyway?

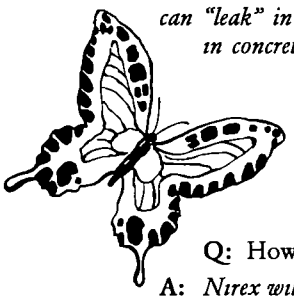
A: *All industries produce waste. The nuclear industry is no different. If we want the benefits of nuclear electricity and nuclear medicine we have to accept the waste. But even if we could stop using nuclear technology, waste that already exists would still have to be safely disposed of.*



Q: What sort of waste is UK Nirex Ltd. responsible for?

A: *Only low and medium level radioactive waste. Low level waste has been routinely disposed of for 30 years and medium level waste has been stored.*

Tough questions. Honest answers.



Q: Why isn't radioactive waste stored in the place it's produced?

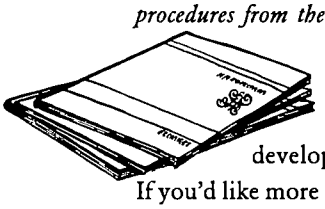
A: *Many reasons. In particular it will be less safe in the long term to have stores dotted around the country close to man and the environment than to have one high quality disposal site protected by hundreds of feet of rock.*

Q: What is the likelihood of radiation escaping and harming people?

A: *The chances of anyone being harmed are less than one in a million, which is about the same as the risk involved in smoking just one cigarette in a year. Nothing can "leak" in the normal sense, as all the waste in a disposal centre will be set in concrete.*

Q: What's to stop radioactivity leaking into the environment?

A: *Multiple barriers are placed between the waste and the environment. These include steel drums, layers of concrete and the carefully chosen surrounding rocks, which will contain the waste for many thousands of years.*



Q: How will wildlife and plants be affected near the site?

A: *Nirex will take great care to make sure that the environment is safe and the site will be carefully surveyed to protect any rare or unusual species.*

Q: Who is responsible for making sure the highest safety standards are upheld?

A: *Ultimate responsibility lies with the Secretary of State for the Environment along with the Secretaries of State for Scotland and Wales. UK Nirex is also monitored by the Department of the Environment, the Ministry of Agriculture Fisheries and Food and the Nuclear Installations Inspectorate, as well as receiving advice on procedures from the National Radiological Protection Board.*

UK Nirex Ltd., a company owned by the Central Electricity Generating Board, British Nuclear Fuels plc, the UK Atomic Energy Authority and the South of Scotland Electricity Board, is to develop and build a deep underground disposal centre for radioactive waste. If you'd like more answers on radioactive waste disposal just phone our Information Line on 0235 833009.

SAFE FOR THE FUTURE

Reader Service No.8

The future of research in medicine

John Galloway

The government intends to reform Britain's National Health Service. Medical research — much of which is supported by charities — will suffer if the government does not think again.

No one with any sense disagrees with the British government's aim to make the country's National Health Service (NHS) more effective. It is ironic therefore that its proposals for re-organization laid out in the White Paper *Working for Patients*, a statement of the government's intentions published earlier this year, may destroy the principal means by which that aim can be achieved. Good quality information and its efficient dissemination are the routes both to better services and to greater value for money. Research is the activity that produces new and better information; and research is probably what is at greatest risk from the government's plans.

Role of charities

The White Paper is sparing — to say the least — in its consideration of science. The paragraph that starts so promisingly on page 38 ("The Government is firmly committed to maintaining the quality of medical education and research . . .") provides no evidence that it understands the critical part played by medical research in the evolution of the NHS or of the effect that reform will have. Nor does it appear to appreciate the extraordinary role in the development of medical practice — prevention, treatment and support — played by medical research charities and trusts in partnership with the health service. Indeed Working Paper 2 (paragraph 4.12) is less than reassuring on this final point — "Medical charities and foundations expect the NHS to fund in full or in part the service support of research they carry out". There is no hint whether the future health service will continue its half of the partnership and provide this service support or not.

Also on page 38, there is the promise "to discuss with Regional Health Authorities (RHAs) how best to ensure that other costs associated with training and research are also met without putting one hospital at an unfair disadvantage by comparison with another". Again, there is no clue as to whether considerations of fairness will apply to the health service's charitable partners in many crucial medical areas.

It is a curious feature of British medical research (almost certainly a unique one) that as much research in Britain's universities, medical schools, hospitals and research institutes is financed by independent charities and trusts as by the government. Table 1 brings a number of features of the British system into sharp relief. Spending by the members of the Association of British Pharmaceutical Industries (ABPI) is comparable with the total expenditure of the Advisory Board to the Research Councils (ABRC) or that of the University Funding Council (UFC). Presumably this is an indication of the importance placed on research by the pharmaceutical industry — or the relative lack of it by the government.

More to the point, total spending on medical research from government sources is less than 1 per cent of the cost of running the NHS. This figure contrasts with the funds provided by the members of the ABPI, who spent an estimated £743 million on research and development during 1988 (close to 15 per cent of the value of their sales of £4.8 billion in the same year). The greater part of government spending on medical research is covered by the £150 million or so grant-in-aid to the Medical Research Council (MRC). This figure is now almost exactly matched by the members, and the handful of affiliate members, of the Association of Medical Research Charities (AMRC) (Table 2 — see over).

Such a large contribution from charities appears to have no parallel in any other research arena. Nor does any other country comparable with Britain in its engagement in medical research depend to such an overwhelming extent on charitable support. This support could be threatened by present government plans in its intended reforms of both the universities and the NHS. The spectre of the necessity of paying general university overheads has appeared (and remains) for those charities supporting university research through grants. The prospect is a grim one for charities and scientists alike; the level of medical research supported through grants from the charities could be halved at a stroke The outlook within the health service, as opposed to the university and polytechnic systems, may be even worse. At least within university settings the framework for research will remain. Within the reformed health service it is unclear that it will.

Most of the charities are 'mission orientated'. Their interest is in a single disease, cystic fibrosis or muscular dystrophy for example, or in a group of closely related diseases such as the leukaemias or the cancers generally. Often these charities are the only source of money for research into their chosen disease, or at the very least the principal source (although there are notable exceptions; whereas some diseases enjoy great popularity with the public, others do not, sexually transmitted diseases or psychiatric illness for example). There are few charities or trusts with a broader, more philanthropic interest in medical research (the Wellcome Trust is the best example).

Cancer research

Cancer research is the clearest example of charitable support of research in medicine (Table 3). Government sources account for only about 10 per cent of the £100 million a year spent on such research, currently about £2.5 million through the Department of Health itself and another £9 million by the MRC. The latter figure has fallen steadily, from 11 per cent in 1985–86 to about 7 per cent of the MRC's total research expenditure in the present

TABLE 1 Research funding in Britain, 1989

Members of the Association of British Pharmaceutical Industries	743
Industrial and commercial spending in universities and polytechnics	260

*Total spending by the DES through the University Funding Council and the Polytechnic and Colleges Funding Council is £6,000 million.

†National Radiological Protection Board, National Institute of Biological Standards and Controls, Public Health Laboratory Service, Central Blood Laboratory Service

year. The other 90 per cent is provided by charities — the Imperial Cancer Research Fund (ICRF), the Cancer Research Campaign (CRC), the Leukaemia Research Fund (LRF), all large national charities, together with numerous smaller charities, many of them locally organized and supporting research in particular geographical areas or even limiting spending to individual hospitals.

Even these figures, telling as they are, hardly reveal the extent to which, in Britain, responsibility for cancer research and the development of clinical oncology as an arm of cancer medicine lies with the charities and depends on the initiatives they take. The Cancer Research Campaign has established and finances academic departments of clinical oncology in the Universities of Glasgow, Manchester, Liverpool, Cambridge, Southampton and London (at the Institute of Cancer Research, allied to the Royal Marsden Hospital). In Nottingham a new department of clinical oncology is being set up by the CRC collaborating with the Regional and District Health Authorities. Clinical Oncology Units have been established by the ICRF at St Bartholomew's Medical College, London, and the Universities of Edinburgh and Oxford. Indeed, only one chair of clinical oncology in Britain is not the result of an initiative by one of the biggest cancer research charities and its endowment by private subscription. The Leukaemia Research Fund has endowed chairs of haematological medicine in Cambridge and haematological oncology at the Royal Postgraduate Medical School. The record of the British Heart Foundation is even more impressive with 14 endowed chairs of cardiology, and subjects closely allied to it, distributed throughout Britain, and six personal chairs.

These few examples are not, nor are intended to be, exhaustive of the degree to which the charities provide one vertex of a medical care and research partnership triangle — the other two vertices being the health service and the medical schools. But they provide the clearest instances.

Specialist treatment

The key characteristic of most medical research charities is that the basic research they support should be turned into genuine benefits for those suffering from the particular disease, and for their families. The development and support of specialist treatment units is a large part of the activities of many charities. The Cystic Fibrosis Research Trust (CFRT) is a good example. The trust's main activity is research, into the nature of the faulty CF gene and into heart–lung transplants for example. Recognizing that those with the disease fare better in specialist CF centres, the CFRT finances clinical fellows, in the shape of registrars reading for medical degrees at CF treatment centres (14 at the last count).

Specialist centres are often supra-regional, but might equally be placed in district hospitals. There are Muscular Dystrophy Group medical centres at Newcastle and Hammersmith that have received considerable support from the charity for 12 and 15 years respectively. The two centres have established excellent reputations and patients are referred to them from most of Britain. The centres carry out research but also offer clinical diagnosis and management. Substantial and long-term commitment from a charity to a centre within an existing department has enabled the development of a particular area of clinical research and care.

These last examples illustrate one simple way in which the government's attitude to the health service is damaging research and could damage it further. An immediate consequence of chronic underfunding is the diversion of research funds to routine clinical care which must then result in a decline in the level of clinical, as well as biomedical, research. Many of the medical research charities expected that their experimental initiatives in turning research into treatment would in time become part of the health service routine. This is now not happening. Charities are, of necessity, shouldering the responsibility for the long-term provision of treatment. Indeed, the government would probably like to turn the screw even further and put pressure on charities to take over responsibility for government initiatives, cancer prevention for example, as was clear from informal discussions between the CRC and the junior health minister last year.

TABLE 2 Expenditure on research by the Medical Research Council and Association of Medical Research Charities

Year	MRC £ million	AMRC £ million
1983–84	107 5	76.8
1984–85	117.1	86.6
1985–86	122.3	108 8
1986–87	128.3	110.2
1987–88	139 8	137.6
1988–89	149 0	148.2

Ostensibly MRC spending has risen by 40 per cent, AMRC spending by 93 per cent. But in reality MRC spending has probably been falling for some years; what looks like an average rise of about 8 per cent a year is in real terms a fall of up to 3 per cent a year. AMRC spending, by contrast, is rising in real terms, probably by about 10 per cent a year.

TABLE 3 Principal sources of support for cancer research in Britain, 1987–88

Charity	Contribution (£million)
Imperial Cancer Research Fund	38.8
Cancer Research Campaign	24.6
Medical Research Council	9 9
Leukaemia Research Fund	6.3
Ludwig Institute for Cancer Research	3 0
Institute of Cancer Research	2.0
National Health Service	2.3
Yorkshire Cancer Research Campaign	1 7
Tenovus	1.4
North of England Cancer Research Campaign	1 0
Total	91 0

Grants — often with large capital components — totalling more than £7 million were awarded by the Kay Kendall Leukaemia Fund between 1986 and 1988. Research spending for the current year is probably at a considerably higher rate for most charities, estimated at £47 million for the Imperial Cancer Research Fund and £37 million for the Cancer Research Campaign

Innovation in care

Medical research aims at innovation in health care. First-class clinical research facilities are essential to evaluate new methods both of treatment and management before they are introduced into routine use. It is difficult to imagine any better means of demonstrating the benefits (discarding those of no value) of innovation — in the short and the longer term — except through expert centres working individually or, preferably, in co-operation. These are exactly the sort of centres that CRC and ICRF have set up within the cancer field.

One other way of evaluating new treatments is simply by pooling the experiences of many different hospitals, whether or not they represent centres of research excellence. The multi-centre clinical trial or study is often the key to the evaluation of new treatment, leading to identification of unwanted effects which in turn lead to modification and improvement or to the treatment being dropped.

The government is proposing that individual hospitals will have the right to 'opt out' of central control and become self-governing. The fragmentation that will inevitably follow cannot but make the collection of information more difficult, whether as part of clinical trials of treatment, or for other purposes.

It is hard to imagine, for instance, that a study like that by Wariyar and Richmond (*Lancet* **i**, 387–388; 1989), on the relationship between low birthweight and disability, would be feasible outside an integrated health service. Such studies, which depend on centralized records, become increasingly important as medical care keeps more premature babies alive, some of whom will be disabled. Sadly, to the social and financial costs of neonatal intensive care must be added those of lifelong disablement. Even within an integrated health service it was difficult to follow up the disabled children; a 4 per cent disability rate among those "easy to find

and review" has to be compared with a 35 per cent rate in the difficult groups.

Problems of fragmentation have already hit perinatal medicine in the NHS. The number of sets of triplets born each year has virtually tripled with the emergence of private *in vitro* fertilization clinics. A single set of triplets monopolizes the intensive-care facilities of the average neonatal unit. Conceived profitably by private medicine, the problems of neonatal care for the babies falls on a health service short of money. And, of course, the chances of babies not surviving (or if they do survive, of being disabled) increase with the multiplicity of the birth.

Indeed, the ability of modern medicine to prolong life, often for very long periods, demands thorough long-term follow-up of those treated. Quality of life, rather than simply survival, becomes the overriding concern. Furthermore the long-term effects of treatment begin to make an appearance and offer evidence for one form of treatment rather than another. Perhaps nowhere so much as in cancer medicine have the two issues assumed more importance. Recently, for instance, a paper in the *British Medical Journal* (**298**, 1611; 1989) described the long-term follow-up of women with breast cancer which had been treated by mastectomy and immediate post-operative radiotherapy. The study revealed the late onset — 20 years after treatment — of a heart condition and other cancers, brought on by radiotherapy, which resulted in a measurable number of deaths.

Saving money

An aspect of clinical trials that is almost entirely overlooked is that they can save money. They may well do this in the long term by demonstrating that a particularly expensive form of treatment is not effective and so can be dropped from the repertoire. But even during a trial, half the patients may not receive an expensive treatment they would probably receive if they were not entered in the trial. A good example is the European trial of carotid endarterectomy, an operation of as yet unproven benefit, whose realistic total cost is probably about £3,000 in Britain and a great deal more in other places (1,500 operations a year are carried out in Britain, 80,000 a year in North America). The alternative to surgery is small doses of aspirin and no need for a stay in hospital.

The problems for research in a 'two tier' health service do not stop with fragmentation itself but in the quite different requirements the government may place on those hospitals staying in and those opting out. The possibility of a double standard operating with respect to medical audit is a very real one — the government has not made it clear whether it will require opted-out hospitals to provide data on their performance.

Opportunities for good epidemiological work are also threatened by the possibility of the disappearance of the NHS Central Registry. As analysis has been able to replace mere description, epidemiology has provided clues both for prevention and intervention. The government's approach to what it sees as too many general practitioners, may lead to a system in which patients go directly to consultants, as they do in many other Western European countries, with primary care being given by secondary carers. The breakdown of the system in which patients' notes follow the patients around will be a blow not only to continuity of care but also to research. Changed patterns of patient referral may have equally serious consequences for other parts of medicine. For effective clinical research, enough patients with particular diseases, or complex clinical conditions, must be concentrated in one institution. So there is little point in attempting research except in harness with the provision of a first-class clinical service. Patterns of referral to academic units in teaching hospitals which provide this level of service have often taken many years to establish. These patterns could be destroyed very easily by over-concern with costs of treatment in such centres, which will tend to be of the most modern, with knock-on costs in laboratory services. On the other hand, experience in the Netherlands, for example, suggests that patients may be sent to centres of excellence from peripheral hospitals, to spare local budgets.

The government says that it wishes to maintain a healthy environment for clinical research. That is a very welcome assertion, but nothing like enough information is being provided to show how it intends to do so. . . . At present the government's position remains untenable — the apparent failure to address the problems of research is completely at variance with its stated aim to improve the NHS.

Working Paper 2 of the White Paper states the government's intentions to introduce cross-charging of, on the one hand, the costs of clinical teaching and research to the NHS, and on the other, the provision of patient care by clinical academics and research workers. Understanding the real costs of research is likely to be beneficial. But badly carried out cross-charging will simply throw obstacles in the way of the effective running of the present three-way collaboration between medical schools, the NHS and the research financers, whether charities or the Medical Research Council.

The final threat to research lies in the possibility of changes in the pay and conditions of employment of NHS clinical staff. The problems of recruiting high-quality people into academic research will be worsened if differences in salaries between NHS and academic staff are further accentuated. Kenneth Clarke (Secretary of State for Health) does not foresee any great discrepancies here. Indeed, in his speech to the medical profession of 10 July 1989, he suggested that he would be prepared to approach the Department of Education and Science for supplements to clinical academics' pay. One can only hope that the Minister's assurances hold good.

Service costs

Again, in the same speech Kenneth Clarke announced a number of measures intended by the government to support medical education and medical research. Among them was the proposal to distribute an additional £5.5 million through Service Increment for Teaching (SIFT) to teaching hospitals, paid to provide for the service costs of research. This has been welcomed, although enthusiasm is tempered; not only is the sum very small, but the distribution of SIFT is based on undergraduate teaching numbers which do not actually correlate with research activity. Mr Clarke's intention to seek better research indicators in the future, and the intention for self-governing hospitals to be able to make additional payments to research workers undertaking NHS work (see above), are essentially positive proposals. It was also significant that he recognized that additional resources would be needed to support service costs of research in non-teaching hospitals.

Worries remain about the possibility that patterns of patient referrals might well be destroyed; about the future of specialist units within NHS hospitals; and about pay differentials. It is also disappointing that the government is not prepared to take a strong line on clinical research being an essential part of the work of hospitals that have opted out.

The government says that it wishes to maintain a healthy environment for clinical research. That is a very welcome assertion, but nothing like enough information is being provided to show how it intends to do so. There is clearly still a long way to go before those who believe in the improvement of health by research, and who put their money where their mouths are, will be convinced that the government believes the same and will act accordingly. At present the government's position remains untenable — the apparent failure to address the problems of research is completely at variance with its stated aim to improve the NHS. □

Transgenic route runs into sand

A spectacular claim that spermatozoa can carry foreign DNA into mouse eggs to make transgenic mice has not been confirmed, but there are no grounds for saying that it should never have been published.

SPECTACULAR claims make the most cruel disappointments. That is one of the lessons to be learned from the appearance in the current issue of *Cell* of a report of several parallel failures to repeat what seemed, as recently as June this year, to be a simple way of generating transgenic mice — animals carrying genes from a different species or even genus. Another may be that most genomes are remarkably resistant to accidental pollution by foreign DNA.

The tale is nevertheless interesting in itself, and also important for its bearing on the management of the scientific literature. Earlier this year, an Italian group from Rome reported their success in making transgenic mice by a variation of a standard *in vitro* fertilization process in which foreign DNA was mixed with the spermatozoa used for fertilizing mouse eggs (Lavitrano, M. *et al. Cell* **57**, 717; 1989). Put simply, the foreign DNA was supposed to be carried into the embryos by the spermatozoa, shown by the same investigation to have a propensity for picking up DNA. Nearly a third of the emergent mice were said to carry the foreign genes, which were said to be transmitted faithfully to a succeeding generation of offspring.

A report such as this was bound to engender both excitement and controversy. The excitement is easily understood. Transgenic mice are invaluable laboratory tools, chiefly as means of inferring how the expression of genes is regulated. There are now several techniques for making them, ranging from the microinjection of DNA into fertilized egg cells to the use of retroviruses carrying segments of foreign DNA together with appropriate controlling elements. But whatever the technique, a transgenic mouse is necessarily a hit-or-miss construction. Among the reasons for the excitement over the Italian report last June is the simplicity of the technique and the success rate reported — nearly a third of the viable artificial embryos emerging seemed to carry foreign DNA.

The reasons why the original report must have aroused controversy are also not far to seek. For one thing, it is surprising that individual spermatozoa can pick up foreign DNA, either as circular plasmids or straight pieces of helical DNA, yet Lavitrano *et al.* reported that up to 4,000 copies of a plasmid (loaded with an antibiotic resistance gene for easy detection) may be taken up by a single sperm. Given that, it may have been less surprising that the foreign DNA seems to be integrated in the mouse genome, but last June's speculation that the mechanism might have been responsible, in the course of evolution, for the transfer of genetic material between species was bound to send shivers down many a spine. In a comment accompanying last June's publication in *Cell*, Max L. Birnstiel and Meinrad Busslinger understandably compared the report with the earlier reports of what is now known as 'cold fusion'.

That is the excitement and the controversy. The disappointment is the letter from four well-known mouse-genome manipulators (Ralph L. Brinster, Eric P. Sandgren and Richard R. Behringer, all from the University of Pennsylvania, together with Richard D. Palmiter from the University of Washington at Seattle) in the latest issue of *Cell*. They say that they have failed to confirm the integration of foreign DNA into artificially fertilized mice in eight series of experiments, two of which followed essentially the same experimental protocol as the Italian. For good measure, they also report that seven other laboratories, spread from Budapest to Pasadena, have similarly negative results.

So what can have gone wrong? One possible answer is simply, "Nothing". *Cell* also publishes in its most recent issue a letter from Lavitrano *et al.* that is a model of how people whose results are not confirmed should respond to challenge: "the inability to reproduce our results . . . suggests . . . a serious problem of which we were not aware", "when we received news of negative results . ., we re-examined the procedure . . . no obvious point has so far emerged", and so on By the account of Brinster *et al.*, the authors have also readily responded to requests for reagents and other materials that would allow exact replication of their protocols. Lavitrano *et al.* volunteer that, while continuing to study their transgenic mice, they are also planning that their work should be repeated at another laboratory. It may yet emerge that the original report was correct, but valid only in the particular circumstances of the Rome experiment. It seems unlikely that the phenomenon described will be more generally valid.

Meanwhile, attention will concentrate on one still-puzzling feature of the original report. The plasmid DNA apparently easily incorporated into mouse spermatozoa and thus into mouse genomes was distinguished by two sites at which it could be cut by a particular restriction (cutting) enzyme, but the foreign DNA incorporated into intact mice seemed to have lost one of these sites. Everybody concerned has followed the original suggestion that there must be some process at work that rearranges the DNA before it is incorporated, but that is almost as puzzling a circumstance as the possibility that spermatozoa can pick up thousands of copies of plasmid DNA from the medium that surrounds them.

So there remains the question provoked by Brinster *et al.*, who round off their report of their failure to replicate the original results with some homilies on the proprieties of the publication process. They make four points, three of which are platitudinous: exciting research reports do not always emerge from distinguished laboratories; the more "important" are claims, the more quickly will they be tested; and verifications (or the opposite) should first be reported in science journals, even if they are afterwards put out in press releases. Almost everybody will agree.

The fourth point is the puzzle. Brinster *et al.* say that "the central aspect of the process of verification is the objective and methodological resolution of a question . . . best accomplished in a cooperative manner . . . as is occuring . . . in this case." They add that, whatever the outcome of the investigations now planned, "those in research, and others . . ." will have learned a lot about "how scientific knowledge evolves" (*sic*).

Will they? Brinster *et al.* would have done better to acknowledge that there is a further question to be asked: is the peer-review system the universal safeguard against error it is supposed to be? In an ideal world, referees can keep on asking questions of authors who report extraordinary results until all possible doubts are exorcised, but that is not the real world in which we live. Implicit in what Brinster *et al.* say is their assumption that people with remarkable results to report have a right to see them published quickly. But may it not be that it is the extraordinary results that need most checking time?

John Maddox

EARTHQUAKES

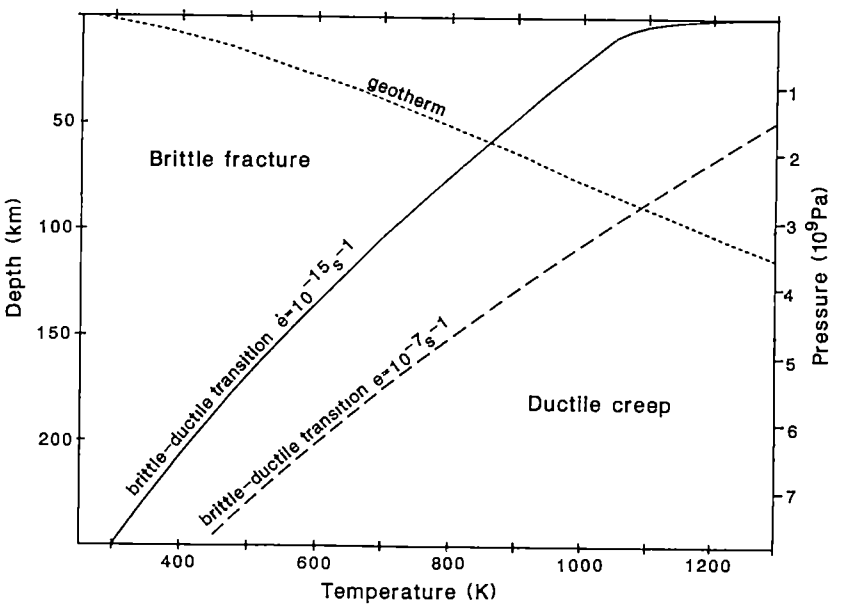
New rumbles on deep sources

Cliff Frohlich

As ordinary materials become ductile at the pressures and temperatures that must exist 70–700 km beneath the Earth's surface, how is it possible for earthquakes to occur there? A persistent dialogue for the past 60 years between seismologists and experimental geophysicists has revealed much about the structure and mechanics of the Earth's mantle, but the origin of deep-focus earthquakes remains unidentified. On page 733 of this issue[1], Green and Burnley present new laboratory data that suggest a plausible solution to the problem.

The dialogue began in the 1920s, when Harold Jeffreys dismissed suggestions that some earthquakes occur at great depths by pointing out that the Earth's mantle had no strength. Laboratory experiments show that at high temperatures and pressures, rocks ordinarily do not fracture catastrophically (see figure), as they do in earthquakes. Instead, under applied stresses they deform in a ductile fashion, like pitch. Jeffreys knew that the Earth's mantle must flow in this way because we observe glacial rebound in response to the disappearance of great masses of ice, and because the Earth fails to support mountains with elevations greater than 10,000 metres or so. In 1928, however, Kiyoo Wadati[2] published a remarkably thorough study of the seismograms of some Japanese earthquakes, proving conclusively that some of them really do occur at depths of many hundreds of kilometres.

Thus was born the paradox of deep earthquakes. How can they possibly occur, in the light of Jeffreys's objections? This is an important question, especially as in a typical year about one quarter of all earthquakes recorded occur at depths exceeding 70 km. (The recent Californian earthquake, of course, does not belong to this category, having arisen at about 18 km depth.)



The first suggestion was that deep earthquakes might be implosions, occurring when olivine in the mantle suddenly transforms to a more dense spinel structure. Although the pressures necessary to transform natural olivine to spinel were not obtained in the laboratory until 1966, as early as 1936 J.D. Bernal had suggested that a phase transformation must occur. Bernal inferred this from laboratory experiments with olivine's germanate analogues, in which the silicon in $(Mg,Fe)_2SiO_4$ olivine is replaced by germanium. This produces a synthetic rock that undergoes phase changes at a fraction of the pressures of natural olivine. But does a phase transformation produce deep earthquakes? The seismologists' clear and immediate response[3] was that the radiation patterns from deep earthquakes possess quadrants of compressional, as well as dilational, motion, unlike that to be expected from an implosion.

In short, deep earthquakes look much like shallow earthquakes. But, as suggested by the figure, they cannot be produced by the same mechanism. Moreover, theories of fracture have been successful at explaining shallow earthquakes as the result of the opening and coalescing of myriads of tiny cracks. Straightforward physical arguments suggest that it is physically impossible to open cracks at mantle pressures.

Occasionally, ideas are so attractive that they are maintained despite contrary evidence. So it has been with the idea that phase transitions are related to deep earthquakes. In the past half century, more than a thousand papers concerning deep earthquakes[4], earthquake mechanics and mantle rheology have appeared. It is now certain that phase transformations occur in mantle materials at depths near 400 km (olivine–spinel) and 670 km (spinel–oxide), close to the depths of the deepest earthquakes. Plate tectonics provides a means of conveying cold rock, and possibly wet sediments, down past these depths in the deep earthquake zones. Surely phase changes in these materials are linked with the earthquake process?

Green and Burnley's suggestion is an interesting development. From low-pressure experiments[1,5] on the olivine-analogue germanate Mg_2GeO_4, they find that the phase transition depends critically on the shear stress as well as on the hydrostatic stress. Although stress is relieved by ductile flow at both low and high temperatures, they find a narrow temperature range where there is unstable, catastrophic failure as tiny lenses of spinel form and link up as 'anticracks' along the plane of maximum shear stress. A shear-stress dependent mechanism depending on the occurrence of transitions along a planar region is attractive for several reasons[6]. It does not require that a large volume of material changes phase during a large earthquake. And it could explain why seismologists find no deep earthquakes beneath about 670 km, because at about this depth the spinel–oxide transitions are complete and no more phase transformations are available.

In short, deep earthquakes are fundamentally different from shallow earthquakes. Or are they? In 1966 Raleigh and Paterson[7] suggested that the presence of water disassociating from serpentine rocks might change the effective stresses at the source of deep earthquakes, and even keep cracks open. Fluids injected in wells near Denver had apparently lowered the effective stress and caused a series of shallow earthquakes beginning in 1962. If such a mechanism explains the Denver earthquakes, why could it not work at greater depths as well? Expressed in terms of the figure, the effect of the fluid is to alter the mechanics so that everything behaves as if it were at shallower depths. Serpentine is basically just olivine and water, manufactured in oceanic lithosphere when ocean water interacts with crustal

Relationship between pressure (depth), temperature, strain rate $\dot{e}$ and 'ordinary' rock failure. As either temperature or pressure increases, the rock failure process changes from a catastrophic fracture (earthquakes) to ductile flow. Because the geotherm meets the failure curve at pressures corresponding to depths of 70–100 km, we expect earthquakes to be confined to the Earth's lithosphere. Even if the temperature is hundreds of degrees cooler in subduction zones, ordinary brittle fracture cannot occur at the depths of the deepest earthquakes. What, then, is the mechanism that allows them to occur? (Figure from ref. 4.)

and mantle material. At sufficiently high temperatures and pressures, serpentine disassociates into olivine and water, and thus at greater depths this might allow cracks to open and earthquakes to occur.

This hypothesis seems to be substantiated by laboratory studies presented at a recent meeting of the American Geophysical Union by Charles Meade and Raymond Jeanloz[8]. They find that only when serpentine is present can they measure acoustic emissions (presumably caused by microscopic earthquakes) in tiny samples of olivine squeezed in their diamond-anvil apparatus and heated to mantle conditions. These results are preliminary, and one may object that even if water or another liquid is present, it seems unlikely it would achieve pore pressures sufficiently high to open cracks. But they will be important if they hold up, because they seem to demonstrate earthquake-like failures in samples of real mantle materials at pressures and temperatures found in the mantle.

In addition, Meade and Jeanloz[9] find acoustic emissions in stressed samples of pure silicon and pure germanium at pressures corresponding to depths of 1,500 km in the mantle. Although no-one believes that pure silicon or germanium occur in the mantle, these experimental results are significant because they prove that phase transitions can produce earthquake-like behaviour at pressures well above the brittle–ductile transition. The troublesome wrinkle is that such behaviour apparently may be produced by more than one possible mechanism.

So what should we believe? Do deep earthquakes occur because of phase transitions, because of fluids, or for some entirely different reason? Are deep earthquakes mechanically like shallow earthquakes, or fundamentally different? Fifty years of science has turned up several possible ways to resolve Jeffreys and Wadati's dilemma, of which Green and Burnley's is the latest. Currently, the biggest uncertainty with their results is that they perform their experiments on germanate analogues at only about one-tenth of the pressures at the focus of the deepest earthquakes. For their proposed mechanism, which acts only over a narrow range of temperature, it needs to be demonstrated that the analogy between germanate and silicate behaviour holds true under more severe conditions. The good news from the new work is that laboratory rock-mechanics experiments are finally approaching conditions in the mantle, and so the dialogue about the deep earthquake mechanics can be fuelled by laboratory observations instead of mere speculation. □

PALAEONTOLOGY

Neck and neck

Michael A. Taylor

THE superb fossil reptiles from the Middle Triassic sediments of Monte San Giorgio in Switzerland[1] have attracted intense research interest for more than half a century, but there are still some intriguing problems to be solved. One of the more puzzling is the lifestyle of *Tanystropheus*, a reptile with a neck half the length of its entire body, yet made of only twelve vertebrae, each one grotesquely elongated. Despite the fine fossil evidence available, the function of this neck is not fully understood even after an extensive study by Wild[2,3] and a new interpretation by Tschanz[4].

The 230-million-year-old Monte San Giorgio sediments, now on top of a mountain in the Alps, were deposited in a small, nearly land-locked basin 10 km in diameter with access to the Tethys Sea. They have yielded a range of sizes of the largest *Tanystropheus* species, *T. longobardicus*, from small juveniles 50 cm long to adults up to 6 m long. The adults were predators, catching fish and cephalopods with conical, recurved teeth, as confirmed by stomachs containing hooklets from cephalopods' arms. Nevertheless, they were poorly streamlined and do not seem to have been efficient swimmers. They used their webbed hind limbs for propulsion in the water, but were fully able to walk on land. The tail may also have been used for swimming but can hardly have been essential, as specimens have been found in which the tail has been shed by autotomy, like modern lizards, presumably to distract predators.

The most problematical aspect of *Tanystropheus* is its grossly elongated neck. Wild suggests[2,3] that it was flexible and used for catching food: the animal would have used the head and neck for fishing for prey, while the rest of the body remained on the shore. Alternatively, the animal could have dabbled when floating at the surface (like modern ducks) or darted at prey while swimming. When walking on land, the animal would have held up its neck in a sigmoid curve, rather like a swan.

But Tschanz[4] argues that the neck was both too stiff and too weak for such a lifestyle. The thin, elongated ribs of the neck vertebrae ran below and to either side of the vertebral column, each overlapping several other vertebrae. These ribs stiffened the neck against vertical bending. The relatively shallow vertebrae provided very little area of attachment and very short lever arms for the neck muscles which were probably too weak to pull the neck up into an S-curve against gravity, especially a neck stiffened by ribs.

In Tschanz's view the animal had to hold its neck more or less straight out in front and would surely have found active life on land difficult: it may not even have been strong enough to have held its neck above the ground, let alone in a sigmoid curve. But in the water, the weight of the neck would have been relieved by buoyancy, and its stiffness would have helped the animal to swim without interference from bending of the neck and the resulting yawing.

The relatively long, unstreamlined body of *Tanystropheus* suggests that it either hunted slow prey or ambushed fast prey before it could escape[5]. This strategy would suit an animal living close inshore in relatively shallow water, where the bottom and plants provide cover. But the stiffened neck seems inappropriate for this strategy. Perhaps it could still dart its neck at prey, using the residual sideways flexibility to move its open mouth over the prey.

Juveniles of *T. longobardicus* had relatively short necks and teeth that were triply cusped like those of some insectivorous lizards. Wild suggests that they hunted insects and became fully marine only when adult. But Tschanz's view of the neck as a stiff structure applies to juveniles as well as adults, making it hard to see how juveniles could have caught insects at all. The teeth are similar to those of *Amblyrhynchus*, the modern marine iguana of the Galapagos, which feeds on algae, and one author has proposed that juvenile *T. longobardicus* did the same[6]. But the iguana has a short, flexible, powerful neck which helps it tear plant material from the rocks. It is hard to imagine a stiff-necked *Tanystropheus* doing this.

It may be that guessing the function of the long neck is the wrong approach to the problem. A comparison of growth in several species of *Tanystropheus* and related forms suggests that increases in the relative length of the neck preceded overall increases in body size in evolution[2,3]. Wild concluded that the long neck was an adaptation for efficient foraging,

enabling the body size to increase.

But Tschanz's analysis, using different baselines, indicates that most of the growth of the neck of *T. longobardicus* during life can be explained as a strong and almost constant positive allometry: the neck length is linearly related to a power greater than unity of the animal's dimensions. Furthermore, a similar pattern of growth is found in the related but much smaller *Macrocnemus bassanii*. This needs confirmation from other species, but implies that the neck of *T. longobardicus* is as long as one would expect in any *Tanystropheus* of this size. Its great length in this species may therefore be an indirect consequence of the evolution of large size for some other reason, such as sexual competition or defence. Also, the positive allometry of neck growth in *T. longobardicus* seems to be weaker than in *M. bassanii*, hinting that this, the largest species of *Tanystropheus*, was approaching the longest viable length of neck — hardly surprising as the animal risked tipping over onto its nose every time it came out onto land. So, perhaps, *T. longobardicus* had a long neck simply because it was a big animal, and it survived in spite of it rather than because of it. □

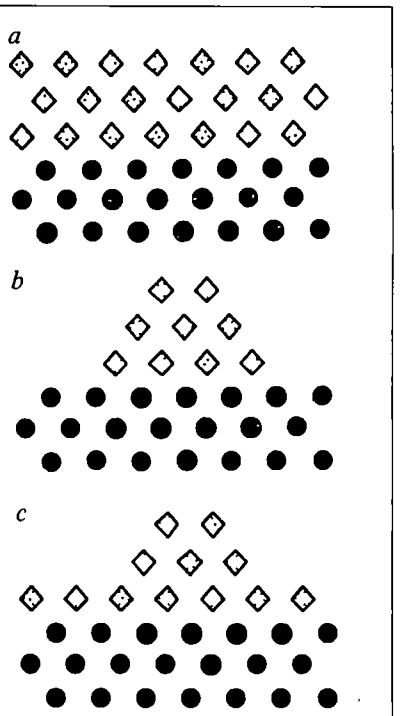
SURFACE PHYSICS

Controlling crystal growth

Colin Humphreys



EPITAXY, from the Greek 'arranged upon', describes a mode of crystal growth in which the atoms of one crystal are registered perfectly on the atoms of another. (DNA can also be regarded as a kind of epitaxial structure, Watson and Crick originally suggesting that one DNA helix 'crystallizes' on another which acted as a template.) Epitaxial structures are becoming increasingly important in materials science, physics, chemistry and electronics. For example, solid-state lasers can be built from epitaxially grown layers of two different semiconductors, say GaAs and AlGaAs. For most man-made structures the aim of epitaxy is to grow crystal A upon crystal B with an atomically flat and defect-free interface between A and B. But if the deposited material A has a larger surface energy than the substrate B, A will roll up and form islands on B. Now, M. Copel *et al.* suggest (*Phys. Rev. Lett.* **63**, 632–635, 1989) a novel way to over come this problem: the use of a surfactant, which is a 'wetting agent' that changes the surface energy so that A spreads out as a thin film on B. The idea may eventually give increased control over epitaxial growth and enable epitaxial structures that have previously been thought impossible to be grown.

With real control of epitaxy, new materials could be fabricated atomic layer by atomic layer, each layer acting as a template for the next. This has yet to be achieved for alternating monatomic layers of different compounds, but the possibility that single crystals of such materials could have radically new properties makes the quest for perfect epitaxy a leading focus in materials science. The main impediment to this is that if A wets B, then B does not wet A, so that growing high quality ABAB multilayers is difficult and the use of surfactants is potentially very important.

In practice, epitaxy occurs according to one of three distinct growth modes as shown in the figure: layer-by-layer (Frank–van der Merwe (FM) growth); three-dimensional island growth directly on the substrate (Volmer–Weber (VW)); and a mixture of the above — initially layer-by-layer growth for a few layers followed by island growth (Stranski–Krastanov (SK)). If A and B are identical materials then a single crystal can of course be grown, layer-by-layer, by various experimental techniques. But if A and B differ, their atomic spacings will differ and the result will be a strained epitaxial system. It can be shown theoretically that layer-by-layer growth of a strained system is not possible in equilibrium, which would seem to rule out the potential of epitaxial growth. Fortunately, kinetic constraints on mass transport can result in layer-by-layer growth and the resulting structures, although not in equilibrium, are metastable and can last for a long time.

As mentioned above, whether growth occurs layer-by-layer or via islands in such structures depends upon relative surface energies: if the deposited material A has larger surface energy than the substrate B, then island growth will tend to occur. (The situation is slightly more complicated than this because interface and strain energies must also be considered.) The problem is analogous to that of a liquid drop on a surface. Will it spread out to make a monolayer thin film (like oil on water) or will it form an island (like mercury on glass)?

Copel *et al.* have performed both calculations and experiments on the epitaxy of germanium and silicon, of which Ge has the lower surface energy. Hence, Si grows on Ge by island growth (VW mode), but Ge grows on Si initially layer-by-layer, then by island growth (SK mode). Copel *et al.* show that a monolayer of arsenic can be used to reduce the surface energies of both Ge and Si. In addition, the As segregates to the surface during growth (there is little point in using a surfactant if it stays at the interface).

Three types of epitaxial growth: *a*, Frank–van der Merwe (FM); *b*, Volmer–Weber (VW); *c*, Stranski–Krastanov (SK).

The authors claim that by covering the substrate surface with As, they promote the layer-by-layer growth of both Ge on Si and of Si on Ge. If substantiated, this result will be very important. But further work is needed to characterize the quality of the epitaxial growth, and the extent to which As is incorporated in the growing layers must be more thoroughly investigated. Nevertheless, the control of epitaxial growth using surfactants as suggested by Copel *et al.* provides a potentially important new avenue to 'evade equilibrium thermodynamics' and produce high-quality epitaxial layers of structures that have previously proved impossible. We know now that enzymes mediate the growth of one strand of DNA upon another. Could biology be pointing the way to growth of perfect man-made epitaxial structures using mediators such as surfactants? □

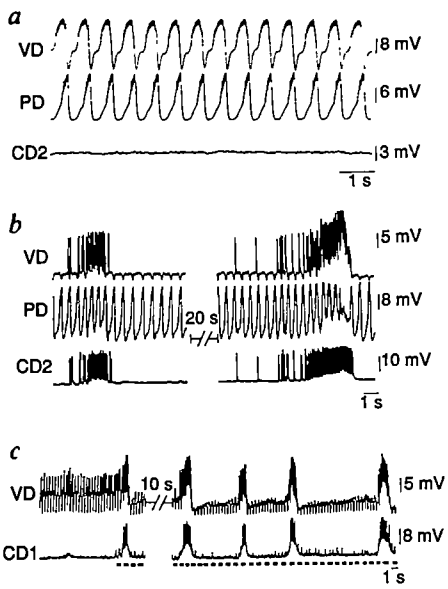
NEUROPHYSIOLOGY

Twitching and switching

Allen Selverston



SINGLE-CELL recordings from both vertebrate and invertebrate neuronal networks suggest that certain types of neurons can be identified by their unique physiological characteristics. Usually, the local connections made by the cell are unknown, but it is generally assumed that each cell's functional connections are constant, as they are what give the cell its particular signature. That this may not be the case has recently been demonstrated in both the lobster[1] and the crab[2].

In the case of the lobster, Hooper and Moulins show that a neuron — the VD cell — that has long been considered part of the central pattern generator controlling the rhythmic movements of the posterior foregut, or pylorus, can instead switch to the network that controls the rhythms of the anterior foregut, or cardiac sac, whenever this network is active. The underlying mechanism for the switch can be ascertained because much of the synaptic connectivity is known[3] and new information about sensory feedback and neuromodulation for the stomatogastric system has recently become available[4–6].

The VD cell receives synaptic input both from other cells of the pyloric central pattern generator and from neurons of the cardiac sac network. When the cardiac sac rhythm is silent, the VD neuron bursts in time with the pyloric pattern. Like the other pyloric neurons, it has intrinsic bursting pacemaker potentials whose expression depends on descending inputs from higher centres to the stomatogastric ganglion. In addition, when active, the VD and the other pyloric cells express 'plateau' properties so that a short depolarizing pulse triggers a long-lasting depolarizing plateau. These active membrane properties plus the extensive synaptic connections act in concert to produce the normal pyloric pattern (part *a* of figure).

Either by stimulating a particular sensory receptor in the stomach wall or by activating the receptor's nerve directly, Hooper and Moulins were able reliably to activate the cardiac sac rhythm *in vitro*. Remarkably, this activation was accompanied by an instantaneous switching of the VD neuron from the pyloric pattern to the cardiac sac pattern (parts *b and c* of figure). How does this come about? The pyloric synaptic inputs to VD remain intact, as indicated by rhythmic synaptic potentials. But, surprisingly, all the regenerative properties of the VD neuron, bursting and plateau potentials, totally disappear.

With the active membrane responses in VD absent, the cell now responds to the strong input from the inferior ventricular (IV) cell of the cardiac sac network. The other cells of the pyloric rhythm respond transiently to mechanoreceptor stimulation, but immediately return to their normal activity upon cessation of stimulation. This is strong evidence for the release of a neuromodulator during the stimulation of the mechanoreceptors and its exclusive action on the VD neurons, causing them to become passive but allowing them to be activated by bursts of synaptic excitation from the IV cell (part *b* of figure). It is this mechanism that appears to be the basis for the switch from one network to the other.

The VD neuron can fire either with *a*, the pyloric network (PD neuron trace) or *b*, the cardiac sac network (CD2 neuron trace). *c*, Tonic stimulation (dotted line) of a sensory nerve, the lpln, activates the cardiac sac network (CD1 neuron trace), and the VD neuron switches from the pyloric network pattern (left) to the cardiac sac network pattern (right). Taken from ref. 1.

Direct stimulation of the IV inputs does not suppress the regenerative properties of the VD cell, so the source of the putative neuromodulatory substance must originate elsewhere.

Previous work from Moulins's laboratory has shown that a single cell of an upstream ganglion releases acetylcholine into the stomatogastric ganglion, activating muscarinic receptors[7]. Such neuromodulators appear to act by activating receptors which trigger second messenger systems thereby altering both cellular properties[8] and synaptic strengths while the modulator is present and for some time afterward. As a result, there can be a major functional 'rewiring' and significant alteration of the pyloric pattern. Subsequently, many laboratories have demonstrated both the presence and the physiological effects of different modulators on both the pyloric and gastric mill of the stomatogastric system[9]. Amines and peptides are particularly effective; both can be delivered to the stomatogastric central pattern generators either via the blood or by direct local release into the neuropil of the stomatogastric ganglion[10] (although there has been no evidence to suggest that that they cause neurons to switch networks).

Sensory feedback loops, which can alter the pattern via conventional synaptic action[11], are a recently described source of neuromodulators. One feedback loop uses stretch receptors in both gastric and pyloric muscles (the gastro-pyloric receptors) to affect the gastric pattern on a cycle-by-cycle basis while modulating the pyloric pattern over longer periods[12]. Remarkably, these receptors contain both acetylcholine, which acts on nicotinic receptors of gastric cells, and serotonin, which acts on particular cells of the pyloric system. An interesting possibility, therefore, is that the modulator affecting the VD cell is released by the sensory neurons which are stimulated to activate the cardiac sac rhythm.

The fact that VD switching occurs following mechanical stimulation in semi-intact preparations argues that this phenomenon may be of biological significance in lobsters, but it is not yet clear how the loss of the VD neuron affects the functioning of the pyloric system. As VD is a motor neuron, the muscle it controls must perform a different role when it is part of the cardiac sac rhythm. But the precise nature of the behavioural effects for each separate rhythm remain to be elucidated.

That the phenomenon described by Hooper and Moulins may be widespread is suggested by the report at a recent conference[2] of comparable findings in the crab foregut. Dickinson, Mecsas and Marder reported that the red-pigment-

concentrating hormone increases the synaptic interactions between the cardiac sac and gastric mill neurons to such an extent that the entire gastric mill fires with a cardiac sac rhythm. Virtually all of the gastric neurons must be switching to allow the operationally independent gastric mill and cardiac sac central pattern generators to act as one functional unit.

The idea of sharing neurons between networks may confer some as yet unexplainable computational advantage on small systems. It adds further complexity to a specific well-defined system already shown to be extremely versatile in its response to modulators. Moreover, it suggests caution in interpreting the data from single cells of more complex systems; if the chemical environment can switch a neuron from one circuit to another, the hypercomplex cell of one preparation may be the simple cell of another. □

METEORITICS

Antarctic differences of opinion

I. P. Wright and Monica M. Grady

THE flux of interplanetary debris delivers meteorites more or less uniformly to all parts of the Earth's surface, yet there is evidence to suggest that the meteorites collected in Antarctica represent a different population from that found elsewhere. Such evidence was presented at a recent meeting* to discuss this distinction, and there was much debate as to whether any differences were real or artefacts. Those with partisan views were unlikely to have changed their opinions about the meaning of the apparent differences between Antarctic and non-Antarctic meteorites in the light of presentations at the meeting. But the idea that the two sample sets may represent some sort of difference in meteorite sources remains a fascinating possibility. The effects of terrestrial weathering must first be constrained, however, if the differences are to be attributed to preterrestrial phenomena

The first evidence of a distinction was presented by M. E. Lipschutz and colleagues (J. E. Dennison *et al. Nature* **319**, 390–393; 1986) on the basis of volatile/mobile trace-element compositions of *H5* ordinary chondrites collected from Antarctica and elsewhere. Another apparent difference reported since is that certain meteorite types have thus far only been found in Antarctica. These include polymict brecciated eucrites, lunar meteorites and low FeO ureilites (the last of which also have distinctive oxygen isotope compositions). Antarctic and non-Antarctic carbonaceous chondrites show differences in chemistry, oxygen isotope composition, extent of aqueous alteration and heating; these effects are undoubtedly due to preterrestrial processes. But do the observed differences document separate meteorite populations or do the data simply extend the currently known ranges in the properties of individual meteorite groups?

Another difference between Antarctic and non-Antarctic meteorites is the higher ratio of H- to L-group chondrites in the Antarctic collection. On closer examination, however, the enhanced ratio is the result of an excess of H-group chondrites from just one Antarctic collection area. Thus, the recent addition of a single shower fall of H-group chondrites to this region would distort the H/L ratio of Antarctic meteorites, which would otherwise be similar to that from the rest of the world (G. Huss, University of Chicago). Critics of this hypothesis include R. Harvey (University of Pittsburgh), who warned that the shower would have had to be anomalous to explain the relatively large numbers of small fragments present in the Antarctic collection. The continued recovery of meteorites from Antarctica should help to settle this debate.

If the distinctions are real, what are the reasons? Are the differences the result of preterrestrial processes, so that they can yield interesting clues about the Solar System, as Lipschutz (Purdue University) maintains? Or is a mixture of selection and weathering effects at work? An important distinction between Antarctic and non-Antarctic meteorites is the range of their terrestrial ages: samples collected from observed falls are no more than about 200 years old; by contrast, Antarctic finds may have fallen over the past million years. It is not expected, however, that the parent population has changed over this period. The temporal decay of a meteorite flux, attributable to collisions in the asteroid belt, takes 10^7 years (G. W. Wetherill *Nature* **319**, 357–358; 1986).

Also, the mean size of Antarctic meteorites is much less than that of non-Antarctic samples. Clearly, this is because small fragments are more readily seen when exposed on ice rather than elsewhere. But frequently, numerous small fragments originate from a single fall that broke up in the atmosphere, on impact or subsequently. Thus, although collections include more Antarctic meteorites than non-Antarctic, statistical analyses should rely on their total mass, and not their number, to be reliable.

Complications arise from loss mechanisms that must operate in the Antarctic, the effects of which are not fully understood: small fragments are blown away by the wind, and large fragments may sink into the ice. Furthermore, the collected mass for non-Antarctic meteorites can be much less than that which originally struck the atmosphere. For example, the Revelstoke fireball caused huge atmospheric detonations and the impact was recorded by seismographs, yet the collected meteorite amounted to only 1 gram Similarly, immediately following a meteor shower over India, only a few large pieces were collected. Over the following three years, however, a coordinated search with the assistance of school children expanded the collection by several hundred pieces.

The idea that the differences are preterrestrial is not supported by the cosmic-ray exposure ages of H-group chondrites (L. Schultz, Max-Planck-Institut für Chemie), by their major- and minor-element chemistries (E. Jarosewich, Smithsonian Institution), or by their indigenous carbon content and isotope composition (M. M. G.), none of which vary between Antarctic and non-Antarctic samples. If the meteorites are from different sources, then the first finding would imply that two independent source bodies broke up by chance at the same time to supply the putative separate populations.

A possible explanation of the chemical and isotope differences that do exist is terrestrial weathering. Unfortunately, the nature of terrestrial weathering is not well understood: M. A. Velbel (Michigan State University) demonstrated the ineffectiveness of the weathering categories used by NASA's Antarctic meteorite curatorial facility. The modest improvement in weathering classification (to indicate the presence of surficial evaporite deposits) seems a long way short of an adequate description of the weathering histories of Antarctic meteorites. It is difficult to conceive a convenient and rapid screening procedure (over 1,000 meteorite fragments were collected in the US collection programmes in the 1988–89 season alone). Furthermore, the effects of weathering might extend to considerable depth within a meteorite sample (D. W. Mittlefehldt, NASA Johnson Space Center, Houston). Researchers who analyse 'interior' samples should be aware that such materials are often obtained by simply breaking open a meteorite — it is probable that fracturing takes place along pre-existing cracks, which may have been inundated with terrestrial fluids. □

I. P Wright and Monica M Grady are in the Department of Earth Sciences, The Open University, Walton Hall, Milton Keynes MK7 6AA, UK.

IMMUNOSUPPRESSION

Convergence of drug action

Robert B. Freedman

Two papers on pages 755 and 758 of this issue[1,2] add a further intriguing twist to the emerging connection between immunosuppressant drugs, the cytosolic proteins that bind them and the enzymatic activity of those proteins. Earlier this year, Fischer *et al.*[3] and Takahashi *et al.*[4] showed that the protein, cyclophilin, which binds the immunosuppressant drug cyclosporin A with high affinity and is assumed to mediate its action, has prolyl-peptidyl *cis-trans* isomerase (PPIase) activity. Their work also showed that cyclophilin is identical to a previously identified PPIase[5], and that the PPIase activity is specifically inhibited by cyclosporin. Now, two groups that have been exploring the action of the structurally distinct immunosuppressant, FK506, report[1,2] that it, too, is bound by a specific cytosolic binding protein with PPIase activity, but that this binding protein is quite distinct from cyclophilin.

The two groups, Siekierka *et al.*[1], at Merck, Sharp and Dohme, and Harding *et al.*[2], at Harvard and Yale Universities, were following up the finding (see ref. 6) that the macrolide FK506 is a distinctly more potent immunosuppressant than the cyclic peptide, cyclosporin, which is widely used for prevention of graft rejection in organ transplantation. Siekierka *et al.*, having previously shown that FK506 bound to a cytosolic protein[7], purified this protein from the JURKAT T-cell line. Harding *et al.* have synthesized affinity matrices containing cyclosporin-and FK506-derived ligands for affinity chromatographic purification of the corresponding binding proteins from human and bovine tissues. Both groups found that the purified FK506-binding protein is distinct from cyclophilin in terms of size and N-terminal sequence (and, indeed, is unrelated to any sequence in the current database). Both groups used radioligand binding assays and competitive binding studies to characterize the ligand binding activity; Siekierka and colleagues found that FK506 binds to its protein with a 1:1 stoichiometry, and an affinity close to 1 nanomolar.

Most importantly, both groups demonstrate that the purified FK506-binding protein has PPIase activity, although the activity towards the conventional PPIase substrate (a substituted proline-containing tetrapeptide) is 20–25-fold lower than that of cyclophilin. And finally the groups show that cyclophilin and the FK506-binding protein are quite distinct in terms of specificity; cyclophilin binds, and is inhibited by cyclosporin and shows no recognition of FK506, whereas the converse holds for the FK506-binding protein. This difference in specificity is seen most clearly in the kinetic results of Siekierka *et al.*, which show complete inhibition of each receptor by its corresponding ligand at concentrations where the other drug has no effect whatsoever.

Minor differences between the results reported in the two papers indicate that the story is far from complete. The binding protein purified by Siekierka *et al.* has a relative molecular mass (M_r) of 11,000 and shows saturable ligand binding at concentrations in the nanomolar range, whereas the protein purified by Harding *et al.* has a M_r of 14,000 and is not saturated at ligand concentrations up to 1 micromolar. Although these discrepancies may derive from the fact that the proteins come from different species, and from the use of distinct FK506 derivatives as radiolabelled ligands, possibly a diverse family of proteins is involved. Siekierka and colleagues do not report any sequence for their protein, so it is not certain that the proteins purified by the two groups are identical.

In the light of earlier data, which indicate that FK506 and cyclosporin act on T-lymphocytes in essentially equivalent fashion[8], the new data suggest that the two drugs act through distinct pathways but that their modes of action converge on PPIases. Current data show that these proteins are abundant and are important in mediating the activation of T cells, but how and why this activation exploits their ability, as PPIases, to catalyse rotamerization of peptide bonds to prolyl residues, remains completely mysterious. Far less mysterious is the fact that this new clue to the action of a class of drugs with multi-million-dollar sales, is now generating vigorous research activity. □

ASTRONOMY

Galactic chemical evolution

R. F. Carswell

Distant galaxies, that is those at high redshift, are seen as they were at a much earlier epoch in the history of the Universe. From their forms and distributions, it is hoped to learn what unseen effects in earlier epochs led to their formation. From their spectra, it is hoped to learn their chemical compositions which, in turn, should tell us about the progress of stellar nucleosynthesis in the early Universe. Two groups now report[1,2] the measurements of the spectral lines of zinc in galaxies illuminated by bright background quasars. Because zinc is one of the few elements that do not become bound into interstellar grains (where they would be invisible), these spectra give us the best measure yet of early nucleosynthesis.

Element synthesis in the primordial fireball during the first few thousand seconds of the Universe yielded almost exclusively isotopes of hydrogen and helium. All the other elements, referred to as the heavy elements, were made later in stars after they and galaxies coalesced out of the initial material distribution. The heavy-element enrichment of the interstellar medium in our Galaxy and in others occurs when the processed materials from stars is ejected, either relatively slowly through stellar winds or explosively if the star becomes a supernova. This medium partakes in subsequent star formation, nuclear burning and further enrichment of the interstellar medium.

Information on the details of the chemical history of our Galaxy has been obtained from studies of the heavy-element abundancies in the atmospheres of stars for which age estimates are available. The overall picture is that some initial enrichment of elements such as carbon, nitrogen and oxygen occurs relatively quickly from processing in short-lived, high-mass stars. After 10^9 years or so the iron-group elements appear in the interstellar medium when longer-lived, lower-mass stars yield significant quantities of material. The rate of enrichment depends on the relative numbers of stars at various masses and their formation rate, the fraction of the stellar ejecta which escapes from the Galaxy completely, and any accretion of primordial material into the Galaxy.

An independent study of the chemical history of galaxies can be made by analysing the element abundances at high redshifts when they (and the Universe) were much younger. At present, the only way of doing this with any reliability is to examine the spectra of bright high-redshift quasars for absorption lines from hydrogen and heavy elements which arise

in gas in the galaxies that lie between us and the quasar. The strengths of these lines may be used to infer both the relative gas-phase abundances of the ions responsible, and, through some corrections for relative populations of different levels of ionization, the relative element abundances in the interstellar gas.

There is a major complication that has to be considered if one wishes to infer the true abundances from the gas-phase abundances. In the interstellar medium in the Galaxy, much of the material for the common elements (such as carbon, oxygen, silicon and iron) goes into the formation of interstellar dust grains, so that the true abundances of these elements are somewhat higher than the gas abundance would indicate. Only for a few relatively rare elements, notably zinc, is there negligible depletion onto dust, and only through measurement of the abundances of these are we likely to obtain an accurate picture of the heavy-element abundances in high-redshift systems.

Detecting the zinc lines is difficult because of the weakness of the lines even for abundances typical of those in our Galaxy, and the possibility of lower abundances at high redshift increases this difficulty. Despite this, two groups have recently reported measurements of lines from singly ionized zinc which allow them to determine its abundance relative to hydrogen at redshifts $z = 2.8$ and $z = 2.3$ (refs 1, 2). Thus, depending on the rate of slowdown of the expansion of the Universe, they are examining the chemical content of material which existed when the Universe was something like 15–30 per cent of its present age. In both cases, the heavy-element abundances relative to hydrogen, as measured by Zn^+, are roughly an order of magnitude down on the value near the Sun. The straightforward interpretation of these results is that nucleosynthesis in these high-redshift systems has led to the production of only about one-tenth of the heavy elements we see today, and so the objects are in an early stage in their chemical evolution.

In both studies it was possible to compare the zinc abundance with chromium, another species that is depleted onto grains, and in both cases the chromium abundance is closer to the true value than in the Galaxy As a consequence, it seems likely that these high-redshift regions are relatively dust free. If this is true in general, abundance analyses based on the stronger lines of more common elements that are depleted in a galaxy should provide reasonably reliable estimates for the true abundances. This is encouraging for those wishing to probe higher-redshift, and possibly lower-abundance, systems to obtain a fuller picture of the chemical history of material in the Universe. □

MULTIPLE SCLEROSIS

Hopeful genes and immunology

Dale E. McFarlin and Peter J. Lachmann

Although both environmental and genetic factors are believed to contribute to the pathogenesis and etiology of multiple sclerosis (MS), it is the genetic contribution which is attracting most attention in research laboratories at present, and which was the main focus of a recent workshop*.

The evidence for a genetic contribution to MS is derived from studies of the disease in families and ethnic groups. Recent population-based studies of large numbers of patients have confirmed earlier impressions that up to 18 per cent have affected family members (A.D. Sadovnick, University of British Columbia) and that there is a higher concordance in monozygotic (MZ) than in dizygotic twins (G.C. Ebers, University of Western Ontario). Also, some clinically normal MZ twins have abnormalities on magnetic resonance imaging consistent with subclinical disease. Moreover, environmental factors do not explain why the disease is absent in Hutterites residing in western Canada, a region of high prevalence (W.J. Hader, University Hospital, Saskatchewan) or why in Kuwait, the prevalence is approximately three times greater in Palestinians than in Kuwaitis (A.S. Al-Din, Kuwait University).

The epidemiology of MS is consistent with a polygenic disorder and a number of genes were discussed as possibly contributing to susceptibility Emphasis was placed on genes related to immune function because of the prevailing opinion that an immunopathologic process gives rise to the disease. Associations between MS and HLA class II molecules, particularly the DRw2 and DQw1 serotypes, are well known. Extensive analyses of HLA class II genes in MS have been conducted and a *DQβ1* gene that encodes polymorphic sequences in DR2, DR4 and DRw6 was found in 97 per cent of Norwegian patients and in 70 per cent of controls by using a sequence-specific oligonucleotide probe (F. Vartdal, University of Oslo). Another new finding was that a recently recognized DQα polymorphism correlates with the disease (R. Heard, Hammersmith Hospital). So far, however, no specific HLA class II sequence related to susceptibility or resistance to MS, analogous to that described in insulin-dependent diabetes, has been identified.

The possible role of genes other than those of the *HLA-D* locus on chromosome 6 was discussed, particularly those encoding TNF-α, TNF-β and complement components. Some products of these genes can lead to damaged myelin and secretion of TNF-β by myelin basic protein-specific T-cell clones, discussed below, correlates with the production of experimental allergic encephalomyelitis (EAE), a possible animal model of MS (L. Steinman, Stanford University). Complement activation has been implicated in the pathogenesis of MS and EAE (D. A. S. Compston, University of Cambridge), and it was suggested that genetic deficiency of late-acting complement components could be protective in populations with low frequency of MS.

Three independent groups of investigators presented new findings linking MS to T-cell receptor (TcR) genes. One study showed that haplotypes for germline V beta genes in $DR2^+$ MS patients differed ($P < 0.002$) from those in $DR2^+$ controls (W.E. Biddison, NIH). In the second study, *TcRβ* haplotypes defined by polymorphic markers were compared in MS sibling pairs, and haplotype sharing was found to be significantly more frequent ($P < 0.004$) than expected (S.L. Hauser, Harvard University). The third study reported linkage of MS to a TcRα gene polymorphism and described amplification of this gene by polymerase chain reaction (PCR) from MS brain (J R. Oksenberg, Stanford University).

The influence of genes at other loci was also considered. The previously described association between MS and genes on chromosome 14 including *GM1* and the α-antitrypsin gene were debated and now seem less convincing to some investigators (G. Stewart, University of Sydney; B. De Hooghe, University Hospital, London, Ontario). No new information on the previously reported association with *GM3* was described. Various clinical observations provoked discussion of genes related to gender: the prevalence is higher in females than males; in like-sex MZ twins, the concordance is higher in females than males, and in families in which parent to child 'transmission' occurs, the father to son 'transmission' is lower than other possibilities (Sadovnick). A resistance gene on the Y chromosome or a recessive resistance gene on the X chromosome could explain the findings, but data supporting such possibilities are lacking.

New findings from a variety of auto-

* *Genes and Susceptibility to Multiple Sclerosis*, Cambridge, 25–29 July 1989

immune animal diseases were presented, from whence a common theme with implications for MS emerged. This is that the spontaneous occurrence of autoimmune disorders, such as thyroiditis, insulin-dependent diabetes and systemic lupus crythematosus — and so, by implication MS — requires the interaction of three or more genes, one of which is usually an *MHC* gene. When fewer than the required number of genes are present, pathological abnormalities may occur in the absence of clinical disease. For example, at least three genes are required for the expression of insulin-dependent diabetes in NOD mice, but if only two are present as in NOD.H2^b congenic strain, abnormal accumulations of mononuclear cells occur in the pancreas (L. Wicker, Merck, Sharp and Dohme). Multiple genetic influences are clearly operative in experimentally induced demyelinating diseases that serve as possible models for MS, including EAE (F. Lublin, Thomas Jefferson University, Philadelphia) and encephalitis associated with coronavirus in rats and Theiler's murine encephalomyelitis virus (TMEV) in mice. A gene that confers resistance to subacute demyelinating disease in rats has been identified (H. Wege, Universitat Wurzburg). Recent experiments indicate that the demyelination produced by TMEV is the consequence of a T-cell response to a viral antigen (S.D. Miller, Northwestern University). Such immunologically mediated processes require recognition of antigen in association with MHC molecules, but in the central nervous system, MHC is expressed in relatively low amounts, if at all. This has led to considerable interest in the capacity of residual cells of the central nervous system, such as astrocytes, microglia and capillary endothelial cells, to function as antigen-presenting cells and to participate in immunopathological processes.

The findings in MS and animal models provide a clear rationale for future studies. One approach will be to define the disease susceptibility genes related to MS in greater detail. Such efforts will benefit from recently developed approaches such as 'micro-satellite' probes and the use of PCR in conjunction with specific oligonucleotide primers for the genes of interest. Assessment of multiple genes in well-characterized families will be essential. This will be laborious and progress will be enhanced by cooperation among different investigators. It was particularly encouraging, therefore, that considerable discussion, including an unscheduled evening session, was devoted to future collaborative efforts. As such genetic studies proceed, there will be parallel efforts to characterize immune reactivity in MS. Extensive studies in a few patients indicate that such findings will be complicated. For example, T-cell reactivity to myelin basic protein is heterogeneous both in terms of epitope specificity and *TcR* gene usage (J.R. Richert, Georgetown University).

Another line of investigation that received encouragement is the development of therapeutic strategies that involve immunological manipulation. Studies of EAE and immune reactivity to myelin basic protein provided the basis for five approaches affecting either T cells or antigen presentation. One is treatment with antibody to CD4. This inactivates the subset of T cells that bear this protein (H. Waldmann, University of Cambridge) and is beneficial in EAE. Another approach is the use of antibody to the TcR. Support for this approach is derived from experiments with encephalitogenic T-cell clones. In PL mice, these preferentially use Vβ8.2, and the administration of antibody to this *TcR* gene product blocks EAE (Steinman). An alternative is the use of antibody to MHC class II molecules, which suppresses EAE in some species.

Finally, there are two approaches that make use of peptides and which were explored recently in News and Views by Charles Janeway (*Nature* **341**, 482–483; 1989). In one case, the plan is to immunize with TcR peptides. Recent data indicate that encephalitogenic T cells from mice and rats share germline *TcR* genes despite difference in peptide specificity. A conserved sequence has been identified and vaccination with a corresponding synthetic nonapeptide induces resistance to EAE in the highly sensitive strain of Lewis rats (M. Howell, Immune Response Corporation, San Diego). The other possibility is to block MHC class II molecules with specific peptides. Assessment of synthetic polypeptides with single amino-acid substitutions in the nonapeptide that causes EAE in PL mice has identified one that binds with high affinity to MHC class II molecules (J. Rothbard, ImmuLogic Pharmaceutical Corporation, Palo Alto) and inhibits the induction of EAE (D. Wrath, Stanford University).

Collectively, these experiments provide an elegant demonstration that recently acquired knowledge in fundamental immunology can be used to modify an immunologically mediated disease such as EAE. This produced considerable excitement for extending such efforts to MS patients. Implicit in such reasoning is that a T cell-mediated process contributes to the pathogenesis of MS and that humans will respond in the same manner as rodents. Neither of these is yet certain. Nonetheless, it is clear that the workshop has provided the basis of a variety of new approaches for studying MS. □

DAEDALUS

Sound of silence

A PORTABLE radio or tape player with loudspeakers is essentially an offensive weapon; its chief function is to annoy other people. The socially responsible music lover uses a personal tape player driving earphones, so as to deafen himself without disturbing anyone else. Sadly, this noble intention is seldom achieved. The soft, tinny, rhythmic leakage from earphones has a unique annoyance value of its own. So Daedalus is developing a truly private listening system. His idea is to vibrate the user's eardrums directly, without ever generating any sound at all.

To couple the eardrum directly to a mechanical transducer would require the most delicate surgery, and would permanently affect normal hearing. But Daedalus recalls a magnetic ear-lacquer he once invented. Sprayed into the ears, it coats the eardrums so that they can be vibrated by an oscillating magnetic field. It was intended as the sensing component of a magnetic metal-detection system; but Daedalus now sees it as the ideal way to create an entirely private sound sensation. With his eardrums coated with ferromagnetic lacquer, the user will directly hear the audio field of a nearby induction coil, mounted perhaps on his collar or spectacle frame. Feed the coil from his personal tape player, and he will hear its music in wonderful high fidelity — all the distortions and limitations of small earphones will be eliminated. Nobody else will hear a thing. The lacquer should last for several days, until displaced by the ear's natural waxy secretion.

This splendid technology can easily be extended. The deaf-aid industry will surely welcome such a simple way of generating subjective sound, free of all the limitations of small ear pieces and the problems of acoustic feedback. Buses and aircraft will be able to radiate a music channel magnetically, and charge patrons for the use of a discreet ear-spray to listen to it. And magnetic tape recordings will become far more accessible—just wind them past your lacquered ear and hear them directly, with no electronics needed at all!

But the uses of ferromagnetic ear-lacquer should extend far beyond sound reproduction technology. Electricians could listen directly to motors, transformers and relays to diagnose their ills. They could track wiring through a house, and estimate the current flowing in it by sound alone. And health worriers could monitor the general environmental level of a.c. magnetic fields, which over time are feared to depress the human immune system. With the malign tones of overhead power lines, military radars, and badly shielded video-display terminals ringing in their ears, they could assess the hazards directly, and adopt the appropriate level of worry.

David Jones

Satellite data contamination

SIR—Strong[1] claims to have observed a global warming of 0.1 °C yr^{-1} for the period 1982–88 using satellite-derived sea surface temperatures (SSTs). His results show a much larger warming trend than other analyses of the same data[2]. Strong's analysis is in error because, during the initial two years of his analysis period, he excluded SST data when the satellite data were contaminated by the signal from the dust cloud from the El Chichón volcanic eruptions of 29 March and 3–4 April 1982. Because the dust from the El Chichón volcanic cloud absorbed some of the infrared radiation emitted by the surface and re-emitted some infrared radiation at a lower temperature, satellite measurements of the thermal emission of the sea surface gave readings in these areas that were too low.

The excluded data in this region were not randomly distributed with respect to the mean SST, but covered the region of high SST anomalies resulting from the great El Niño of 1982–83. It was precisely where record-breaking SSTs were being observed at the surface that Strong eliminated data. In fact, recognition of the intensity of the 1982–83 El Niño was delayed at the time by dependence on satellite data that did not show the warm SSTs.

Strong[3,4] used the difference between the satellite-derived SST and *in situ* data from ships and buoys as a measure of the thickness and location of the El Chichón dust cloud. It can be seen from his analyses that the *in situ* SST measurements in the region of the El Chichón dust were more than 0.4 °C higher than the satellite-retrieved values between the Equator and 30° N from April 1982 to August 1983, and were more than 1.0 °C warmer for most of this region for most of this time.

The result of excluding the contaminated satellite-derived data was to miss the warm temperatures of the ocean during the first two years of his analysis. Thus the trend in his analysis is much too large, because it starts from temperatures that are too cold for 1982–83. Omitting the data from these two years did not correct this mistake, because the temperatures for these two years were higher than the average for the next two years, not equal.

Had Strong substituted *in situ* data for the missing data in 1982–83 to get a 'blended' analysis, as is done routinely at the Climate Analysis Center[5], he would have calculated the correct trend. Indeed, he had these data available because he used them in his previous work[3,4].

Analyses of the long-term temperature record of the globe show an irregular warming during the past century (as shown in ref. 2 for example), but this warming cannot be unambiguously ascribed only to the effects of anthropogenic greenhouse gases. To separate out the competing effects of volcanic eruptions (which cause cooling for several years, and probably longer), tropospheric aerosols, and random, chaotic variations of the climate system, the actual record of climate change must be known as accurately as possible. This requires a combination of data sources, including satellite data. But when satellite data are not available, such as in 1982–83, the best available data must be used to give correct global temperatures.

ALAN ROBOCK
Department of Meteorology,
University of Maryland,
College Park,
Maryland 20742, USA

STRONG REPLIES—As mentioned by Robock, the effects of aerosol from El Chichón during the 1982–83 period have been well documented[3,6], showing extensive involvement for about 18 months over large portions of primarily the Northern Hemisphere. I also discussed the effects from El Chichón. Robock is concerned that missing grid-point data (not eliminated by me, but by the Multi Channel Sea Surface Temperature (MCSST) cloud detection procedures) in the areas where aerosol contamination was extensive could distort the data, particularly if those areas were undergoing dramatic warming from the 1982–1983 El Niño. Although many grid boxes in the 10°–30° N latitudinal band over the Pacific were void of data, most of these were during the period April–September 1982 before the development of El Niño during September 1982 along the Equator. By the time the volcanic debris migrated southward during December 1982 over the region being affected by the developing El Niño, some data were available for grid-box MCSST monthly means, although derived from fewer MCSST retrievals, despite volcanic aerosols. The missing MCSST data from the volcanic cloud, therefore, did not substantially affect the region where El Niño was developing.

The major concern is a period of negative offsets in derived MCSSTs from December 1982 to mid-1983 over the eastern and central equatorial Pacific. As Robock points out, an alternative analysis could have been performed to eliminate any possibility of contaminated MCSST data during the 1982–83 period by using a hybrid data set substituting entirely *in situ* sea surface temperatures (SSTs) everywhere for the El Chichón years.

Following Robock's suggestion, I have used monthly ship and buoy *in situ* SSTs over a grid identical to the one I used earlier[1]. These conventional data (not analyses) were then substituted for the initial 1982–1983 portion of the MCSST record. The revised short-term trends are somewhat less, but are still upward. For the 6.5-year record (January 1982 – June 1988) the rates of change are: Global = 0.08 °C yr^{-1}; Northern Hemisphere (NH) = 0.07 °C yr^{-1}; Southern Hemisphere (SH) = 0.07 °C. This compares with my previously reported global, NH and SH MCSST rates of change of: 0.12, 0.16 and 0.10 °C yr^{-1}, respectively. Using entirely conventional data these global, NH and SH rates are: 0.04, 0.04 and 0.03 °C yr^{-1}. For hybrid data spanning an updated period from 1982 to March 1989 the global, NH and SH slopes are: 0.05, 0.04, and 0.05 °C yr^{-1}, respectively; conventional global, NH and SH SST rates: 0.03, 0.04, and 0.02 °C yr^{-1}, respectively. As well as accounting better for some of the contaminated MCSST data in 1982–1983, these updated values reflect the cooling that took place over much of the Earth's oceans during 1988. So far during 1989 the tendency has been again towards higher values.

High table tales

SIR—Robert May (*Nature* **341**, 386–387; 1989) has Haldane's famous beetle story elicited by a question from Jowett. Haldane was born (in Oxford) on 5 November 1892, Jowett died on 1 October 1893, having left Oxford in September of that year. So while they could have met, they certainly did not have a conversation either at high table at Balliol, or anywhere else.

Mummified enzymes

SIR—Although it is known that many biopolymers in mummified tissues remain structurally intact, no functional evidence of an isolated protein has yet been found. The availability of a well defined air-dried mummy of a male aged 16 (±2) years, from 1200 BC[1] prompted us to search for the presence of functional Cu_2Zn_2 superoxide dismutase or its remnants. A sample

Fast protein liquid chromatography of mummified brain extract on Superose-12. The column was calibrated with BSA, horse heart cytochrome *c* and glucagon, and was operated at 0.5 ml min^{-1} at 20 °C, PBS was used as equilibration buffer. Protein elution was traced at 280 mm (A_{280}) The fractions were analysed for copper on a Perkin-Elmer Zeeman 3030 atomic absorption spectrometer. Superoxide dismutase activity was monitored using the nitro blue tetrazolium assay[2]. The reaction volume (0.5 ml) contained 0.62 mM nitro blue tetrazolium, 20 mM Tris-HCl buffer, pH 7.8, 1 mM EDTA, 0.2 % (w/v) gelatine, 50 μM xanthine, 0.18 μM xanthine oxidase and the sample. Readings were taken at 540 nm in a 10 mm light-path cell at 23 °C. SOD, relative superoxide dismutase activity.

of brain tissue taken at autopsy and stored completely dry in the presence of solid NaOH, was minced and suspended in phosphate-balanced saline buffer overnight. Using the xanthine, xanthine-oxidase-dependent nitro blue tetrazolium assay[2], we obtained unequivocal proof of a specific Cu_2Zn_2 superoxide dismutase activity in the extract; 66 per cent of the copper present in the soluble fraction could be assigned to this enzymatic activity. The presence of 1 mM EDTA did not affect this activity, but 0.1 mM cyanide completely abolished the observed inhibitory reaction. Unfortunately, the concentration of the active component was too low to be detected by nitro blue tetrazolium staining on polyacrylamide gels after electrophoresis, but fast protein liquid chromatography of the extract on Superose-12 revealed a Cu-containing polypeptide of relative molecular mass 5,000 (5kD) to which we ascribed all the activity (see figure). It is assumed that during the ageing process, considerable portions of the original 31.3kD homodimer were cleaved leaving the active core.

To the best of our knowledge, this is the first case of an enzymatically active component surviving 3,000 years of mummification. Secondary microbial infections after excavation and autopsy were excluded as a source of the superoxide dismutase activity, as no fungal or bacterial population was seen even when tissue extracts were incubated for more than 16 days. Other methods of mummification, specifically those using natron, resins, oils and especially bitumen, cause deterioration of many biopolymers. Muscle tissue samples taken from several mummies pretreated in this manner showed considerably less activity, or none at all, probably because reactions of the resin or bitumen with intact tissue proteins, converted them into catalytically inactive polymers.

Screening for cystic fibrosis

SIR—P.N. Goodfellow, commenting on the probable identification of both the cystic fibrosis (CF) locus and the most common of the recessive alleles leading to the clinical condition, advocated an immediate start to carrier screening[1]. Before prenatal screening can be implemented, I suggest that several issues have to be considered.

The defined mutant allele seems to account for about two-thirds of CF chromosomes, and hence is found in the homozygous state in about four-ninths of affected individuals[2]; these proportions may well vary in different populations. In the UK and North American populations, the frequency of affected individuals is around 1 in 2,000 so that about one affected pregnancy in every 4,500 of the screened population could be detected. The most likely strategy would be to screen one partner in each pregnancy; if he or she is a carrier, the second partner would be screened; and if both partners are carriers, prenatal diagnosis would be offered, with a view to termination of affected pregnancies.

In round terms, for first pregnancies the risk of CF would currently progress from the initial 1 in 2,000 (of which 1 in 4,500 are detectable), through 1 in 90 (1 in 140 detectable) for those screened and found heterozygous, to 1 in 4 where both partners are heterozygous (1 in 1,100 screened couples), with a residual risk of 1 in 250 where only one partner is finally found to be heterozygous for the known mutation (1 in 35 of screened couples). (The risks of not detecting an affected child are higher if whole families, rather than just the first child, are considered.) These figures will obviously be improved as further mutations are identified.

To enable this progression, informed consent to testing would be required from both partners; if screening were carried out on the first partner but consent was refused by the second, a positive test would raise the risk to a level that might produce anxiety but would not necessarily justify prenatal sampling procedures. False-negative tests (unexpected affected children), as well as unnecessary prenatal sampling, would result from non-paternity of putative fathers; the frequency of non-paternity is variable, but can be 10 per cent or higher. The timing of the tests is difficult if screening is initiated at the first hospital ante-natal clinic (around 9–14 weeks gestation in Britain), because little time is left for obtaining the second and third samples if a reasonably early termination of pregnancy is to be offered. Earlier sampling, which implies the involvement of general practitioners, would be preferable.

Prospective parents would need education and counselling to give informed consent. Education should also include the relevant medical and para-medical specialities so that accurate and timely information could be provided. Community health workers would be needed to ensure appropriate timing, the co-ordination of tests with availability of facilities and continuity of counselling. High-risk couples should be referred to clinical genetics services experienced in ensuring that appropriate counselling and social support are available; and the outcome of the programme should be regularly reviewed.

Programmes of community health education and action have been instituted for ethnic groups with high incidences of haemoglobinopathies. Coping with genetic disease in this way would be a new and major undertaking for most of the European and North American population, and the uptake is hard to predict; but screening could not be justified without this kind of integrated approach.

NEUROSCIENCE

The Neurobiology of Memory
Concepts, Findings, Trends

Yadin Dudai

What changes take place in molecules and nerve cells in our brain, when we learn and remember? How many memory systems do we have, and how are they affected by disease? Drawing from several fields of modern neurobiological research, this book describes and explains the state-of-the-art answers to the above and many other questions concerning learning and memory.

Brain Opioid Systems in Reproduction

Edited by Richard G. Dyer and Richard J. Bicknell

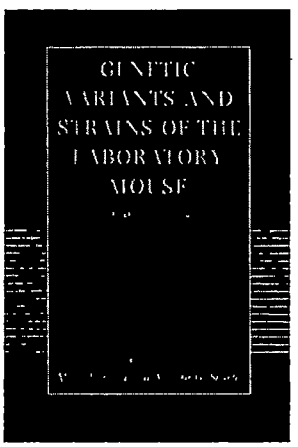
Many aspects of reproduction depend on brain signals controlling hormone secretion from the pituitary gland. Recently, opioid peptides have been shown to be essential in regulating sexual behaviour and reproduction. In this volume, experts explain the control processes.

0 19 857694 3, 379 pp., illus., 1989 £45.00

The NMDA Receptor

Edited by J. C. Watkins and G. L. Collingridge

Research into the function of the NMDA receptor has exploded in recent years. The Bristol group has organized a symposium devoted to presenting the newest information, and this is a record of the procedings.



0 19 963125 5, 200 pp., illus., paperback, IRL Press, December 1989 £25.00

Sodium–Calcium Exchange

Edited by T. Jeff A. Allen, Denis Noble, and Harald Reuter

The way a cell maintains its total calcium content is a central issue in physiology. This book introduces the reader to the role of sodium-calcium exchange in calcium homeostasis.

0 19 854735 8, 344 pp., illus., October 1989 £40.00

Genetic Variants and Strains of the Laboratory Mouse
Second Edition

Edited by Mary F. Lyon and Antony G. Searle

This is the authoritative reference for information on mouse genetic and chromosomal variants. It describes all the known genes, and features a range of genetic maps. The second edition has several new chapters, and includes full nomenclature information.

0 19 854204 6, 912 pp., illus., 1989 £90.00

FORTHCOMING

In Situ Hybridization
Principles and Practice

Edited by Julia M. Polak and James O'D. McGee

This forthcoming volume discusses basic principles and current areas of research in this topic, covering radioactive labels, autoradiography, and choice of emulsions of *in situ* hybridization; non-radioactive probes, oligonucleotide probes for *in situ* hybridization; *in situ* hybridization and the study of development; and other topics.

Migraine: A Spectrum of Ideas

Edited by **Merton Sandler and Geralyn Collins**

Leading experts here present the numerous advances made over the past two decades in our understanding of this painful illness, and discuss the position of migraine research today and its future directions.

0 19 261810 5, 336 pp., illus., December 1989 £35.00

Nicotine Psychopharmacology

Molecular, Cellular, and Behavioural Aspects

Edited by **S. Wonnacott, M. A. H. Russell, and I. P. Stolerman**

Recognition of the important role of nicotine in tobacco addiction, together with rapid advances in the techniques available to neuroscientists, has led to a great increase in research into the effects of nicotine on the central nervous system. Experts here present the leading edge of this research.

0 19 261614 5, 370 pp., illus., February 1990 £40.00

NEW EDITION

Structure of the Human Brain

A Photographic Atlas

Third Edition

Stephen J. DeArmond, Madeline M. Fusco, and Maynard M. Dewey

This is a thorough revision of the leading neuroanatomy atlas for medical, dental, and allied health students.

'The most complete and most profusely illustrated human brain atlas currently available.' **Contemporary Psychology** on an earlier edition.

0 19 504357 X, 208 pp., illus., paperback, OUP USA, 1989 £15.00

The Peripheral Actions of 5-Hydroxytryptamine

Edited by **John R. Fozard**

5-hydroxytryptamine, or serotonin, is an important neurotransmitter, and the subject of much current research. This book examines the most significant recent developments, emphasizing their potential in the design of novel drug treaments.

0 19 261683 8, 433 pp., illus., 1989 £45.00

Cajal on the Cerebral Cortex

An Annotated Translation of the Complete Writings

Edited by **Javier DeFelipe and Edward G. Jones**

This is the first English-language publication of the complete works of the great Spanish neurohistologist, Santiago Ramon y Cajal (1852–1934), on the cerebral cortex.

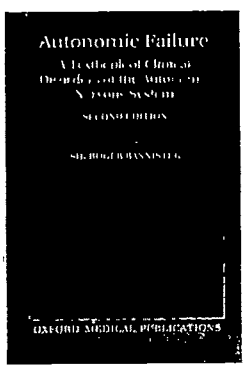
History of Neuroscience No. 1
0 19 505280 3, 672 pp., illus., OUP USA, 1989 £50.00

The Segmental Motor System

Edited by **Marc D. Binder and Lorne M. Mendell**

This comprehensive review of recent work on segmental motor systems will serve as a handy and authoritative reference to the mammalian segmental motor apparatus.

0 19 505484 9, 426 pp., illus., OUP USA, December 1989 £48.00



NEW IN PAPERBACK

Autonomic Failure

A Textbook of Clinical Disorders of the Autonomic Nervous System

Second Edition

Edited by **Sir Roger Bannister**

This new edition describes recent advances in the management of autonomic disorders in diseases such as diabetes and alcoholism, as well as in the syndromes of chronic, sub-acute and acute autonomic failure. It continues to provide a detailed, up-to-date guide to diagnosis, investigation, and treatment.

0 19 261869 5, 798 pp., illus., paperback, 1989 £30.00
0 19 261664 1, hardback, 1988 £65.00

NEW EDITION

The Genetics of Neurological Disorders

Second Edition

Michael Baraitser

Advances in DNA technology mean that some neurological disorders can now be diagnosed at prenatal and pre-symptomatic stages, causing ethical and other problems. This new edition updates the clinical delineation of genetically determined neurological disorders, and incorporates the new information about DNA.

Oxford Monographs on Medical Genetics No. 18

0 19 261814 8, 600 pp., illus., December 1989 £50.00

Neurobiology of Stereotyped Behaviour

Edited by **Steven J. Cooper and Colin T. Dourish**

Repetitive, habitual, apparently purposeless behaviour remains an enigma. It may be induced by drugs, environmentally determined, or occur in times of stress. This is the first comprehensive volume devoted to these little-understood phenomena.

0 19 852160 X, 360 pp., illus., Clarendon Press, January 1990 £40.00

Anatomical Correlates of Neuropsychological Disorders

A Neuroimaging Approach

Hanna Damasio and Antonio R. Damasio

Knowledge about neuroanatomy has played a major role in understanding the brain mechanisms behind the psychological processes. Nowhere has the role been stronger than in the study of the relation between specific areas of brain damage and changes in perception, memory, and language—the lesion method. This book explores the lesion method approach as applied to humans, reviewing recent advances and novel neuropsychological theories.

0 19 503919 X, 256 pp., illus., OUP USA, 1989 £30.00

The Neuropharmacological Basis of Reward

Edited by **Jeffrey M. Liebman and Steven J. Cooper**

This is the first comprehensive volume devoted to the major recent advances in reinforcement and behaviour. The contributors analyse current research, explain new technical advances, and outline future research directions.

Topics in Experimental Psychopharmacology No. 1

0 19 852176 6, 444 pp., illus., Clarendon Press, 1989 £45.00

Parallel Distributed Processing

Implications for Psychology and Neurobiology

R. G. M. Morris

Many neurobiologists look to current developments in the formal analysis of neural networks for a bridge between psychological and neural accounts of cognitive function. This book examines the implications of these new developments.

0 19 852178 2, 352 pp., illus., Clarendon Press, December 1989 £35.00

Sensory Processing in the Mammalian Brain

Neural Substrates and Experimental Strategies

Edited by **Jennifer S. Lund**

Discussing the neurobiology of mammalian sensory systems, contributors here explore its principles of organization, experimental modes of analysis, system components, complex neuropils analysis, and related topics.

0 19 504554 8, 366 pp., illus., OUP USA, 1989 £36.00

NEW EDITION

Oxford Textbook of Psychiatry

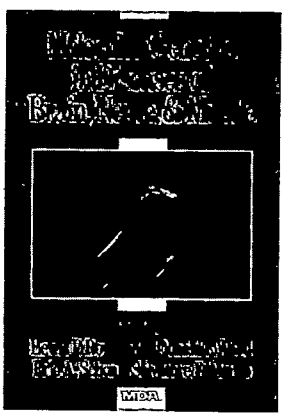
Second Edition

Michael Gelder, Dennis Gath, and Richard Mayou

This successful and established textbook provides an introduction to all the clinical topics required by the trainee psychiatrist. Throughout, the book emphasizes the clinical skills required for understanding the patient.

'Provides a well documented introduction to all the major clinical topics and sufficient references to the basic sciences to satsify the enquiring mind.' **British Medical Journal** on the first edition.

0 19 261630 7, 1,094 pp., illus., 1989 £45.00



NEW EDITION

Neurobiology of Disease

Alan A. Pearlman and Robert C. Collins

The study of the mechanisms by which diseases alter the function of the nervous system was once described as 'Neurobiological Pathophysiology'. The new title reflects a change in scope, with more information on functional and anatomical systems. This volume contains updated findings and new chapters on memory, genetic disorders, and brain tumours.

0 19 505318 4, 520 pp., illus., OUP USA, January 1990 £40.00
0 19 505319 2, paperback £25.00

Molecular Genetics in Diseases of Brain, Nerve, and Muscle

Edited by **Lewis P. Roland, Donald S. Wood, Eric A. Schon, and Salvatore DiMauro**

This book provides neurologists and others with a grounding in the concepts of molecular genetics. It surveys the neurological and neuromuscular disease that have been studied using these techniques, such as Duchenne muscular dystrophy and Huntington, Tay-Sachs, and Alzheimer's diseases.

0 19 505163 7, 490 pp., illus., OUP USA, 1989 £45.00

OXFORD UNIVERSITY PRESS

Protein Purification Methods: A Practical Approach

Edited by **E. L. V. Harris and S. Angal**

This book brings together useful practical protocols for the purification of proteins, concentrating on the uses of buffers and different means of separation (by charge, activity and size).

0 19 963002 X, 310 pp., illus., spiral bound, IRL Press, November 1989 £30.00

0 19 963003 8, paperback £20.00

Protein Purification Applications: A Practical Approach

Edited by **E. L. V. Harris and S. Angal**

A companion volume to 'Protein Purification Methods: A Practical Approach', this volume presents several common applications for protein purification methods, both large and small-scale.

0 19 963022 4, 200 pp., illus., spiral bound, IRL Press, November 1989 £27.00

0 19 963023 2, paperback £18.00

Mild Head Injury

Edited by **Harvey S. Levin, Howard M. Eisenberg, and Arthur L. Benton**

Despite extensive documentation of post-concussion symptoms following apparently mild head injury, only recently has the full magnitude of the problems these injuries cause been appreciated. This book provides the first comprehensive discussion of the subject.

0 19 505301 X, 304 pp., illus., OUP USA, 1989 £32.00

Brain Organization and Memory

Cells, Systems, and Circuits

Edited by **James L. McGaugh, Norman M. Weinberger, and Gary Lynch**

Based on the 3rd annual conference of the Center for the Neurobiology of Learning and Memory, this study features the investigations of leading researchers in psychology and neuroscience into brain organization and its role in memory, with special reference to the cerebral cortex.

0 19 505496 2, 448 pp., illus., OUP USA, October 1989 £55.00

Neural Darwinism

The Theory of Neuronal Group Selection

Gerald M. Edelman

This radically new view of the function of the brain and nervous system proposes that the nervous system in each individual operates as a selective system resembling natural selection in evolution, but controlled by different mechanisms.

0 19 286089 5, 400 pp., illus., Oxford Paperbacks, 1989 £9.95

The Emperor's New Mind

Concerning Computers, Minds, and the Laws of Physics

Roger Penrose

Is it really only a matter of time before computers can think and feel in the way the human mind now does? This intriguing book, by the brilliant theoretician Roger Penrose, puts forward his view that there are some facets of human thinking that can never be emulated by a computer.

0 19 851973 7, 480 pp., illus., October 1989 £20.00

Journals in NEUROLOGY

Experimental Neurology *A Journal of Neuroscience Research*

Editor-in-Chief

John R. Sladek, Jr. *University of Rochester School of Medicine and Dentistry, New York*

Experimental Neurology publishes the results and conclusions of original research in neuroscience with a particular emphasis on novel findings in neural development, regeneration, plasticity, and transplantation. Emphasis is also placed on basic mechanisms underlying or related to neurological disorders. In addition to original manuscripts, the journal publishes brief communications and critical reviews of important and timely topics.

A Representative Selection of Articles

Keith A. Crutcher
Tissue Sections from the Mature Rat Brain and Spinal Cord as Substrates for Neurite Outgrowth *in Vitro:* Extensive Growth on Gray Matter but Little Growth on White Matter

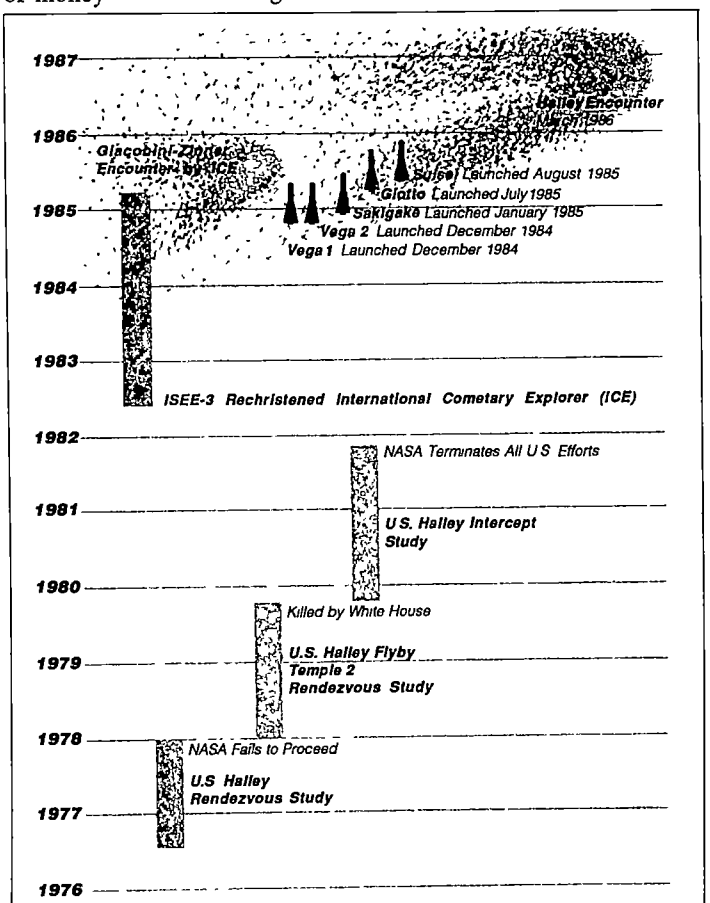
In the political orbit

John Noble Wilford

Journey Into Space: The First Thirty Years of Space Exploration. By Bruce Murray. *W.W. Norton: 1989. Pp 381. $19.95. To be published in Britain in February, £14.95.*

THE recent flight past Neptune by *Voyager 2*, the culmination of a 12-year journey of discovery in the outer Solar System, was a triumph for the brand of space exploration championed by Bruce Murray in his book *Journey into Space*. With a relatively modest expenditure of money compared to annual spending on the space shuttles, and at no risk to human life, the remotely controlled Voyager not only succeeded in visiting its primary targets, Jupiter and Saturn, but also managed to make it all the way to Uranus and, finally, Neptune. This wide-ranging reconnaissance of the planets ranks among the most exciting and scientifically rewarding achievements of the space age.



Murray has written a highly personal book. As a professor of planetary science at the California Institute of Technology, and a former director of the Jet Propulsion Laboratory (JPL), he has known the exhilaration of being in at the beginning of planetary exploration by space-craft. "What a time to be alive!" he exclaims (p.96) in recalling the heady days of preparation for the Mariner 10 mission to Mercury in the early 1970s. Commitments made in the previous decade were now bearing fruit. Hardly a year passed without the lift-off of another planet-bound craft or the arrival of more spectacular pictures from worlds that hitherto had been little more than smears of light in a telescope. Murray captures the excitement among scientists who look back fondly on those days as the golden age of planetary exploration.

Murray has also written an important and disturbing book. He takes us behind the scenes for glimpses of the conflict that has long split the American space programme into warring groups. The conflict has variously been characterized as manned versus unmanned flight, the engineers and bureaucrats of NASA versus scientists, or the powerful Houston and Huntsville space centres versus JPL, NASA's primary centre for unmanned planetary projects. Murray (who was on the losing side in most of the battles) presents a bloodied combatant's view of events.

For those who deplore the dearth of new planetary missions over the past decade, which could have been worthy successors to the durable Voyager launched in 1977, Murray's tale of frustration in dealings with the White House and NASA's own leadership should make them relieved that at least things were no worse. For those who wonder why there has been no rational, long-range US space policy since the Apollo Project, here are some of the answers. Murray does not pretend to be impartial, concluding a lengthy account of one struggle, he says that "political mediocrity triumphed over technical competence and dedication" (p.237).

As the director of JPL from 1976 to 1982, Murray found himself in the thick of the political wrangling over Galileo, an advanced spacecraft to orbit Jupiter and investigate its atmosphere, and over the various proposals for the United States to have its own entry in the international flotilla being readied for the return of Halley's comet. This was for him an ultimately dispiriting task. He came to realize he had been "leading what proved to be a strategic retreat" (p.284) from the lofty ramparts previously occupied by planetary science.

Writing the book seems to have been a cathartic experience for Murray. He is asking his scientific colleagues to understand that he tried his very best, against all odds. With the administration of Jimmy Carter, he was working with a president who, more than any other, appreciated the scientific accomplishments, but failed to exert leadership in space policy or grasp the symbolic value of space in global politics. Murray confides that in 1977 he had been asked to head NASA in the new Carter administration. Now he is left wondering if he could have made a difference. To take the job, he writes, would have cost him his scientific career, "leaving myself doomed to a purgatory of administration for the rest of my working life . . . . A high price for four years of frustration" (p.169).

Mission impossible — the fate of projects set up for the Halley encounter (taken from the book reviewed here).

After his failure to win approval for a Halley's mission from the Carter White House, Murray made one final desperate attempt with the incoming administration of Ronald Reagan. In doing so, he confesses that he stooped to a blatant patriotic appeal. How could the United States, the leader of the free world, not be a part of the main Solar System enterprise of the decade? He was rebuffed again and instead discovered that some of Reagan's advisers, notably David Stockman, director of the Office of Management and Budget, were out to abolish the entire planetary programme. Murray recalls a call in early 1981 from a budget official, who asked: "What if J.P.L. were to disappear?" (p.268).

The rest of 1981, as Murray tells it, was a critical time for the US planetary programme. Not only did he have to fight off attempts to kill Galileo, which was originally scheduled for launch in 1982, but he also had to resist Stockman's moves to pull the plug, as it were, on Voyager's life-support system. If Stockman had had his way, there would have been no money for tracking Voyager 2 beyond Saturn and thus no pictures from Uranus or Neptune.

Another adversary emerged at this time. Hans Mark, a former official in NASA and the Air Force, became deputy administrator at NASA with a hard-nosed agenda that included, the conversion of

JPL into a military research centre. In a meeting with Murray's bosses at Caltech, Mark "upbraided me" for putting the laboratory "in grave danger by obsessively pursuing planetary missions, delaying too long the inevitable move into defense work" (p.281).

A sadder but presumably wiser Murray writes of his eventual loss of innocence. Coming out of yet another meeting with unsympathetic NASA officials, he was struck with the insight: "NASA's constituency is the areospace industry! Just what my cynical university friends have been saying for years" (p.335). Scarred by these assaults, he sometimes seems to yield to the temptation to use the book to even old scores. But the real 'heavy' of Murray's story is not Stockman or Mark. It is the space shuttle.

Development of the shuttle, beginning in 1972, marked another victory for NASA's dominant group, the proponents of expensive engineering programmes for manned flight. Like many scientists, Murray had opposed the shuttle-only policy all along. Astronauts only increased costs and mission complexity, and with its diminished post-Apollo budgets the shuttle left NASA with virtually no money for anything else. Murray seldom misses a chance to take a swipe at NASA's policy. "How", he asks, "did we drift from the Apollo reality to the Shuttle fantasy and, finally, to catastrophe?" (p.24). The answer comes in his comprehensive recounting of the political machinations as NASA struggled to defend its crumbling fortress, sacrificing nearly everything for the shuttle programme, and left to fight its battles without presidential support. No one at NASA, Murray tells us, was even allowed to question the shuttle-only policy — until it was too late.

At the outset, Murray asks a second question: "How can we once again rise to greatness in space?" (p.24). His proposed answer, which he raises in the final chapters, amounts to the offer of a truce between the proponents of manned and unmanned space flight. Murray suggests the new goal for the American programme should be Mars, to be explored in greater depth by further unmanned probes and eventually by astronauts. The two factions could thus work together towards a common destination. Murray outlines the current thinking of those who advocate that Mars should be the next target, and argues for a more serious consideration of Soviet proposals that the two nations should go to Mars together. These are indeed arguments that have received too little attention from US policy makers as they seek to establish a political justification for long-range goals in space exploration. □

On manus and pes

Bernard Wood

Functional Morphology of the Evolving Hand and Foot. By O J. Lewis. *Clarendon. 1989. Pp.359. £60, $125.*

COMPARATIVE anatomy is an unusual and difficult subject, and one that is far from finished. Its practitioners require flair, but most of all they need to be experienced, observant and painstaking. These attributes are not held in great esteem at present Comparative anatomy is at best often regarded as antediluvian, science in a Victorian frock coat.

In this demanding and iconoclastic book, Lewis nails his colours unequivocally to the mast. He claims that as long as we continue to depend upon the fossil record for our understanding of evolutionary history, the interpretation of that record must be based on sound comparative anatomical knowledge. At the small risk of misrepresenting him, I believe that the author is suggesting that there has been too much 'soft' and too little 'hard' comparative anatomy. The 'soft' version consists of unsystematically consulting a few papers, old enough to be respectable, and extracting from their summaries factual items that support the particular thesis being put forward. The 'hard' variety requires both sufficient expertise to detect slipshod earlier work and the time and energy to supplement the good-quality information that does exist with one's own observations. It also involves developing a deeper comparative perspective and recognizing that the solution to a morphological conundrum among the primates might need to be sought among the muscles, tendons and bones of the monotremes.

The book is demanding because Lewis makes few concessions to his readers. The writing is clear, but the content is tough, much like the sinews it describes. There is little, if any, attempt to develop a consensus or seek a compromise, for, the author argues, there is a correct interpretation of form and that must be rigorously sought. Among the flesh and blood icons broken along the way are the practitioners of 'soft' comparative anatomy along with those who believe that it is enough to compare form through measurements and multivariate statistical analysis. Lewis's dissatisfaction with, if not disdain for, these tools is proper when they are used to compare specimens across too wide a range of morphology, but they do have a role when palaeontologists try to resolve more 'local' taxonomic problems. At first reading, there is the strong impression that the icons either all reside west of Bantry Bay or have been publishing since 1960 — it was surely no mistake on the part of the author that a paper published two decades ago is described as a 'recent' review. This impression would, nonetheless, be an unfair slur on both the author and my North American colleagues; some of us in Britain receive just as vigorous a strapping as they do. Moreover Lewis is sufficiently even-handed to admit to one or two of his own morphological indiscretions.

The book is divided into two parts, almost equal in length, one on the hand and the other on the foot. The form of bones, joints and muscles are considered in turn. A final section of each part gives an account of the relevant primate and hominid fossil evidence, but in the light of a comparative perspective that ranges as wide as prototherian mammals and extends as far back as the Triassic.

There are weaknesses, but not many of them. I would have liked to have seen more reference to good-quality behavioural studies to support functional correlations, and photographs of whole animals in typical foot and hand postures would have laid even greater emphasis on functional morphology. Contemporary research in developmental biology may also render some of the arguments about evolutionary mechanisms obsolete before long. Heterochrony and its genetic basis are treated clearly, but a little naively. But the book's strengths are manifold, and stem from the author's sheer professionalism. Not only are Lewis's own studies meticulous, but they are clearly illustrated by his own drawings. The reading is wide and the conclusions are refreshingly direct. This volume will become a classic text on how we should regard the anatomy of the organs which, along with the brain, make us human beings.

Lewis's analysis of the manus and pes is unlikely to be anatomically faultless, but his interpretations are backed up with such a weight of evidence that they must all be taken seriously. If they are to be challenged and overturned, it must be on the basis of comparative evidence of similar quality — but are there practitioners with the experience, the understanding, the meticulous dissecting technique and the diligence to do it? □

Yorick's luck

Mark Ridley

Sex and Death in Protozoa: The History of an Obsession. By Graham Bell. *Cambridge University Press: 1989. Pp. 199. £25, $44.50.*

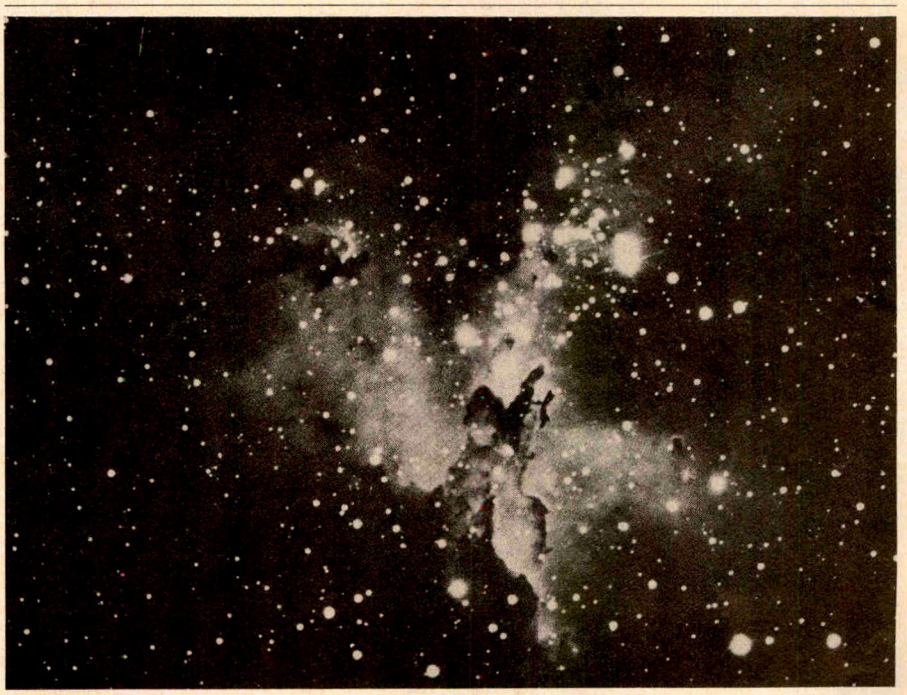
For half a century, from about 1880 to 1930, many biologists were busily trying to maintain perpetual, immortal cultures of protozoans. All the leading scientific nations contributed to this great research effort: it began with Germans, such as Engelmann and Weismann, was continued in France by Maupas and Balbiani, and the torch was passed, for the final phase, to such industrious Americans as Calkins, Jennings and Woodruff.

The main, though by no means the only, research organism was *Paramecium*. The work concentrated on 'isolate' cultures: no one doubted that 'mass' cultures with millions of protozoans could be kept going practically indefinitely. In an isolate culture, an individual protozoan is isolated and used to seed a new culture; from this culture, after a day or so, another individual is isolated and used in turn to seed a second culture, and so on. Some biologists claimed these cultures could be immortal; others that they inevitably senesced, as the organisms produced abnormalities and their fission rate declined.

There was another question. Could a senescent culture, if conditions were altered to permit sexual conjugation, be 'rejuvenated'? Again, some said yes, others no. And, according to Graham Bell, "the problem was never resolved; after fifty years it was simply abandoned". The body — or corpse — of that work has long since been buried under the dust of scholarship.

Bell's new book is a piece of grave-robbery, for he has read this old literature and has brought it to bear on our modern interests in the evolution of senescence, repair mechanisms, recombination and, particularly, sex. Incidentally, he was able to solve the old problem itself. He has located 75 experiments that can be analysed statistically. Of these, 65 show a negative relation of fission rate and time: the results (almost unknown to the experimenters) overwhelmingly confirm that isolate protozoan cultures do indeed 'senesce'. Without sex, a protozoan lineage will become extinct after a few hundred generations.

Bell also finds that sexual conjugation does revive a senescent lineage. The best experiment was by Calkins, who isolated conjugating couples from an otherwise asexual lineage of *Uroleptus mobilis*. Lines bred from the conjugants consistently out-lasted the original parental lines. Bell calls this "one of the more important experimental results of biology". It is certainly one of the more agreeable. Protozoans (in which, it should be recalled, sex is separate from reproduction) carry out conjugation in order to prolong their lives.



A number of other provocative results are conjured out of these old papers. But Bell's main concern is with the significance of the two principal results. In a chapter on senescence, he argues that decay of protozoan cultures is fundamentally different from senescence in multicellular organisms. He accepts the theory of Medawar and G.C. Williams, according to which animals like ourselves senesce because selection favours increased early survival at the expense of survival later in life. Bell believes that senescence in protozoan cultures is caused instead by the accumulation of deleterious mutations.

Reproduction in isolate cultures is parthenogenetic, by binary fission, and the accumulation of mutations thus illustrates one of the main theories of sex — the one known as 'Muller's Ratchet'. Sex, if this theory is right, exists to purge the DNA of the deleterious mutations that tend to build up in an asexual lineage. In Bell's neat image, sex is an exogenous repair mechanism. It is impossible, in a population of asexual organisms, to generate an organism with less than the present minimum number of deleterious mutations. This minimum number, moreover, tends to increase through time. If all the organisms with the current minimum number of mutations by chance all die without issue, the new minimum number will increase. Muller's Ratchet will have turned. In a sexual population, an organism with fewer deleterious mutations can be generated by recombination, and the number of mutations therefore does not tend to increase. According to Bell, "the history of isolate cultures or protozoans provides as comprehensive an illustration of the Ratchet as one could wish for".

He is probably correct, but his interpretation is not so well established as he concludes. Other theories of sex could account for the same observations. A popular theory at present suggests that sex exists because of the coevolutionary relations of parasites and hosts. It is perfectly possible that, in an isolate culture, parasites to which that particular protozoan lineage lacks resistance genes will build up. Outcrossing could then introduce the resistance mechanisms, and rejuvenate the culture. Other phenomena, such as the spindly taxonomic distribution of asexual reproduction, which Bell explains by the Ratchet, can also be explained by most other theories of sex.

These are minor criticisms. This old and forgotten literature has turned out, in Bell's hands, to contain some unexpectedly suggestive results for more modern and fundamental problems. He has evidently enjoyed exhuming the 'musty volumes'. His book is concise, elegant, non-technical and (that rare thing) a thoroughly good read. □

The Eagle Nebula (M16) — a detail taken from one of the prints in *Precision Astrophotography*, a set of 10 (11 x 14 inch) photographs by Kim Zussman. The collection, together with two others in colour (*The Finest Galaxies* and *Deep-sky Photography*), is published by Kalmbach, 21027 Crossroads Circle, PO Box 1612, Waukesha, Wisconsin 53187, USA. Price is $16.95 per set.

Starting with stars

John Lattanzio

The Fundamentals of Stellar Astrophysics. By George W. Collins II. *W.H. Freeman: 1989. Pp.494. $47.95, £37.95.*

THE theory of stellar astrophysics is naturally divided into the study of interiors and atmospheres. Collins has provided a convenient introduction to both subjects in the one text, aimed at first-year graduate students or advanced undergraduates. The book contains a thorough index, and provides a list of references and sources for further reading that will act as an excellent point of entry to the more advanced literature.

The text is divided into two parts, the first of which deals with stellar interiors. Unfortunately, the opening chapter contains a great deal of statistical mechanics. Although this material is clearly essential to the development of the subject, it may seem an anti-climax to the student impatient to deal with stars and an appendix would have been a better place for it. Collins gives appropriate attention to scaling arguments to familiarize students with the techniques, and his selection of theorems from Chandrasekhar's *An Introduction to the Study of Stellar Structure* is excellent. I feel that the section on nuclear energy generation is too brief, though it would serve as an introduction to the definitive treatment to be found in Clayton's *Principles of Stellar Evolution and Nucleosynthesis*.

Unexpected inclusions are the chapters on relativistic stellar structure and the structure of distorted stars. To my mind, however, the former would have been better omitted in favour of more detail in other sections. The final chapter of this part, which deals with pulsation and oscillation, seems to have been introduced for completeness. Ideally the stellar-evolution chapter would have mentioned variable stars (where they are seen in the Hertzsprung–Russell diagram, and how their evolution puts them there), and this chapter would then have been the necessity that it is.

Moving on to stellar atmospheres, Collins derives the equations of radiative transfer and illustrates various approximations which enable their solution. He then discusses the interaction between the gas and the radiation field. The chapter that should then be the reward for these toils, which is entitled "Construction of a Model Stellar Atmosphere", is somewhat disappointing because no example is provided.

The next two chapters deal with the formation and shape of spectral lines. Collins then looks at departures from local thermodynamic equilibrium, and concludes with an account of complications which exist in real stars (stellar winds, for example) but which have been ignored in the standard theory.

More diagrams would have been appropriate (the account of stellar evolution, for example, contains but two HR diagrams), as would some example models of stellar interior and atmospheres both as illustrations of the concepts described in the text and to show the student the rewards of learning the physics and doing the calculations. Problems are given at the end of each chapter, and they cover a wide variety of styles. Some require a stellar interior code or an atmospheres code for their completion! It is a pity that there is no section on the growing field of stellar seismology — future students of stellar astrophysics will be expected to be conversant with the subject.

These are minor criticisms of an otherwise thoroughly good book. An instructor could choose material from the text to highlight certain areas, and as a whole it forms a sound beginner's course for those wishing to specialize in stellar astrophysics. □

Out of this world

Michael Rowan-Robinson

Encyclopedia of Astronomy and Astrophysics. Edited by Robert A. Meyers and Steven N. Shore. *Academic: 1989. Pp.807. $49.95, £31.50.*

THE reader turns to an encyclopaedia when he or she is looking for detailed information about an unfamiliar topic. These days science is so specialized, and its practitioners are forced to be so narrow in their professional interests, that even in a scientist's own field a high proportion of topics will come into that category. So there is every reason why astronomers (and others) need a book such as the *Encyclopedia of Astronomy and Astrophysics*.

There are two conditions that an encyclopaedia has to satisfy. The first is that the entries must be satisfyingly packed with useful facts and information; the second is that the encyclopaedia must give in total a reasonably comprehensive survey of the area being considered. Many of the entries in the present offering satisfy the first of these requirements, especially where the topic is fairly narrowly defined and is discussed by recognized experts. "Infrared Astronomy" (by Robert Gehrz, Gary Grasdalen and John Hackwell), "Neutrino Astronomy" (Raymond Davis Jr), "Stellar Structure and Evolution" (Peter Bodenheimer) and "Supernovae" (David Branch), to pick just a few, are both interesting and authoritative.

The same cannot be said of the many entries supplied by one of the editors and those dealing with topics that are just too broad (astrophysics and cosmology, for example). These just read like fillers and do not provide enough information in the form that an encyclopaedia-reader seeks. Perhaps this compilation reveals its genesis a bit too readily. About half of the entries (generally the better half) were part of an earlier *Encyclopedia of Physical Science and Engineering*. They can be identified because they were written around 1985 and contain no reference to anything later than that. The rest of the entries have been, well, cobbled together to try to give some kind of broader coverage of astronomy. So instead of getting an up-to-date survey of the whole of the subject by specialists, we have reprints of good but not very recent articles on some topics, together with more recent, but not very inspiring, articles on others (I except the entries dealing with Supernova 1987A here).

I am no expert on many of the subjects covered in the book, and (like most encyclopaedia users) have dipped into it here and there rather than attempting to read it from cover to cover. So I cannot vouch for its overall accuracy or otherwise. Still, Arno Penzias and Robert Wilson will be amused to find themselves described on p.174 as "engineers" who "detected a microwave background coming from all directions in space into a communications antenna they had designed and built for Bell Laboratories". American chauvinism enters into the section on space infrared facilities (p.9), where the US–Dutch–British IRAS satellite is described as the "highly successful NASA IR Astronomical Satellite"; likewise, in a list of future missions, the US SIRTF mission (which is yet to be approved and funded) is described but the European Space Agency's Infrared Space Observatory (ISO, which is now being built and is due for launch in 1993) is not mentioned.

I expect I will find myself using this encyclopaedia; there is a lot of good material here. But it is a pity that the publisher and editors didn't approach their task with a bit more integrity and give us a compilation of more uniform quality. □

Brain Dynamics

Progress and Perspectives

1989. XIX, 547 pp. 206 figs., some in colour. 17 tabs. (Springer Series in Brain Dynamics, Vol. 2) Hardcover DM 248,–
ISBN 3-540-50867-8

This book takes a look at the fast-moving field of the dynamics of brain function. Topics such as EEG analysis and event-related potentials and their application in cognitive and clinical studies are discussed in detail, while special emphasis is also placed on chaos in brain function and the dynamics of evoked rhythmicities.

C. L. Veenman, D. Crzan, H. Kern, M. Rickmann, P. Wahle, P. van Mier

The Anatomical Substrate for Telencephalic Function

1989. Approx. 120 pp. 74 figs. (Advances in Anatomy, Embryology, and Cell Biology, Vol. 117) Softcover DM 110,–
ISBN 3-540-51229-2

Based on the thesis that the purpose of the telencephalon is to enable an animal to make decisions in new situations, the authors propose a model for the performance of this function based on the combination of a selection system with a sensory-motor system. The elements of the model were studied in *Xenopus laevis*.

D. M. Goodwin, Palo Alto, CA

A Dictionary of Neuropsychology

1989. VI, 330 pp. Hardcover DM 80,–
ISBN 3-540-97123-8

This volume is a cross-referenced, alphabetical listing of terms, common medical abbreviations, diseases, symptoms, syndromes, brain structures and locations, and test instruments used in neuropsychology and their neuropsychological interpretations.

A. Hartmann, University of Bonn;
W. Kuschinsky, University of Heidelberg (Eds.)

Cerebral Ischemia and Calcium

1989. XIV, 586 pp. 187 figs. 73 tabs. Hardcover DM 240,–
ISBN 3-540-50970-4

This is the first book to focus specifically on calcium metabolism and cerebral ischemia. Experts examine information on the pathophysiology of cellular events, the damage caused by excitotoxic substances, and the effects of calcium antagonistic drugs as measured in experimental animals.

Prices are subject to change without notice.

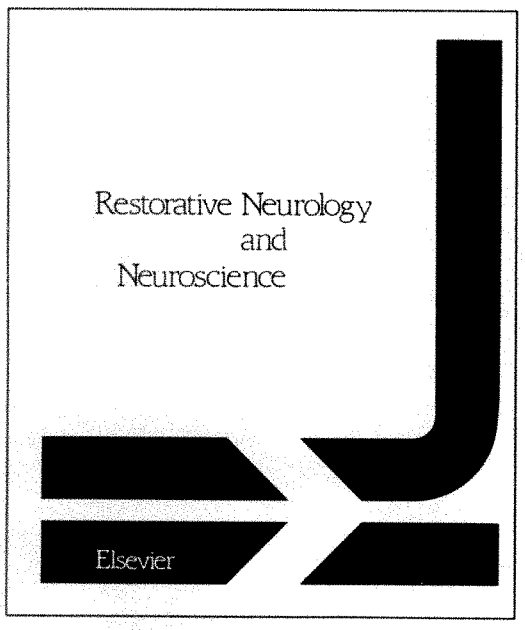
New Elsevier Journals

Discussions in Neuroscience

Now published by **Elsevier Science Publishers** for the Foundation for the Study of the Nervous System (FESN)



Series Editor: **P.J. Magistretti**, *University of Lausanne.*

* high quality monographs and edited proceedings on the most topical areas in neuroscience
* the very latest developments and research progress in neuroscience, carefully edited into a pleasant, readable form
* of invaluable interest to neuroscientists, neurologists, physicians, in addition to researchers, students and non-specialists whose primary research interests are outside the field of neuroscience
* written by leading neuroscientists; headed by a distinguished Advisory Board
* illustrations of excellent quality and clarity (often in full colour)
* the only review/monograph journal in the field with this broad appeal

Subscription Information:
1989: Volume VI (4 issues per year) Price: Dfl.65.50/US $30.00
1990: Volume VII (4 issues per year) Price: Dfl.68.00/US $32.00
Prices include postage and handling **ISSN 0254-8852**
*The US $ price is definitive. Individual copies can be purchased separately and examination copies are available for possible adoption for course use - **please write for further details.***

Restorative Neurology and Neuroscience

Editor-in-Chief: **D.G. Stein**, *Restorative Neurology and Neuroscience, The Graduate School, State University of New Jersey, Rutgers, Hill Hall, Newark, NJ 07102, U.S.A.*

Scope and Purpose: Papers relating the plasticity and response of the nervous system to accidental or experimental injuries or interventions, transplantation, neurodegenerative disorders, and experimental strategies to improve regeneration or functional recovery will be considered for publication. Experimental and clinical research papers adopting fresh conceptual approaches are encouraged.
The overriding criteria for publication are novelty, significant experimental or clinical relevance, and interest to a multidisciplinary audience.

Types of Papers: * Full-length Papers
*** Short Communications * Review Articles**

Manuscripts, in the English language only, should be submitted in quadruplicate to the Editor-in-Chief, Dr. D.G. Stein, at the address shown above.

Subscription Information:
1989/90: Volume 1 (1 volume in 6 issues)
Price: US $165.25/Dfl. 360.00 plus US $12.00/Dfl. 26.00 postage and handling
ISSN: 0922-6028 *The Dutch Guilder price is definitive. A personal rate is available on request from the Publisher*

Neuroscience from VCH

von Seelen, W. /Shaw, G. /Leinhos, U.M. (eds.)
Organisation of Neural Networks

Structures and Models

1988. XIV, 455 pages with 79 figures, 3 in color and 14 tables.
Hardcover. £ 49.95. ISBN 3-527-26715-8

This volume contains papers on the theoretical analysis and modeling of brain functions, mainly of higher vertebrates. Furthermore, reviews, which provide the necessary background information on the models described, are given so as to allow a larger circle of readers insight into theoretical neuroscience. An introductory article facilitates classification of the contributions for the reader less familiar with this fascinating scientific discipline. A "summary statement" sketches a scientific-historical map of theoretical neuroscience, assigning each author of a paper to a "site" and describing future trends of development of this discipline.

NETWORK

Computation in Neural Systems

Edited by *Daniel J. Amit, Racah Institute, Jerusalem*

Executive Board

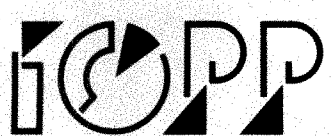
Dana Ballard (*Rochester*)
Klaus Hepp (*ETH, Zurich*)
John Hopfield (*Caltech*)
Ralph Linsker (*IBM, New York*)
Larry Jackel (*Bell Labs, Holmdel*)
Daniel Lehmann (*Jerusalem*)
Richard Morris (*Edinburgh*)
Edmund Rolls (*Oxford*)
Allen Selverston (*California*)
David Willshaw (*Edinburgh*)

The first genuinely interdisciplinary journal in neural networks, providing a forum for integrating theoretical and experimental findings across relevant interdisciplinary boundaries

The intention is to make accessible to neurobiologists, cognitive scientists and engineers the analytical methods and results of physicists, mathematicians and computer scientists. Similarly, the rapidly accumulating empirical data in the biological, cognitive and technical areas will be made available to theorists in order to stimulate a synthesis or provoke new models. NETWORK coverage will include: experimental neuroscience with reference to underpinning or manifesting network mechanisms; physics; computer science; and applied mathematics and engineering concerning models (feed-forward networks, attractor networks, cellular automata, etc) which aim to synthesize the biological results.

NETWORK will publish contributed Papers and Letters, commissioned reviews, commentaries and discussions and suggested cross-disciplinary reading. NETWORK has a unique refereeing system whereby each Paper and Letter is assessed by an Executive Board Member for its suitability for inter-disciplinary reading. Papers will be sent to two referees in the main discipline for technical refereeing, while Letters will be seen by one technical referee to ensure rapid publication.

Subscription Information



NETWORK will be published quarterly from January 1990, with the following issues appearing in April, July and October. For subscription details and to receive a free specimen copy on publication, please contact:

Journals Marketing Department
IOP Publishing Ltd.
Techno House
Redcliffe Way
Bristol BS1 6NX

STIMULATING NEUROSCIENCE

Trends in Neurosciences (TINS) is the essential monthly review journal in the expanding field of neuroscience. From cell and molecular biology to neural networks and thought itself, TINS provides readers with a clear picture of the latest progress in unravelling the complexities of nervous system function.

Each month, TINS publishes a unique blend of features and reviews commissioned from the leading experts in each field. These sections, together with research news, perspectives, techniques, letters and book reviews, keep neuroscientists up-to-date across *all* areas of neuroscience research.

The most popular neuroscience review journal around, TINS is essential reading for researchers, lecturers and students alike!

TINS is just one of the eight TRENDS review journals from Elsevier. The others cover biochemistry and molecular biology, biotechnology, ecology and evolution, genetics and development, immunology, parasitology and pharmacology.

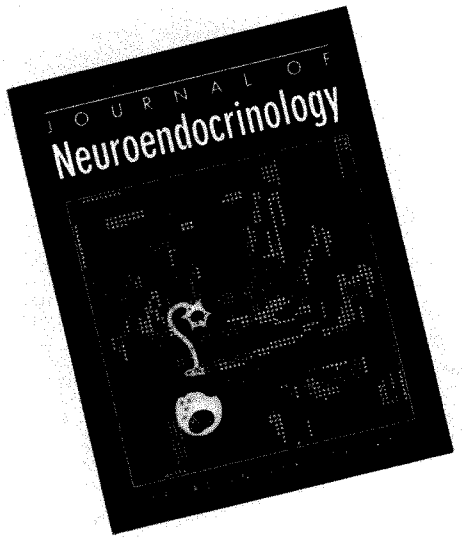
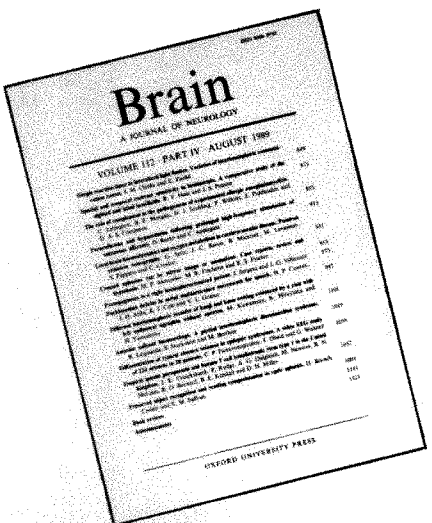
OXFORD JOURNALS



FREE SAMPLES AVAILABLE

THE EUROPEAN JOURNAL OF NEUROSCIENCE

Editor: **R. W. Guillery,** *University of Oxford*



Due to the success of its first year of publication, this journal is increasing its frequency to monthly in 1990. This will enable it to provide even more comprehensive coverage of the rapidly developing neuroscience field in its broadest definition.

JOURNAL OF NEUROENDOCRINOLOGY

Editor: Stafford Lightman, *Charing Cross and Westminster Medical School, London*

The *Journal of Neuroendocrinology* publishes timely papers dealing with the newest ideas, knowledge and technology in endocrine-related neuroscience. In an extremely rapidly changing field, the *Journal of Neuroendocrinology* has the versatility to develop with the subject by being responsive to those changes. The journal covers molecular biology, cell biology and biochemical studies, developmental studies, molecular embryology and genetics, general systems, receptor and messenger systems, new technology for neuroendocrinology, behaviour, electrophysiology, ion channels and clinical and anatomical aspects of neuroendocrinology.

BRAIN

Editor: **P. K. Thomas,** *Royal Free Hospital Medical School, London*

Brain is the leading journal of neurology. It publishes original papers in clinical neurology and related disciplines, and in the basic neurological sciences where they are relevant to clinical problems. Founded in 1877, it has published many papers which have subsequently become classics in the field.

Comprehensive sonar imaging of the Easter microplate

R. C. Searle[**], R. I. Rusby[*†*], J. Engeln[‡], R. N. Hey[§], J. Zukin[‖], P. M. Hunter[*], T. P. LeBas[*], H.-J. Hoffman[¶] & R. Livermore[#]

Recent GLORIA and SeaMARC II sidescan sonar surveys have imaged virtually the whole of the Easter microplate, and revealed unprecedented detail and complexity in its tectonic fabric and history. There is clear evidence of rapid microplate rotation, of rapidly evolving plate boundaries and of complex deformation near the northern and southern microplate boundaries.

THE Easter Microplate is about 400 km across, and lies between two roughly parallel arms of the East Pacific Rise (EPR); these are conventionally called the East and West Rifts, although morphologically they include both ridges and rifts. It is bounded to the west and east by the Pacific and Nazca plates (Fig. 1).

The microplate was first recognized from the patterns of seismicity, topography and magnetic anomalies[1-3]. These suggested the presence of a doubled spreading axis, whereas the northern and southern boundaries were thought to be transform faults[4]. Magnetic lineations near the East Rift fan southwards, implying that its spreading rate increases from north to south[1]; the spreading rate on the West Rift then should decrease from north to south. The varying rates on the two rifts should be associated with clockwise rotation of the microplate, making the southern transform boundary transtensive (or 'leaky') and the northern one transpressive[5]. Earthquake focal mechanisms confirm that the East and West Rifts are spreading centres, but show that the northern and southern microplate boundaries are characterized by a mixture of extension, strike-slip and compression[2,3,5].

The microplate may have formed when the East Rift developed by northward extension of the southern EPR across a pre-existing, left-stepping transform fault at about chron 2A (3 Myr)[4-6]. Since then the East Rift has continued to propagate northwards and should have caused the northern boundary of the microplate to migrate with it[5]. The East Rift may eventually supplant the West Rift altogether[4].

Hey *et al.*[7], using reconnaissance SeaBeam data, disputed the fanning interpretation because fanning is not observed to the east of the East Rift, and they suggested that the obliquity of magnetic anomalies was mainly the result of tectonic rotation[8] by several rifts propagating[9] along the eastern spreading centre[10].

Further SeaBeam[11,12] and SeaMARC II[13] work has revealed more detailed structure, mainly of the northern and southern boundaries and their triple junctions with the East Pacific Rise. In particular there is a strong E-W feature at 23° S which was taken[7,11,12] to be the northern microplate boundary, in spite of a cluster of earthquakes[5] about one degree farther north.

These studies have contributed to a reasonable general understanding of the microplate, but the controversy over the fanning and propagating rift models of the East Rift remained unresolved. Also, there was still uncertainty about details of the structures of the triple junctions and much of the West Rift, about a possible extension of the microplate north of 23° S, and about the structure and history of the microplate interior. In October-November 1986 we conducted a GLORIA survey of the microplate to address these problems. We have combined the data with the sidescan images from the 1987 SeaMARC II survey[13] to produce a sidescan mosaic that covers almost all of the microplate (Fig. 2).

Microplate boundaries

We identified the microplate boundaries (Fig. 1, 2) using the sidescan data, together with magnetic and bathymetric data collected concurrently with GLORIA or available from the World Data Center, Boulder, Colorado. Young sea floor was inferred from high acoustic backscatter which indicates a high proportion of unsedimented rock; in addition, spreading axes were inferred from their characteristic magnetic and bathymetric signatures and fault patterns. We recognized propagating rifts by their V-shaped pseudofault patterns and by the presence of rotated spreading fabric[8]. We identified transform and thrust faults by their fault patterns and topographic signatures.

One of our most important findings is that all of the microplate boundaries are evolving rapidly. We have confirmed the presence of a known propagating rift[10] on the East Rift and identified two more along each of the East and West Rifts (Fig. 1). Each of these has propagated to the inside (that is, the microplate side) of its respective 'doomed' rift. Because the absolute direction of ridge 'jumping' is opposite on the two sides of the microplate, the rifts cannot be jumping towards a hotspot unless it is located within the microplate. However, the propagation is tending to minimize the size of the microplate (which may help it to rotate more easily against the compressive constraints from the major plates at its northern and southern borders), and also tends to minimize the total length of the microplate boundary and therefore probably also the total energy dissipation. An important corollary is that the time-averaged accretion of the West and East Rifts is asymmetric (slower on the microplate than on the major plates), even though instantaneous spreading may be fairly symmetric.

Further evidence for rapid boundary evolution is seen in the three transforms of the West Rift. At none of these is a strong fracture zone preserved far beyond the actively slipping section, implying that the transforms formed relatively recently. Where short fossil traces are seen (most notably at the western end of the 23° S transform) they strike obliquely to the current slip direction, implying rapidly changing relative motions.

At the northern end of the East Rift (23° S) the axis is located in Pito Deep[11,12]. Between there and the propagating rift tip near 23.5° S we cannot identify the axis unambiguously. At

* Present address: Department of Geological Sciences, University of Durham, South Road, Durham DH1 3LE, UK.

23.3° S, acoustic backscatter, bathymetry and magnetics are all consistent with its occupying a highly asymmetric position in a graben at 111.87° W, although it could be up to 40 km farther east.

On the West Rift the axis south of the propagating rift at 25.3° S seems to be a simple ridge as far as 26.4° S[11]. From there Francheteau *et al.*[11] suggested that it is offset eastwards through a series of grabens into the southern margin of the microplate (Orongo fracture zone) at 26.8° S. The GLORIA and SeaMARC data, however, suggest a spreading axis (high backscatter accompanying fine, closely spaced lineaments approximately normal to the spreading direction) extending south-eastwards to 26.8° S, 114.9° W, through a gap in the 2,000 m ridge that bounds the south side of the south-west rift. We think this is either the active tip of the south-eastward propagating West Rift, or one that was recently abandoned as the extension jumped eastward to the location favoured by Francheteau *et al.*

The northern and southern microplate boundaries (Pito and Orongo fracture zones[11]) are complex structures subject to both shear and compression[5]. Short segments adjacent to the divergent eastern and western boundaries may be pure strike-slip structures[11], but over most of their lengths they seem to be complex transpressive zones, often with substantial relief[7,11], and possibly comprising en echelon thrust blocks, particularly in the north[12]. Our data confirm this, and in addition show Orongo fracture zone to be associated with NW-SE striking faults that may be oblique normal faults similar to those seen in some Atlantic fracture zones and indicative of broadly distributed shear[14,15].

The sidescan data confirm the existence of a large overlapping spreading centre[12] at the southern end of the East Rift, but reveal a confused zone of poorly defined tectonic fabric between it and Orongo fracture zone to the west. The precise position of the southern triple junction is still not clear, though it is probably near or south of a line joining Orongo fracture zone and the overlapping spreading centre[12].

At the northern triple junction, our data confirm a transform trending 088° to the west of the EPR, and a lineament of similar trend to the east. This cannot be a pure ridge-fault-fault junction[7,11] however, because two colinear transforms are inconsistent with known[16] or plausible Pacific-Nazca-Easter motions: there must either be another plate or deformation of at least one of the known plates (Fig. 3).

We see such deformation in the Nazca plate adjacent to the northern edge of the microplate. The EPR-parallel spreading fabric here trends almost due north, 10° anticlockwise from the normal to the predicted[16,17] Pacific-Nazca spreading direction. Moreover, the spreading rate on the EPR between 21° S and 23° S is less than predicted[16]. The difference implies generally northward compression in the corner of the Nazca plate between the northern EPR and the microplate, which is also the sense of predicted[5,16] Easter-Nazca motion there. This part of the Nazca plate may thus be in the process of being incorporated into the Easter microplate (Fig. 3).

A cluster of compressive earthquakes between 22° S, 114° W and 23° S, 112° W was thought to mark the site of this deformation[5]. The GLORIA and SeaMARC data show a line of en echelon E-W faults associated with large ridges, which we interpret as thrust blocks. Several of these are also sites of dextrally curving spreading fabric of the type normally found at dextral-offset transform faults[14], suggesting that a component of shear is also present.

Microplate interior

In the microplate interior both the overall level of acoustic backscattering and the general trends of tectonic lineaments are highly variable. It is possible, however, to define domains tens of kilometres across within which these features are much more uniform. Generally such domains have sharp edges, across which both the backscatter level and the strike of lineaments change abruptly. Within each domain the tectonic lineaments are straight, parallel and closely spaced, and we interpret most of them as relict spreading fabric. This pattern might indicate that the microplate was built up from many independently moving smaller blocks. A simpler explanation is that most of the domain boundaries are pseudofaults, and that the domains are small blocks of differently aged lithosphere that have been transposed and rotated[8,9] by propagating rifting. Part of our current work is directed towards reconstructing this complex evolution.

The most obvious domain boundaries are the two inner pseudofaults from the propagating northern tip of the East Rift and southern tip of the West Rift. The former curves south-westwards across the microplate from near 23.5° S, 112° W to 25° S, 115° W. At its northern end there is a sharp contrast in the acoustic backscatter across it, reflecting a discontinuity in the age of the sea floor. This contrast diminishes south-westwards as the sea floor on both sides ages and collects more sediment. By comparison with nearby areas traversed by GLORIA outside the microplate, we infer that the age contrast

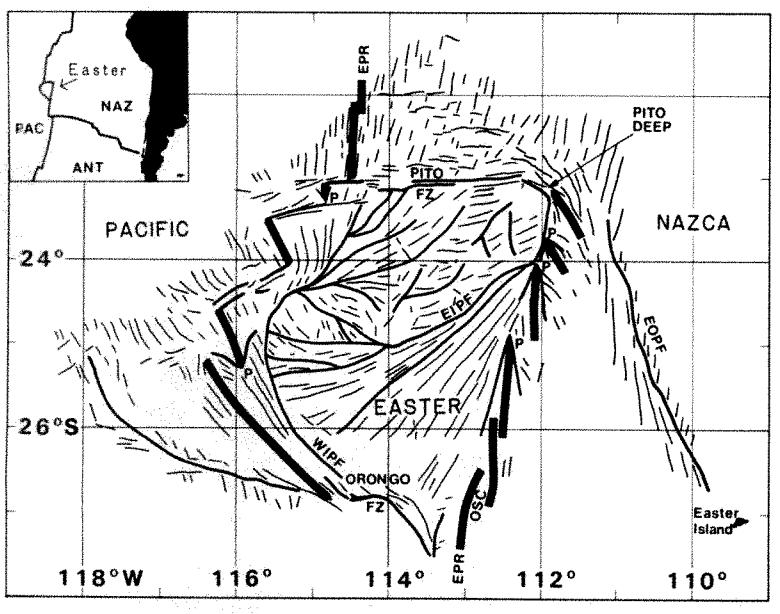

FIG. 1 Simplified tectonic interpretation of Easter microplate based on GLORIA and SeaMARC II sidescan sonar data (see Fig. 2). Heavy lines show plate boundaries. Medium lines mark pseudofaults and other discontinuities in crustal accretion. Light lines are representative fault scarps of the tectonic spreading fabric. P indicates a propagating rift tip; WIPF, EIPF and EOPF are the West Rift inner and East Rift inner and outer pseudofaults, respectively; FZ indicates a fracture zone; OSC indicates an overlapping spreading centre.

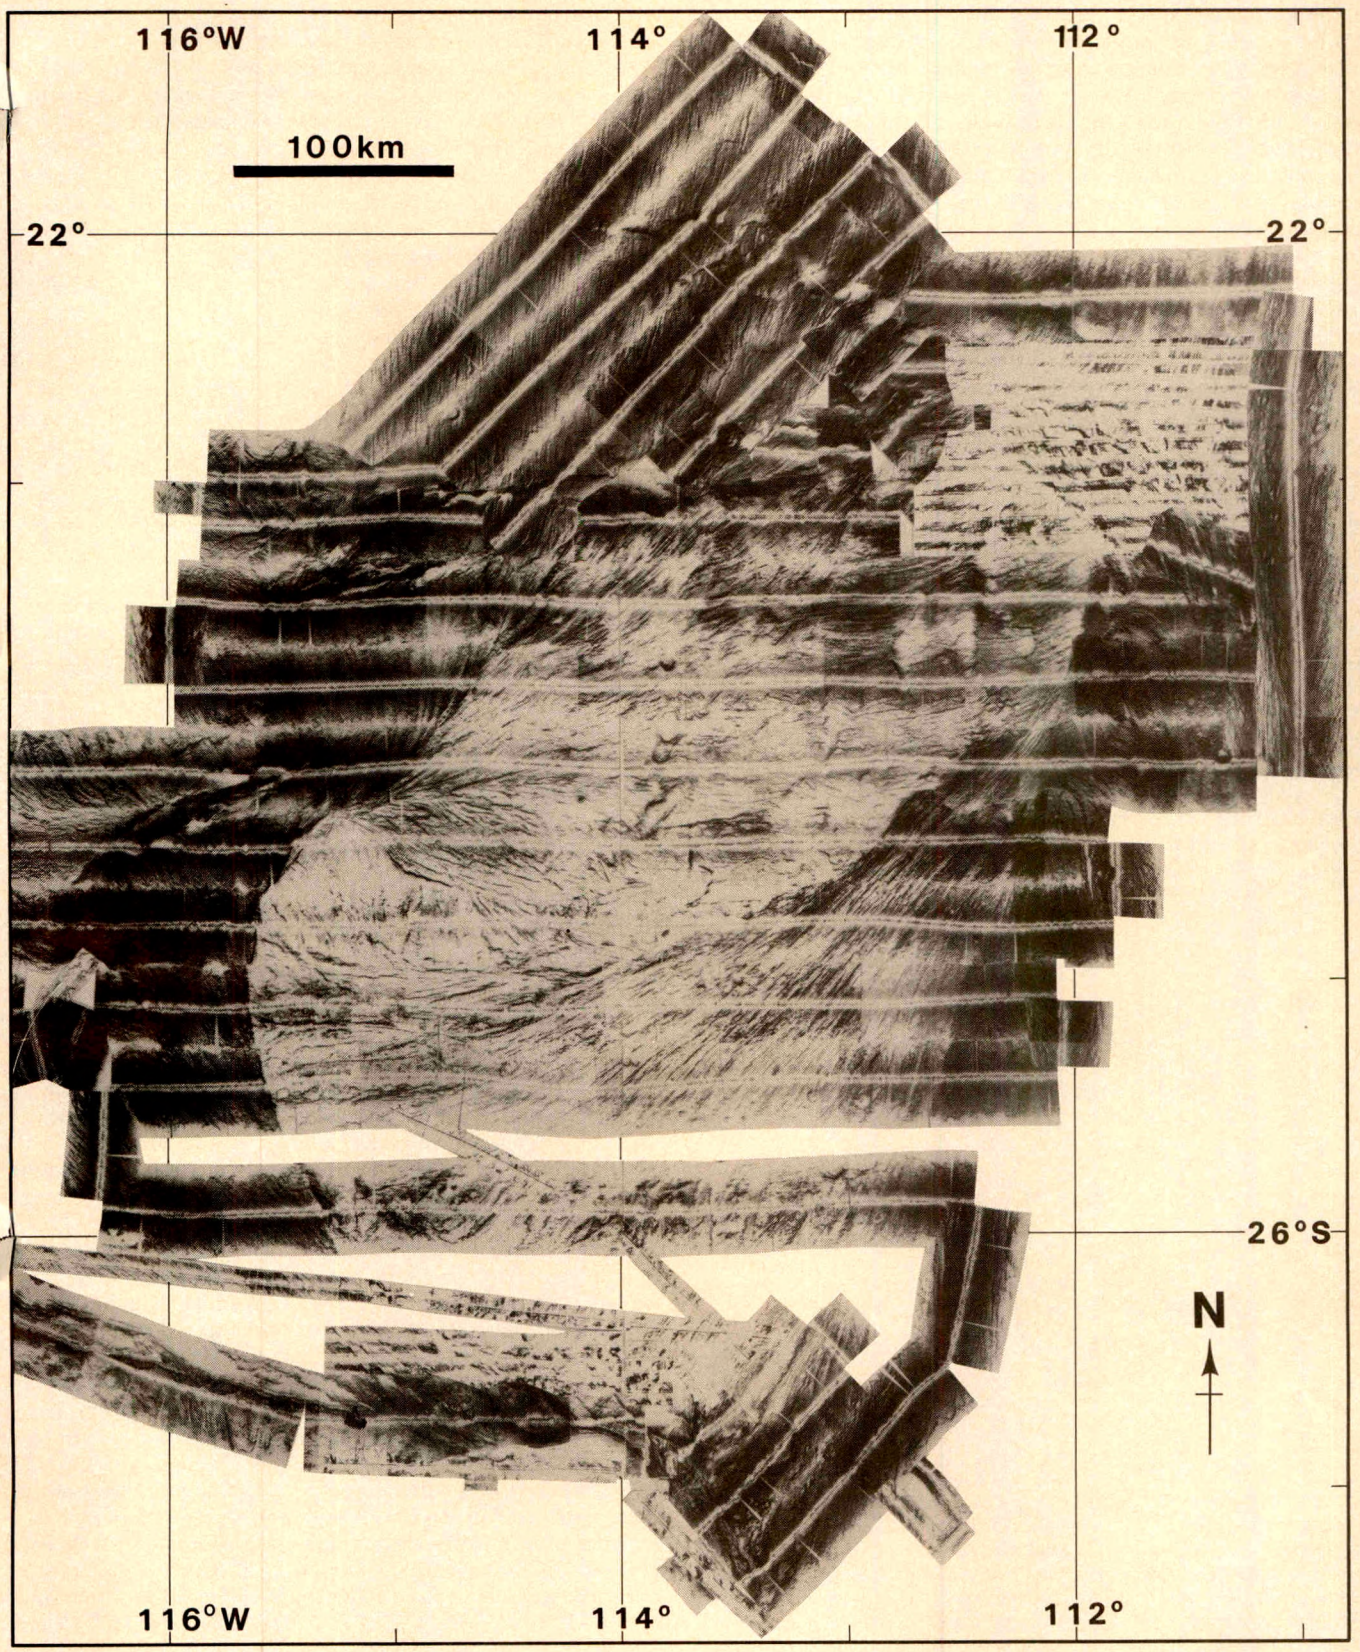

FIG. 2 Sidescan sonar mosaic of Easter microplate. Most of the area is covered by GLORIA data (40-km-wide swaths). SeaMARC II sidescan data[13] (10-km-wide swaths) are used to provide complete coverage of the area around Pito Deep[11] (north-east corner of microplate boundary) and the southern end of the south-west rift, and to partially fill other areas of incomplete GLORIA coverage. Darker tones show stronger acoustic backscattering, which usually indicates less sediment cover and therefore younger sea floor. Data have been digitally processed to correct for geometric distortions, to equalize the effective gain at different ranges, and to remove line dropouts.

at the northern end of the eastern inner pseudofault is several million years. There is a marked change in strike of the tectonic lineaments across the pseudofault, approaching 90° in places.

The most dramatic feature of the sonar mosaic is the very sharp, curved boundary between high and low backscattering at what we interpret as the inner pseudofault of the West Rift, just to the east of its axis. The evidence of an age discontinuity across this feature, combined with the continuously varying angle between it and the West Rift spreading fabric, and its southwards approach to the West Rift axis, indicate that this is a pseudofault. Magnetic anomalies and the backscattering contrast suggest that it is younger than its eastern counterpart. This evidence of relatively recent propagation of its tip, and the existence of two other propagators on the West Rift, suggest that it is less moribund than has sometimes[4] been thought.

Between the East Rift's inner pseudofault and its current spreading axis, the spreading fabric displays a fanned pattern, at least to first order. A few pseudofaults produced by the other propagating rifts along the East Rift can be inferred, but their expression is quite subtle. The inner pseudofault of the 25° S propagator[10] is revealed between 25.0° S and 25.5° S by a backscatter contrast and a 10° change in strike of the spreading fabric across it, but generally the others can be detected only by subtle (<10°) changes of strike. Thus, although the passage of propagating rifts other than the East Rift tip might account for some of the tectonic rotation of the East Rift spreading fabric and magnetic anomalies, the majority seem to have been produced as simple fanning caused by the continuously changing spreading rate along the rift.

North and west of the East Rift inner pseudofault, the microplate interior is much more complex, and although individual domains can still be recognized, the changes between them are less consistent. The oldest part of the microplate appears to be near 24.5° S, 115.5° W. It has the lowest acoustic backscattering, and its tectonic fabric is the least clearly preserved; both of these features indicate thick sediment cover. The 3.5-kHz records over the area indicate sediment thicknesses of ~10 m. Immediately to the north-east of this domain is a fan of lineaments pointing west. This may be a relict propagating rift.

The West Rift inner pseudofault becomes less clear north of this domain. Possibly the relatively recent southward propagation of the West Rift tip began about here, perhaps at the 24.5° S transform. In the north-west corner of the microplate the currently active 23.5° S transform seems to give way eastwards to a succession of NE–SW-trending fabric, the history of which we have not yet deciphered.

The tectonic fabric in the north-east corner of the microplate runs almost E–W. It is interrupted in places by N–S trending 'discordant' zones, which are generally characterized by topographic ridges and curving offsets of the tectonic fabric (such as that near 23.5° S, 112.5° W). In some ways this area resembles the deforming corner of the Nazca plate due north of the microplate, but rotated through 90°, the N–S discordant zones being analogous with the E–W thrust features farther north.

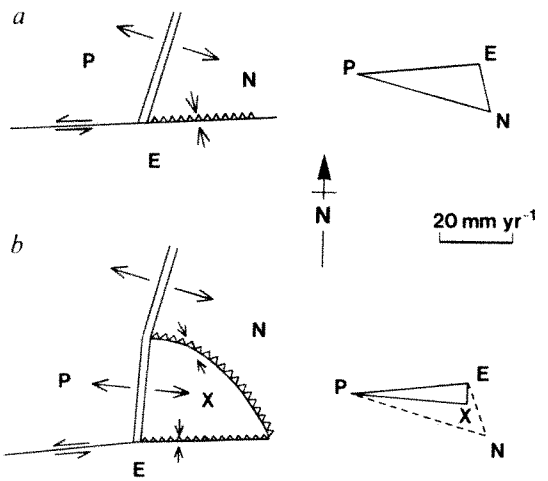

FIG. 3 *a*, Predicted[10] RFT (ridge–fault–trench) plate boundaries (left) and velocity triangle (right) for the northern microplate–EPR (Easter–Pacific–Nazca, E–P–N) triple junction. P–E and P–N diverge by 22°. *b*, Left: observed configuration at the northern triple junction. Right: velocity triangle assuming there is another plate X or deformation of the Nazca plate north of the microplate; we assumed P–X motion to be the observed[10] EPR spreading rate of 132 mm yr^{-1} at 22.6° S in a direction of 094°, normal to its observed trend and that of the structures produced by it over the past 0.75 Myr. This predicts almost north–south convergence across E–X at the triple junction. P–E and P–X cannot be colinear transforms unless the EPR is spreading 10° obliquely, and we suggest that the east–west structure observed east of the triple junction is the fossil trace of the 23° S transform. X lies close to E–N: if the corner of the Nazca plate were gradually being incorporated into the microplate by deformation, points on X should track along line N–E in velocity space; the present position of X indicates that this process is over halfway complete near the triple junction.

Microplate history

A record of the microplate's history is preserved in the tectonic fabric of its interior and in the adjacent parts of the Pacific and Nazca plates.

East of the microplate, we followed the initial outer pseudofault towards Easter Island. GLORIA, SeaBeam[12] and SeaMARC II show that its northern end is near 22.9° S, 111.3° W, ~50 km east of the north end of the East Rift. Northward propagation seems to have stalled near that position, with the rift tip recently jumping westwards[12]. We were able to trace the pseudofault south to 26.3° S, 110.0° W, where it clearly marks a 15° change in trend and distinct apparent age contrast in the spreading fabric. It probably continues closer to Easter Island, and may even cross it to reappear just to the south-east of that feature, although our evidence there is less clear. Nevertheless, it seems that the suggestion[4,18] that the formation of Easter Island is closely related in time and space to the initiation of the East Rift may be essentially correct.

As expected, the inner and outer initial pseudofaults of the East Rift are mirror images, and details of their shape, such as the more northerly strike near 24.3° S (marking a brief acceleration in propagating or deceleration in spreading rate), are matched from one to the other. Our preliminary reconstruction suggests that the East Rift began to open ~5 Myr ago, some 2 Myr earlier than previously[4,18] thought.

We have limited new data between the present East Rift axis and the outer pseudofault, but this and archived magnetics suggest a history of fairly uniform spreading, with no major discontinuities of spreading-axis direction and little or no fanning. The Pacific plate, however, shows rather confused fabric. There are several sets of curving trends indicating minor spreading-axis offsets and, near 25° S, 117–118° W, some apparent age discontinuities that suggest a continued history of rapid evolution of the West Rift for the past several million years.

We searched for a spreading fabric discontinuity west of the microplate that would mark its initiation, but found no clear-cut evidence of one. We therefore think it likely that the West Rift evolved continuously as the microplate formed.

We also investigated the major topographic ridge[7,11] that runs from 26.2° S, 117° W to 27.0° S, 114° W. Between 116° W and 118° W, E–W lineaments strike west away from this ridge, and we interpret these as the fossil traces of a multi-transform[19] fracture zone that was probably the original southern transform boundary of the microplate[4–6].

We suggest the microplate may have been initiated as follows. There seems to be a critical spreading rate on the EPR near the Easter microplate, above which transforms do not occur[20]. This may be because they are unstable at speeds for which the lithospheric strength falls below the transform's shear resist-

ance[21]. We speculate that ~5 Myr ago the sinistral-offset transform near the present southern boundary of the microplate was near its stability limit. Some event then pushed it over the limit: a small increase in spreading rate (perhaps accompanying increased discharge at the Easter mantle plume and incidentally producing Easter Island) would have critically weakened the lithosphere; alternatively, a small clockwise change of Pacific–Nazca motion, such as occurred at 3.4–3.9 Myr (ref. 22), would have made the transform transpressional and increased its resistance to slip. The resulting stresses would have made the East Rift begin to propagate and form a rotating microplate[23], causing the southern transform to open up and the West Rift to propagate along it[5].

Schouten and others[24] have presented a description of microplate kinematics in which they liken the motion of a microplate to that of a ball bearing turning between major plates. Their analysis, which predicts that both east and west initial outer pseudofaults should strike E–W, refers only to the instantaneous case; in reality, the propagating rifts leave oblique pseudofaults, and the microplate grows by accretion at the East and West Rifts. As it turns, therefore, the microplate acts more like a cam than a ball bearing, applying N–S pressure to the major plates. The Easter microplate is thus deforming the Nazca plate to its north.

The rotation emphasized in Schouten's model must be accompanied by strong vorticity in the asthenosphere. Indeed, in this region where the hot, fast-spreading lithosphere is thin and weak[4,7], the fluid motion of the asthenosphere may be dominant, and the observed brittle-plate kinematics of the sea floor may be largely a passive response to it. The strong clockwise vorticity associated with the initial transform would have continued after that transform became unstable, and been directly converted into rotation of the microplate.

Viewed at a regional scale, the microplate has produced a pattern of lineaments remarkably similar to a whorl in a fluid vortex (Fig. 2). We may here be coming close to a limit where rigid-plate tectonics and continuum-fluid mechanics are equally valid and useful descriptions of lithospheric behaviour. □

ACKNOWLEDGEMENTS. We dedicate this paper to the memory of the late Master of RRS *Charles Darwin*, Captain Sam Mayl. We also thank the rest of the company and technicians of the *Charles Darwin* for their help, D. Naar, J. Francheteau and V. Marchig for the SeaMARC and SeaBeam data and D. Naar, H. Schouten and R. Hagen for giving us preprints of their papers before publication.

Three-dimensional crystal structures of *Escherichia coli met* repressor with and without corepressor

John B. Rafferty, William S. Somers, Isabelle Saint-Girons* & Simon E. V. Phillips

The three-dimensional crystal structure of *met* repressor, in the presence or absence of bound corepressor (*S*-adenosylmethionine), shows a dimer of intertwined monomers, which do not have the helix-turn-helix motif characteristic of other bacterial repressor and activator structures. We propose that the interaction of *met* repressor with DNA occurs through either a pair of symmetry-related α-helices or a pair of β-strands, and suggest a model for binding of several dimers to *met* operator regions.

THE gene regulatory control system for the biosynthesis of methionine in *E. coli* was one of the first to be discovered[1]. Methionine, a key amino acid in protein synthesis, is the precursor to *S*-adenosylmethionine (SAM), which functions as the main intracellular methyl donor. SAM is the corepressor bound by the methionine repressor protein, one component of the regulatory system. The *Met* repressor is the product of the *metJ* gene, and represses its own gene and those coding for enzymes involved in methionine and SAM synthesis[2].

The determinations of the three-dimensional structures of proteins involved in transcriptional regulation in *E. coli* and its phages show that they have a common structural motif, formed by a pair of α-helices linked by a tight turn, in otherwise distinctly different structures. This has been called the 'helix-turn-helix' motif, and has been implicated in the sequence-specific DNA-protein binding of the phage λcI repressor protein and the cro protein[3,4], the related phage 434 repressor and Cro proteins[5,6], the *E. coli* cyclic AMP-binding protein (CAP)[7] and the *E. coli trp* repressor[8]. In these dimeric proteins the second helices, or 'recognition helices', of symmetrically related motifs have been postulated to insert into adjacent turns of the major groove of approximately B-form DNA. This has been confirmed directly

by the crystal structures of the DNA complexes of the *trp* repressor[9], the phage 434 repressor and the Cro protein[10,11] and λ cI repressor[12].

We report here the crystallographic structures of the *met* repressor in the presence and absence of bound SAM, determined at 1.9- and 1.7-Å resolution, respectively. The *met* repressor is a dimer comprised of two highly intertwined monomers, which do not contain helix-turn-helix motifs. On the basis of model-building experiments we suggest ways in which the protein might recognize its DNA target through two symmetry-related α-helices or a pair of β-strands.

The *metJ* gene has been cloned, its nucleotide sequence determined[13], and the repressor protein overexpressed and purified[14]. It is a polypeptide of 104 amino acids of relative molecular mass (M_r) 11,996 and exists as a stable dimer in solution. Two molecules of SAM bind non-cooperatively to each metJ dimer, thereby increasing its affinity for DNA markedly[15].

The *met* biosynthetic genes under the control of the *met* repressor are scattered throughout the chromosome over at least six loci[2]. An examination of the operator sequences reveals an underlying 8-base pair (bp) repeating unit, referred to as a 'met box', in two to five tandem copies.

In an attempt to explain the variation of operator length and the results of biochemical and genetic experiments[15], we propose a model that involves the binding of several repressor dimers to tandem sites in the operator regions.

Structure determination

Crystals of the aporepressor were grown from PEG600 (polyethylene glycol of average M_r 600) by the hanging-drop vapour-diffusion method[16]. Native X-ray diffraction data were collected to a resolution of 1.7 Å on an area detector system (Xentronics) and phased using isomorphous and anomalous 3 Å derivative data collected on a diffractometer (Enraf-Nonius CAD4) (Table 1). Initial electron-density map fitting was carried out at 3 Å resolution by using the program FRODO on a computer graphics system (Evans and Sutherland PS300). Density corresponding to the polypeptide backbone was strong and clear, but was improved by averaging about the dimer 2-fold axis, and solvent flattening[17,18]. After the initial model-building stage the 2-fold averaging was discontinued and the structure subjected to restrained least-squares refinement[19], resulting in the current *R*-factor of 0.21 for all data in the range 10–1.7-Å resolution.

Crystals of SAM-bound repressor were grown using microdialysis, by dialysing out Mg^{2+} ions. Data were collected to 1.9 Å resolution on an area detector system (Xentronics) and the structure was determined by molecular replacement. Aporepressor coordinates were used as a starting point for rotation- and translation-function searches, with unambiguous solutions found for both functions. Electron-density maps were generated based on calculated phases, and model building and refinement carried out as for the aporepressor. Two SAM molecules were located as positive difference density peaks in the maps. To avoid bias towards the starting model, segments of the structure in regions of poorly defined density were removed and the maps were recalculated. The *R*-factor now stands at 0.22 for data in the range 10–1.9 Å resolution.

Repressor structure

For both forms of the repressor, the electron density map is clear from the N-terminus to the C-terminus. The map reveals two highly intertwined monomers creating the dimer. Each

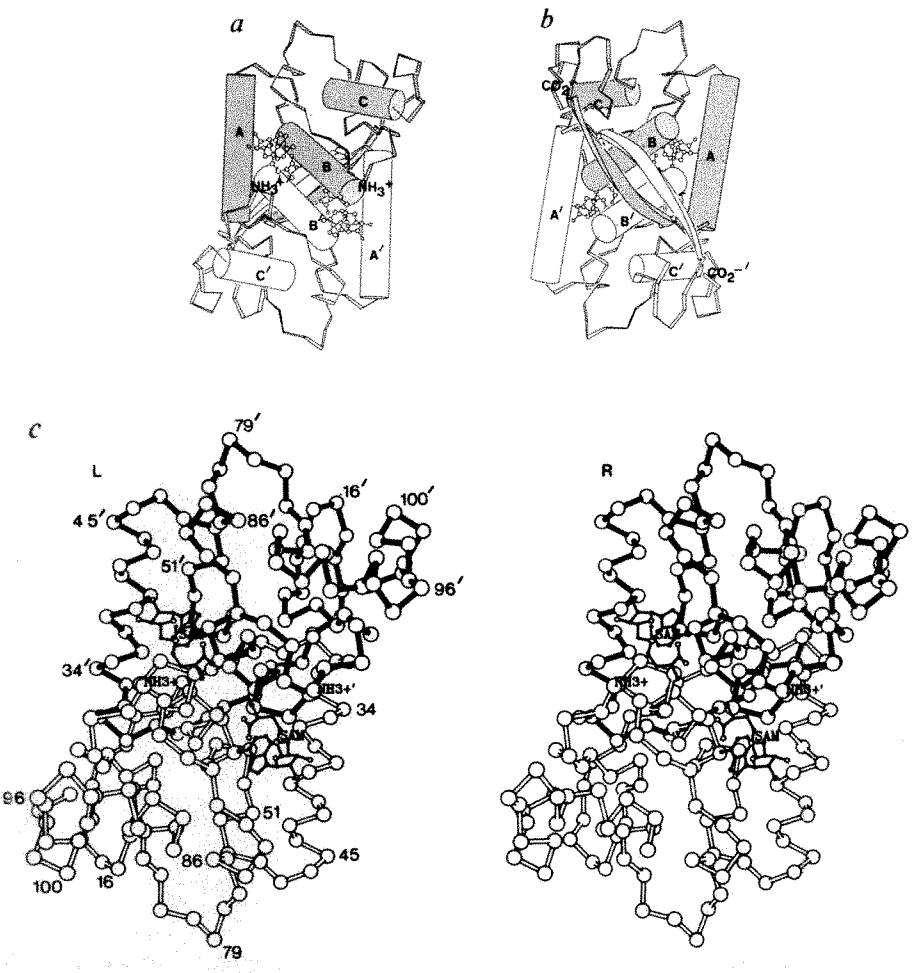

FIG. 1 SAM-bound *met* repressor. *a*, *b*, Dimer with helices represented as cylinders, β-strands as thick arrows and rest of chain as ribbon. One monomer is displayed shaded. *a*, View along dimer dyad axis into face containing C-helices. *b*, View along dyad axis in opposite direction to *a*, showing intertwined β-strands. Helices are labelled A, B, and C (A′, B′ and C′) and the termini NH_3^+ and CO_2^- ($NH_3^{+\prime}$ and $CO_2^{-\prime}$). *c*, View is a stereo α-carbon backbone trace of the dimer as 'ball and spoke' in the same direction as *a*; one monomer has open bonds and the other shaded bonds. Selected residues are numbered in one view, the presence or absence of a prime symbol differentiating the monomers. SAM is shown in all-atom form. Aporepressor structure is not shown, but apart from the SAM and the flexible loops, which are remote from the proposed DNA-binding region, it would be indistinguishable. The first flexible loop (His 14–Glu 19) is immediately before the β-strand and the second (Lys 78–Ser 81) between helices B and C close to the first loop in space.

†† Mean figure of merit for relative phase accuracy over all reflections.

monomer is composed of three α-helices (A-helix, residues 30–45; B-helix, residues 52–66; C-helix, residues 86–94) and a β-strand (residues 20–29), which account for 50% of the polypeptide; the remainder consists of turns or extended chain (Fig. 1). The *met* repressor does not possess a helix-turn-helix motif.

The dimer contacts are made along adjacent faces of the 2-fold related B-helices and by the β-strands. The antiparallel β-strands loop over one another and firmly establish the intertwined dimer. Substantial inter-monomer contacts have also been observed for *trp* repressor[8], where the predominantly α-helical monomers intertwine. Symmetry-related interactions occur between the N-terminal end of the B-helix and the β-strand of the other monomer, and between the C-terminal ends of the B-helices.

Examination of the dimer interface explains a spontaneous point mutation[20] that leads to non-functional repressor—a change of the Ala 60 codon to a Thr codon. This change results in a reduction of the levels of the dimer obtained[2] and suggests an increased accessibility to proteolytic cleavage. We propose that the mutation hinders dimerization, because residue 60 lies in the interface between the B-helices.

The inner B-helix is flanked by the A-helix, which links it to the β-strand. Side-chain interactions between A-helices and B helices fix their relative orientations. A stretch of open chain, including an eight-residue loop, joins the B-helix to the C-helix. A network of hydrogen-bonded side chains links this loop and the side chains and backbone of the C-helix, thereby determining its position.

Throughout both structures 2-fold symmetry is well maintained. The only main departures arise at the turns (His 14–Glu 19) leading to the β-strands, and can be accounted for by differences in the crystal lattice environment. An examination of the two structures shows that all four equivalent regions are the most variable parts of the protein and, by implication, very flexible. The other notable departure from 2-fold symmetry occurs in the aporepressor structure at a loop (Lys 78–Ser 81); here the side chain of Lys 78 bridges the loop in one monomer, but the side chain of Arg 80 bridges it in the other monomer. The latter arrangement is also seen in the loops in the SAM-bound structure.

Corepressor binding

S-adenosylmethionine binds to the *met* repressor dimer at two independent, symmetrically related sites, as seen in the crystal structure. This confirms the results of equilibrium dialysis experiments[2], which indicated that SAM binds to the dimer with a stoichiometry of 2:1. The binding sites are located close to the 2-fold dimer axis and on the same face of the protein as the

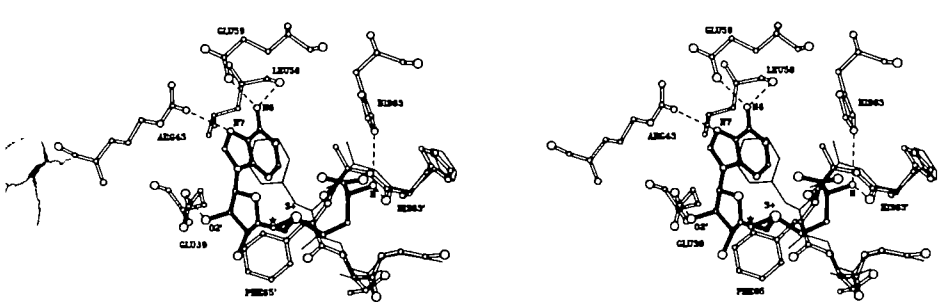

FIG 2 Stereo view of a SAM molecule-binding site. Protein is in open ball-and-spoke representation for SAM-bound form (=) and as simple shaded stick representation for apo- form (–), showing movement of the side chain of Phe 65'. A SAM molecule is shown in shaded ball-and-spoke representation and hydrogen bonds denoted by dashed lines. The two monomers are differentiated by presence or absence of a prime symbol after residue numbers and the activated methyl group of SAM marked with an asterisk.

C-helices. The binding of SAM involves the insertion of its purine ring into a hydrophobic pocket on the protein surface. Comparison with the aporepressor structure shows that this pocket is otherwise occupied by the phenyl ring of Phe 65′, which is swung out of the way when SAM is bound (Fig 2) The activated methyl group of SAM results in a trivalent sulphur atom which carries a positive charge. Closer examination of the location of the binding site shows that it is at the C-terminal end of the B-helix, with the sulphur <3.4 Å from the carbonyl oxygen of Ala 64. The helices are dipolar and the positive sulphur is thus positioned near the net negative C-terminal end.

The hydrophobic pocket, into which the purine ring is inserted, is formed by the side chains of Leu 70, Ala 64′, Phe 61′, Leu 56, the peptide plane that joins Ala 64′ and Phe 65′, and interactions from the side chains of Glu 59 and Arg 43. There is no 'adenine recognition loop' as proposed by Remington *et al.*[21] for citrate synthase. Each SAM molecule makes symmetric hydrogen-bonded contacts with both monomers (Fig. 2). The contacts are formed between the adenosyl and methionine moieties of SAM, and the backbone and side chains of the A- and B-helices. Hydrogen bonds from the carbonyl oxygen of Leu 56 and side-chain carboxyl oxygen of Glu 59 to N6, in addition to one from the guanidino group of Arg 43 to N7, help to position the purine ring. A further contact is made between O2 of the C3′endo-ribose ring and the carboxyl group of the side chain of Glu 39. Finally, the amino nitrogen, N, of the methionyl moiety contacts the ring $N_\varepsilon 2$ of His 63 and the carbonyl oxygen of the related residue His 63′ in the other monomer.

There does not seem to be any major change in the dimer conformation on the binding of SAM. A comparison of the structures for both forms of the repressor, by least-squares fitting of their equivalent α-carbons using the program PUBFIT, shows an excellent superimposition, apart from the flexible loops mentioned above. The r.m.s. deviation for the fitting of the α-carbons of aporepressor to SAM-bound repressor, excluding the flexible loops, was 0.43 Å, compared with 0.34 Å and 0.34 Å for the fitting of the non-crystallographically related monomers to each other in the aporepressor and SAM-bound repressor dimers, respectively.

DNA binding model

The binding of the *met* repressor occurs at several operator regions of different lengths on the *E. coli* chromosome[2]. But underlying this variation is the repeating 8-bp met box unit. Its consensus sequence, dAGACGTCT, has been determined by sequence analysis of the operator regions and is an inverted repeat. There are integral numbers of met boxes (between two and five) upstream of the genes that are controlled by *met* repressor. A comparison of the natural operators to the consensus reveals a trend of a decrease in homology as the number of met boxes increases[15]. In operators that contain more than two met boxes the homology to the consensus is usually higher in the central boxes. Genetic studies, such as operator constitutive mutations in the operators of *E. coli metF, metC* (ref. 15) and the *Salmonella typhimurium metB*[22], as well as filter-binding experiments in which synthetic sequences are used, have confirmed that repeating met box sequences constitute specific targets for the binding of repressor

Structural studies of other repressor systems have indicated that dimers of similar size to *met* repressor contact between 14 and 18 bp of essentially B-form DNA. Recent structures of protein–DNA complexes[9,10,12,23,24] show that DNA distorts on the binding of protein, but it is not possible to predict what distortions, if any, might occur in the met boxes. NMR data from a 16-bp segment that is closely homologous to two met boxes is consistent with that of B-form DNA in solution (J. Parkinson, personal communication). We therefore modelled a 32-bp segment of ideal B-form DNA, composed of four met boxes (for example, the length of the *metA* operator) with a 10.5 bp helical repeat, on a computer graphics system. An initial assumption was made that the 2-fold axis of the dimer would coincide with that between two met boxes, such that each half of the dimer experienced an identical environment when bound to the operator. Note that symmetry can be maintained if the dimer axis is considered coincident with the central 2-fold axis of a met box, and the binding interaction is thus offset by 4 bp relative to the first alignment. In either alignment there remain only two degrees of freedom in modelling the overall geometry of the repressor–operator interaction, excluding the possibility of changes in the structure of the DNA and/or the protein on binding. These degrees of freedom are the relative separation of the protein and the DNA, and their relative rotation about their common 2-fold axis. The orientation of protein and DNA were initially chosen so that the face of the protein that contains the C-helices approached two adjacent turns of the major groove and one central turn of the minor groove. Because of the prominent nature and relative separation (35 Å) of the C-helices, we propose that they form part of the binding site for DNA in an analogous way to that observed for the helix-turn-helix motif.

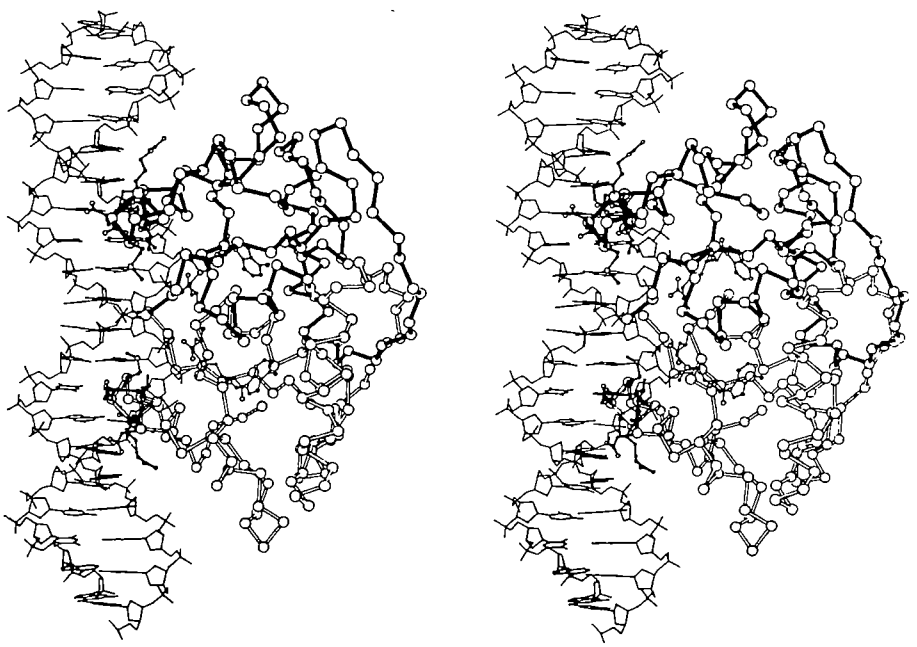

FIG 3 A stereo pair showing a single dimer binding with inserted C-helices to a piece of B-form DNA comprised of repeating met boxes as generated on a computer graphics system The dyad axis of the dimer is coincident with the 2-fold axis between met boxes DNA is shown in stick form, the protein monomers as an α-carbon trace in open and shaded ball-and-spoke form and the SAM and residues Glu 90, Ile 91, Arg 93, Glu 94 and Met 95 as all atom. In the model shown, the fit of the C-helices in the major groove has been maximized; this has, however, resulted in the first three N-terminal residues approaching the DNA phosphate backbone too closely The alternative model with the β-strands inserted into the major groove can be imagined by translation of the repressor dimer 'through' the DNA (that is, to the left) along the mutual dyad axis, followed by a small clockwise rotation about this axis.

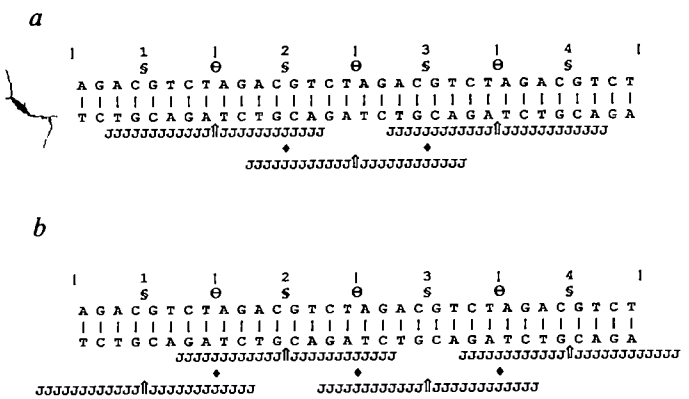

FIG. 4 Schematic representations of the model for multiple repressor binding to met boxes. Shown are four perfect consensus met boxes (1–4), to which are bound MetJ dimers (JJJJ) at sites centred 8-bp apart *a*, Dimer dyad axes coincident with axes between met boxes. *b*, Dimer dyad axes coincident with 2-fold axes within met boxes. Axes between the met boxes are shown by Θ and within the met boxes by §. Dimer dyad axes are shown by arrows and the 2-fold axes between dimers by solid diamonds.

Docking of the protein and DNA was done manually using interactive computer graphics; the C-helices were readily inserted into the major groove to form a very good fit (Fig. 3).

This simply fitted model showed a good overall surface complementarity, and the possibility of specific contacts between the base-pair edges and protein side chains in the manner proposed by Seeman *et al.*[25]. The C-helices lie approximately parallel to the major groove but with their carboxy termini penetrating more deeply into it. Several hydrogen bonds could be formed between the side chains of residues Glu 86, Lys 89, Glu 90, Arg 93 and Glu 94 of the C-helix, and the bases and phosphate backbone of the DNA. There could also be a favourable van der Waals' contact formed between the side chain of Ile 91 and the base-pair edges. Further similar hydrogen bonding and van der Waals' contacts could also be made by the first two residues at the N-terminus, Ala 1 and Glu 2, and by the side chains of residues Asp 72, Arg 80, Met 95 and Asn 98 to form a substantial interface.

An alternative arrangement can also be modelled in which the antiparallel β-strands on the opposite face of the dimer are inserted into the major groove. This model does not show as good a complementary fit to the DNA; the buried surface area of protein and DNA in the complex is 208 Å^2 compared with 585 Å^2 for the model with inserted C-helices, expressed as solvent accessibility[26] using a probe of radius 1.4 Å. But this alternative model cannot be discounted as it has identical symmetry to the previous model and is sterically feasible. Experiments using site-directed mutagenesis are at the moment being performed to determine which of these binding models represents the DNA–protein interaction in solution.

The binding of corepressor causes little conformational change in the repressor structure as mentioned above. This is in contrast to the situation with the tryptophan repressor, where binding of the co-repressor causes the helix-turn-helix motifs to move markedly further apart[27] and increases affinity of the repressor for DNA. A similar allosteric mechanism has been proposed for the activation of CAP by the binding of cAMP (ref. 7), but it would not seem to be the case for the methionine system. The possibility exists, however, that the act of crystallization of the protein could have locked the aporepressor and repressor–SAM complex into the different lattices with fortuitously similar conformations, although there is no evidence to substantiate this hypothesis.

Our model with inserted C-helices places SAM in the protein–DNA interface. SAM fills a gap between the surfaces of the protein and the DNA, and a possible contact could be made between the methionyl moiety of SAM and the phosphate backbone. The corepressor is positioned between the net negative C-terminus of the B-helix and the negatively charged phosphate backbone of the DNA, and its positively charged sulphur

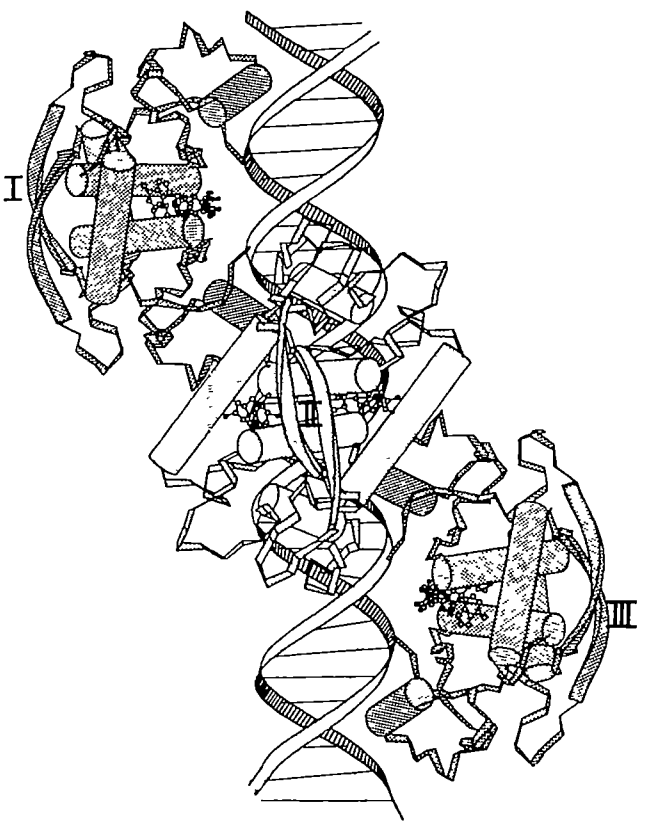

FIG. 5 Diagram of the multiple repressor binding model for three MetJ dimers bound with inserted C-helices to a 32-bp segment of B-form DNA represented as a helical ladder. The sides are formed by the deoxyribose phosphate backbone and the rungs by the base pairs. Dimers are labelled I, II and III forming a left-handed helix, with an 8-bp rise per dimer and a relative rotation about the DNA of ~85°.

functions perhaps as a counter-ion. This feature could offer an explanation of how SAM functions to increase DNA affinity and why the close structural homologue *S*-adenosylhomocysteine, which lacks the activated methyl and hence the positive charge on the sulphur, is inactive as a co-repressor (I. Parsons *et al.* manuscript in preparation). How SAM could function in the model with inserted β-strands is not immediately obvious.

In the light of recent structural determinations of repressor–operator complexes, we hesitate to propose a more detailed interpretation of the interactions. We have obtained a crystal form of a *met* repressor–operator complex suitable for X-ray-structure determination, which in conjunction with site-directed mutagenesis experiments, should provide the details of the protein–DNA interaction.

Model of binding involving several dimers

An intriguing feature of the *met* regulatory system is the action of the repressor on operators with various numbers of tandemly repeated met boxes. DNase protection experiments involving the *metF* operator[15] show coordinate protection of all five met boxes that is a total of 40 bp, by the *met* repressor. We believe that several repressors must bind to such operators[15]. It could be that a repressor dimer merely contacts one 8-bp met box, as observed for our model with inserted β-strands, but our favoured model with inserted C-helices indicates a binding site of nearer 16 bp. This poses the problem of why a dimer seems to protect odd numbers of 8-bp met boxes. Detailed biochemical and genetic experiments with both natural and synthetic operator sites indicate that repressor binds cooperatively to sites of tandem repeats of 8 bp units[15].

We propose here a structural model that involves the binding of repressor dimers to overlapping sites in the *met* operators. A similar proposal has been made for the *trp* repressor system[28], although the idea has been opposed on the basis of results from stoichiometry measurements[29]. Our postulated arrangement can accommodate binding to various numbers of met boxes, including the number present in the *metF* operator. Because of the 2-fold symmetry at the centre of met boxes as well as between them, however, exact positioning of the *metJ*-encoded dimer can be achieved in either of two alignments outlined above, while maximizing the use of available symmetry (Fig. 4). In alignment one (Fig. 4*a*) the dimer axis coincides with the 2-fold axis between met boxes, and in alignment two (Fig. 4*b*), it coincides with the central axis of a box, resulting in n met boxes binding $n-1$ or n dimers, respectively.

In more detail, a repressor is proposed to bind and enhance subsequent repressor binding at sites centred 8 bp apart along the DNA. Increased affinity for additional repressor binding may result from protein–protein contacts between the turns (Glu 94–Gly 96) following the C-helices of adjacent dimers in the major groove of the DNA (Fig. 5). Possible non-covalent contacts could occur between the side chain of Met 95, the main-chain atoms of the turn and the N-terminal residues, and those from the related residues in an adjacent dimer. These contacts may account for the cooperativity of operator binding[15].

This model can also explain the additional 2-fold symmetry in a met box which would coincide with the 2-fold axis between adjacent protein dimers in alignment 1 (Fig. 4*a*) or the dimer 2-fold axis in alignment 2 (Fig. 4*b*).

When viewed in terms of a 3-D model (Fig. 5), the dimers form a left-handed superhelix around the DNA with an 8 bp rise per dimer and a rotation of ~85°. The model permits this overlapping of sites and juxtaposition in the major groove of the C-helices from adjacent dimers without steric clashes, while a reasonable fit of these helices in the major groove is maintained. A similar model could be made for binding through the β-strands, which would allow possible cooperative interactions without steric clashes between dimers centred 8 bp apart.

Although this is only a model, it provides explanations for various observations in binding experiments and uses all the available symmetry in the system. Experiments are underway to test the validity of the idea. □

Note added in proof: We have recently solved the crystal structure of a repressor–operator complex, which shows two Met-repressor dimers bound to a synthetic 19-mer oligonucleotide containing two met boxes. The dimers bind in alignment 2, with their β-strands inserted into the major groove. They form a left-handed superhelix around the DNA, with protein–protein interactions between them, as predicted in this paper.

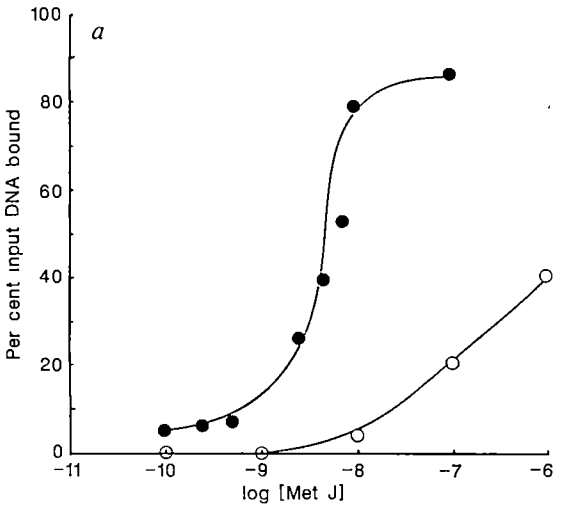
We present biochemical and genetic data to support the hypothesis that the *Escherichia coli met* repressor, MetJ, binds to synthetic and natural operator sequences in tandem arrays such that repression depends not only on the affinity of the DNA–protein interaction, but also on protein–protein contacts along the tandem array. This represents a novel form of regulatory switch. Furthermore, there seems to be homology between the organization of the *met* and *trp* operators.

MANY gene regulatory events are mediated by the interaction of several proteins, which simultaneously make contacts with each other and specific DNA sequences[1]. Bacteriophage λcI repressor, for example, binds cooperatively to operator sites O_R1 and O_R2, each dimer of repressor contacting adjacent DNA sequences and a neighbouring repressor. Activation of eukaryotic transcription seems to require the interaction of a series of DNA-binding proteins, many of which are in contact with each other as well as with DNA, and act together to facilitate the binding of RNA polymerase[2] In this issue Rafferty *et al*[3] report the determination, by X-ray crystallography to high resolution, of the crystal structure of the *E. coli* methionine aporepressor, MetJ, and its complex with the corepressor, S-adenosylmethionine (SAM). A model for the binding of repressor to DNA is also proposed, and it is suggested that tandem binding accounts for features of the natural *met* operators. Here we present genetic and biochemical evidence that supports this hypothesis and implies that transcription of genes in the methionine biosynthesis pathway is controlled not only by protein–DNA interactions, but also by protein–protein contacts formed between adjacent repressor dimers along the DNA duplex. This model for the interaction of MetJ and DNA explains the biochemical data and is consistent with the results of the structural studies

Methionine biosynthetic pathway

The biosynthesis of methionine is accomplished by a series of transformations from other key metabolites[4] Several stages of the pathway are common to the biosynthesis of other major metabolites, such as diaminopimelate, lysine, threonine and isoleucine, and the pathway culminates in the activated methyl cycle, a key metabolic control point. Flux through this pathway is mainly controlled by the product of the *metJ* gene, the MetJ repressor, which acts at at least six operators dispersed throughout the genome. The activity of MetJ is regulated not by methionine, but by another product of the pathway, SAM[5,6]. The cell must therefore control the levels of transcription of selected genes in a pathway used not solely for methionine biosynthesis, by sensing the level of a central metabolite, SAM A clue to the possibility that the repressor does not act by a simple series of on/off switches is provided by an analysis of the 5′ flanking regions of the regulated genes. This reveals an eight-base pair (bp) tandem repeat or 'met box', with a consensus repeat sequence of dAGACGTCT (ref. 7; Table 1). The number of met boxes varies considerably from two in *metC*, to five in *metF* and *metB*. The shortest naturally occurring operator (*metC*) has two met boxes and could represent the minimum operator length. There are no perfect met-box consensus sequences in the natural *E. coli* operators, although a single perfect met box has been reported in the *metR* operator of *Salmonella typhimurium*[8].

Probing operator–repressor interactions



To test whether repressor can bind to a perfect consensus operator *in vitro*, we cloned a synthetic 16-mer oligonucleotide corresponding to two tandem met boxes into the *Sma*I site of the plasmid pUC18, and used the operator insert flanked by the polylinker sequence in filter-binding and gel-retardation studies of DNA–protein interaction. Figure 1*a* shows the result of a filter-binding assay in which this consensus operator was used in the presence or absence of SAM. The protein showed a very pronounced enhancement of binding to the consensus in the presence of SAM (half-maximal binding $\simeq 4.5 \times 10^{-8}$ M) and binding did not reach saturation in the absence of SAM The binding curve in the presence of SAM is distinctly sigmoid, indicating cooperative binding. Scatchard plots of the binding data (data not shown) also indicate positive cooperativity. Similar behaviour has been observed for other repressor proteins that bind DNA as dimers but which can dissociate into monomers at low concentration[1]. Monomers of *met* repressor,

The met box sequences from six *E coli met* operators[24] have been aligned and a consensus sequence deduced As explained in the text, the minimum size of the operator is expected to be that of two such met boxes, that is 16 bp The sequences of the operators are shown together with their percentage homology to the consensus (indicated under each met box) Upper-case letters denote residues homologous to those of the consensus Note that in general the homology to the consensus is best in the shorter operators, and towards the centre of the longer ones

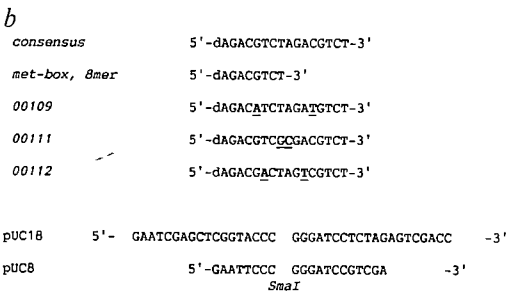

FIG 1 Filter-binding of operator constructs Synthetic oligonucleotides comprising the perfect 16-mer consensus sequence, the 8-bp half-site and sequence variants, were ligated into *Sma*I-cleaved pUC18, which was then used to transform *E. coli* TG1 to the ampicillin-resistant phenotype on 5-bromo-4-chloro-3-indolyl-β-galactopyranoside/isopropyl-β-D-thiogalactopyranoside plates Plasmid DNA from white colonies was sequenced to confirm the presence of the desired insert The polylinker containing the operator site was then excised by digestion with *Eco*RI or *Hin*dIII (or both) and radiolabelled with Klenow polymerase and [α-^{32}P]dNTPs, followed by the second digest and purification over polyacrylamide gels The 78-bp radiolabelled fragment was then used in a nitrocelluose filter-binding assay[25] (I P, P G S and J Parkinson, manuscript in preparation) Essentially, varying concentrations of MetJ were complexed with the target DNA fragment in 0 1 M KCl, 10 mM Tris-HCl, 0.5 mM EDTA, pH 8 0, at 37 °C for 60 min before filtering. The control pUC18 polylinker fragment lacking any insert produced no detectable binding even at the highest protein concentrations (~10^{-6} M) *a*, Filter-binding of the perfect consensus 16-mer sequence in the presence (●) or absence (○) of 0 1 mM SAM *b*, Sequences of the synthetic operator sites, together with the polylinker sequences into which they were cloned in either pUC8 or pUC18 Variations from consensus are underlined

however, are extensively intertwined[3], a feature seen in the *trp* repressor[9] and which presumably accounts for the large amount of free energy required to dissociate *trp* repressor dimers[10].

As well as a perfect consensus of two met boxes, we tested a construct containing a single met box. This construct had a markedly lowered affinity for repressor; it failed to saturate at protein concentrations at which binding is sequence-specific, as did a series of sequence variants (Fig 1*b*) in which residues throughout the central region of the 16-bp consensus were changed, including those at relatively conserved positions. All the sequence changes result in operators with dramatically reduced affinities for repressor (data not shown); in the presence of corepressor they bind less strongly to repressor than does the perfect consensus even in the absence of corepressor, although all the operators show SAM dependency These data indicate that the two met-box 16-bp site can act as an efficient operator, that two base-pair changes in the 16-mer oligonucleotide can have a profound effect on the affinity of the protein for DNA and also that bases at the centre of the 16-mer are important for repressor binding.

We carried out a similar series of experiments in which site-directed mutants of the natural *metC* operator were used. The *in vivo* phenotypes of the mutated *metC* operators were analysed by using a *lacZ* reporter gene. The *metC* operator contains two met boxes with three sequence differences from a perfect consensus With a single exception, stepwise modification of the sequence resulted in a small increase in repression activity with every alteration towards the consensus sequence, and a distinct drop in activity with mutations away from the consensus (Fig. 2*a*).

To determine precisely which regions of the perfect consensus–pUC18 polylinker are bound by the repressor, we carried

out both DNase I protection[11] and methylation protection–interference[12] experiments (results summarized in Fig. 3*a*). The nuclease footprint is roughly centred on the consensus 16-mer oligonucleotide, but extends to either side of it by about 8 bp. The methylation experiments also revealed protein contacts outside the consensus region. Similar results for nuclease protection were obtained with the natural *metC* operator.

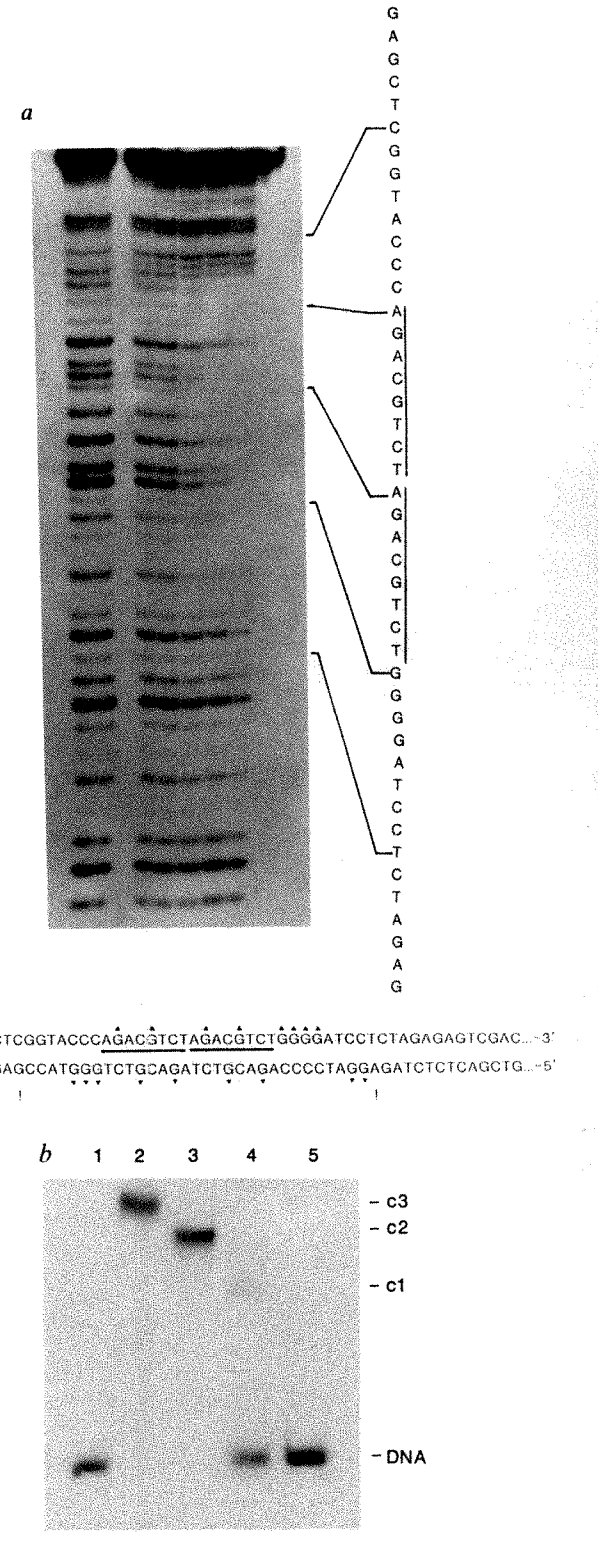
The dimensions of the repressor protein indicate that these protection patterns could not be generated by a single MetJ dimer unless the DNA is wrapped around the protein, which seems unlikely in view of the small radius of such a complex. Such a model seems even less likely when the results of nuclease protection assays on larger natural operators are considered (see below); the simplest interpretation is that several protein molecules are bound.

We tested for this binding of several protein molecules by performing gel retardation assays[13,14] (Fig. 3*b*). Test fragments were retarded in the presence of repressor protein and SAM. Even at the lowest protein concentrations at which binding occurs, up to three retarded species (c1–c3) were observed, which were converted to the most retarded band, c3, with increasing protein concentration. This is consistent with the formation of a series of protein–DNA complexes, each differing by the addition of further repressor dimers. All experiments involving DNase I and methylation protection were performed at concentrations at which the chief species present would be c3, indicating that c3 at least is a complex that contains multiply bound proteins. Similar experiments involving several perfect met-box sequences tandemly arranged and cloned into the plasmid pUC8 showed that there is an increase in the numbers of retarded complexes with increasing numbers of met boxes, such that an increase in the size of the operator site by one extra met box (8 bp) results in one extra retarded complex (data not shown). Preliminary analysis indicates that increasing the number of met boxes decreases the protein concentration at which retardation to larger complexes occurs, consistent with cooperative repressor binding (I.M. and P.G.S., manuscript in preparation).

The binding of several repressor dimers can also be demonstrated for the longer natural operators, such as *metF* which has five met boxes. Analysis of a series of mutant *metF* operators is shown in Fig. 2*b*. Point mutations and insertions (indicated by arrows) are shown, together with the operator function (in parentheses) as a percentage of wild-type function (100%), again measured from *lacZ* fusions. It can be seen that point-mutational changes throughout the five met boxes of the *metF* operator can lead to dramatic (10- to 100-fold) reductions in the activity of the repressor *in vivo*. Operators with mutations towards the perfect consensus had repression ratios that were higher than those of wild-type operators. But the most striking result from these data comes from an analysis of point insertions in the operator sequence. In particular, point insertions at positions between +13/14 and +17/18 lowered the measured repression rates by 100-fold or 50-fold, respectively. The start of transcription lies 5′ to these met boxes, and effective repression might be expected should only met boxes 1 and 2, or 4 and 5 be bound. A simple interpretation of these data is that binding of MetJ repressor dimers to this operator is cooperative, and depends on protein–protein contacts being made which are disrupted by base insertions, whereas DNA sequence changes merely alter the intrinsic affinity of the DNA–protein interaction between the operator and a single repressor dimer. This hypothesis is consistent with DNase I footprinting of the *metF* operator revealing coordinate protection across the entire 40 bp[15].

Cooperative tandem-binding model

To account for these data in a consistent manner we propose a model for the interaction, which predicts the protection of several 8-bp sites by the binding of repressor dimers to tandem



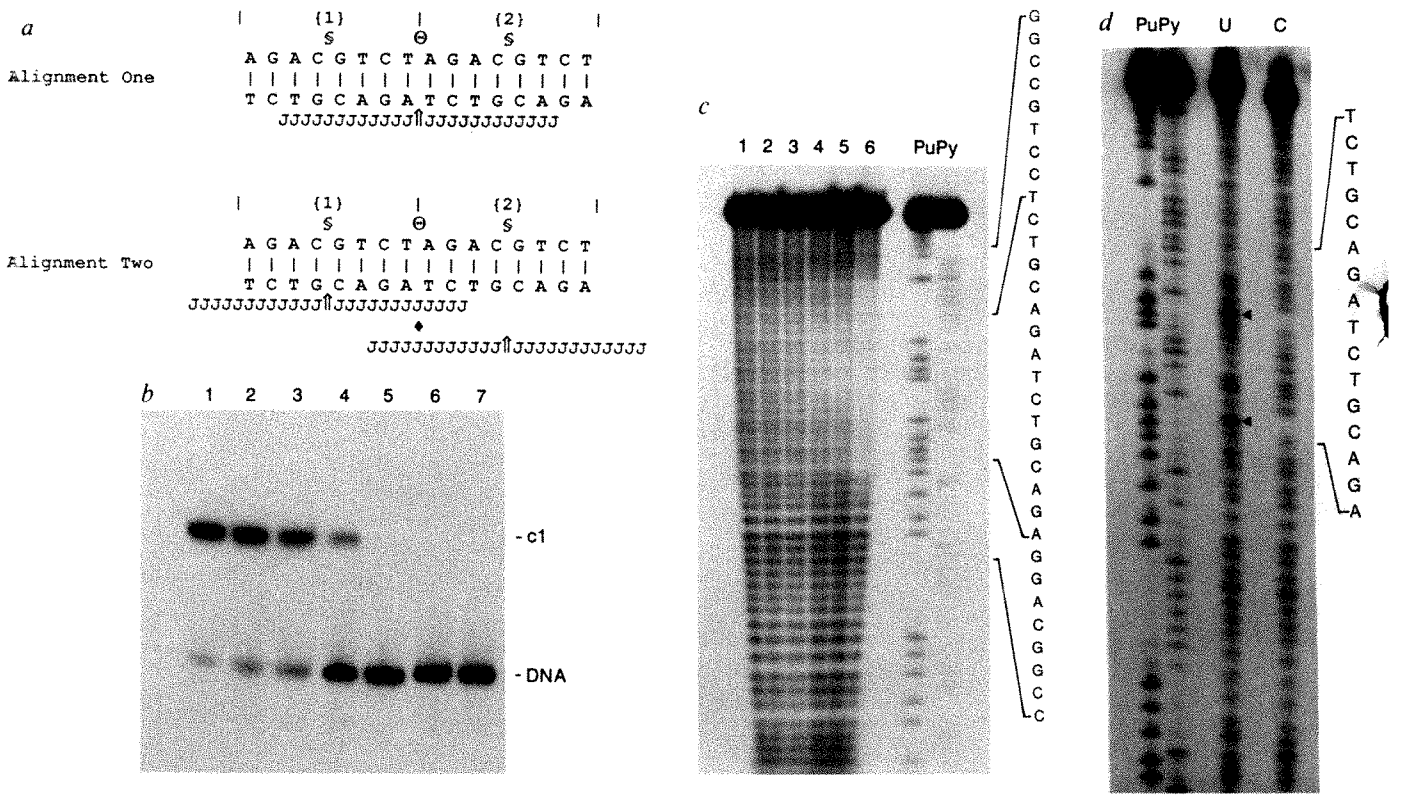


FIG. 3 Tandem binding of repressor proteins. *a*, Autoradiograph (top) of DNase I digestions of the pUC18–16mer construct (bottom strand) in the presence of increasing amounts of repressor. Lane 1, no MetJ; lane 2, 3.0×10^{-9} M MetJ; lane 3, 6.0×10^{-9} M MetJ; lane 4, 12.0×10^{-9} M MetJ; lane 5, 25.0×10^{-9} M MetJ; lane 6, 50.0×10^{-9} M MetJ; lane 7, 100×10^{-9} M MetJ. Below is a summary of DNase I and DMS protection of the complex formed between MetJ and the perfect pUC18–16mer construct (underlined). The limits of nuclease protection on the bottom strand are indicated by an exclamation mark, and bases protected from methylation by ▲. *b*, Gel retardation of pUC18–16mer consensus construct. Gels were run at pH 7.0 in 10 mM phosphate buffer and contained 0.1 mM SAM (I.M. and P.G.S., manuscript in preparation). Lane 1, no MetJ; lane 2, 0.5×10^{-6} M MetJ; lane 3, 0.5×10^{-8} M MetJ; lane 4, 0.5×10^{-10} M MetJ; lane 5, 0.5×10^{-12} M MetJ.

sites. This would allow repressors to be in such close contact that the cooperativity can be understood in terms of protein–protein interaction. Although such a tandem-binding model is structurally feasible, two ambiguities remain in the exact placement of repressor dimers on met-box sequences. The DNA site contains two distinct classes of 2-fold axes of symmetry—at the centre of a met box and at the junction between them—either of which could be coincident with the repressor dyad, and in either case the C-helices or the β-strands of the repressor could interact with the DNA[3]. Figure 4*a* shows the two possible alignments for the placement of repressors along the DNA, which indicate different stoichiometries for repressor–met-box interactions; that is, for alignment 1 we predict a stoichiometry of $n-1$ repressor dimers bound per n met boxes, whereas for alignment 2 we predict n repressor dimers per n met boxes. The analysis becomes more difficult if overlaps into flanking sequences occur, as they clearly do in the experiments with the synthetic consensus and in the *metC*-operator. We have designed an 'anti-met-box' 8-bp sequence in which we incorporated at each position in the equivalent met box the least frequently occurring

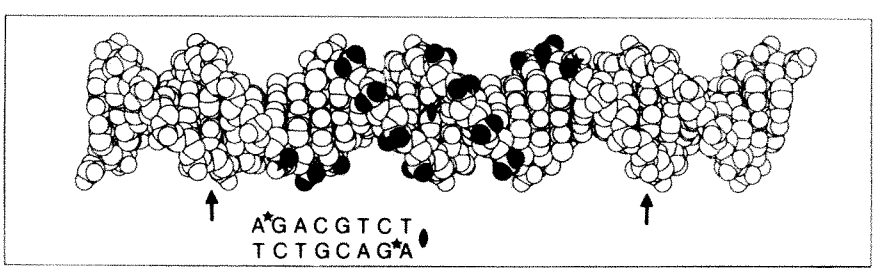

FIG. 4 Determination of the 'true' repressor-binding site. *a*, Schematic representation of the two possible arrangements for placing repressor dimers on multiple met-box operator sites. DNA twofold axes between met boxes are shown by Θ and within met boxes by §. Repressor dimers are shown as 'JJJJ', with dimer dyad axes as arrows, and twofold axes between dimers as solid diamonds. *b*, Result of gel retardation using the pUC8–anti-met-box construct. Only a single retarded complex (c1) was seen at the protein concentrations used to generate the MPE footprint (Fig. 4*c*). Similar results were obtained in the presence of a control DNA fragment which was not retarded. Concentrations of MetJ monomer: lane 1, 1.1×10^{-6} M; lane 2, 8.1×10^{-7} M; lane 3, 5.4×10^{-7} M; lane 4, 2.7×10^{-7} M; lane 5, 1.1×10^{-7} M; lane 6, 5.0×10^{-8} M; lane 7, no protein. *c* Result of footprinting a complex between the pUC8–anti-met-box construct and MetJ repressor using MPE. Concentrations of MetJ monomer: lane 1, no protein; lane 2, 6.0×10^{-9} M; lane 3, 47.0×10^{-9} M; lane 4, 190.0×10^{-9} M; lane 5, 375.0×10^{-9} M; lane 6, 500.0×10^{-9} M (top strand is shown). Footprinted DNA was analysed on 12 or 20% (w/v) polyacrylamide sequencing gels, and the resulting autoradiographs densitometered to determine the extent of protection quantitatively. Pu, purine; Py, pyrimidine. *d*, Result of phosphate ethylation interference experiment. Ethylated DNA was used to form a complex with MetJ repressor (100 nM) and the resultant mixture analysed by gel retardation. Unshifted (U) and complexed (C) DNA was then eluted from the gel, modified phosphates were cleaved and then analysed on a 20% polyacrylamide gel alongside a Maxam and Gilbert sequencing ladder (top strand is shown). The two phosphates where ethylation leads to complete exclusion from the repressor–operator complex are indicated by arrows. *e*, Summary of footprinting and protection data on the 32-bp anti-met-box construct shown as a space-filling representation of an idealized 10-fold B-DNA duplex. The extent of the region protected from MPE cleavage (~18 bp) is indicated by arrows. The non-esterified phosphate oxygens which lose more than 10% of their surface accessibility based on the model of the complex shown in Fig. 3 of ref. 3 (this issue) are indicated by shading. ★, Phosphates identified in Fig. 4*d*; ●, central dyad between the two met boxes.

nucleotide as determined from the conservation table (Table 1). To discriminate between the two alignments we constructed an operator fragment containing the perfect 16-mer consensus oligonucleotide embedded symmetrically between two such anti-met-boxes; this construction might be expected to minimize binding in the flanking sequences. Gel retardation analysis of this construct reveals a single retarded species under conditions that produce the largest retarded complex in the pUC18 construct (Fig. 4*b*). At very high repressor concentrations, even this construct resulted in three retarded species. A simple interpretation of these data is that the single retarded species is a complex between a single repressor dimer and the DNA fragment. Symmetry arguments would then suggest that the repressor 2-fold axis of symmetry must be aligned with the unique 2-fold axis of symmetry between met boxes. We have determined the region footprinted by the repressor in this complex by using the reagent methidium-propyl-EDTA-Fe (MPE)[16] (Fig. 4*c*). Densitometry of autoradiographs of these footprints is consistent with a short region of protein–DNA interaction centred, on a helical projection of the operator site, about the sequence 5′-dCTAG-3′, that is, about the junction between the met boxes.

Constructs produced with the alternative binding site, that is, a 4-bp shifted sequence and its equivalent anti-met-box site, have lower affinities for MetJ, as judged by both filter-binding and gel retardation assays, than do the sites described here (data not shown).

To confirm the position of the repressor dyad relative to those in the operator, we performed phosphate-ethylation interference experiments[12] on the complex formed with the anti-met-box construct (Fig. 4*d*, *e*). The positions of close contact between protein and DNA identified in this way show excellent correlation with other complex structures determined by X-ray crystallography[17]. Four such phosphates are identified in the MetJ–SAM–anti-met-box construct. These are shown projected onto a DNA helix in Fig. 4*e*. As expected from the MPE-footprinting data, the contacts are symmetrically disposed across the dyad between the two met boxes. The size of the ethylation footprint is consistent with the binding of a single dimer at this site. Surface accessibility calculations of the model in which a single MetJ dimer is docked to a B-form DNA duplex via the C-helices[3] (in alignment 1), correlate well with the protection of these four phosphates. We note, however, that the alternative β-strand model could account for these results if two repressor dimers were bound according to alignment 2. Although the stoichiometry of this complex remains to be determined, the balance of the data so far indicates that the first explanation is correct.

We have interpreted the cooperativity of repressor binding in terms of protein–protein interactions; a second explanation, however, also seems possible. Binding of one repressor dimer could alter the conformation of the DNA site in such a way as to facilitate binding of adjoining repressors. In the perfect consensus site the centre of the operator sequence is —CTAG—. The finding that nucleotide steps of TA in oligonucleotide crystals and the *trp* repressor–operator complex[18] induce DNA bending towards the major groove could support this argument. None of the naturally occurring *met* operators, however, contains the sequence 5′-CTAG-3′.

Comparison to *trp* repressor

Structural work most comparable to ours with an *E. coli* metabolic repressor has been with the *trp* repressor. This repressor is also a stable dimer in solution, having intertwined regions of polypeptide. It differs, however, from MetJ in that it has a 'classical' helix-turn-helix DNA-binding motif, and also in that the binding of corepressor results in a large coordinate conformational change around this DNA-binding region[9,19]. Analysis of the natural *trp* operators does not immediately reveal obvious tandem repetitions. But recently, Gunsalus *et al.*[20,21] proposed tandem-repressor-binding for the *trp* repressor on the basis of methylation- and nuclease-protection data, although the possibility of cooperativity in terms of protein–protein interaction was not discussed. Footprinting data for the *trp* repressor on natural operators indicate that more than one repressor must be bound[14,21,22] and there is a report of an 8-bp repeat in the bound complex[23].

Remarkably, the *trp* operators contain as consensus elements a sequence that matches the met-box consensus sequence, that is, the repeat dAGNNNNCT (N is an unspecified nucleoside). Indeed, it is possible to analyse the naturally occurring *trp*-operator regions in terms of 'trp boxes' analogous to met boxes, that is, as several 8-bp repeats with similar dyad symmetry. This raises the possibility that *met* and *trp* operators have evolved from a common ancestor, even though their respective repressor proteins are structurally unrelated and operate differently. In fact, Sigler *et al.*[18] report that the structure of the *trp* repressor complexed with a symmetrized DNA fragment that contains a portion of a natural operator site is not inconsistent with a similar model for tandem binding.

The tandem-binding models discussed here may be of general relevance for other gene regulatory proteins that seem to recognize tandem sites that do not contain 2-fold symmetry. □

Muscle-specific gene expression controlled by a regulatory element lacking a MyoD1-binding site

T. J. Baldwin & S. J. Burden

Biology Department, 16-820 Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Muscle-specific expression of the gene encoding the delta subunit of the acetylcholine receptor is controlled by a 54-base-pair region that does not contain a binding site for MyoD1, a protein involved in activation of the myogenic program. A MyoD1-binding site is present in the proximal promoter region of the gene encoding the δ-subunit, but is neither sufficient nor necessary for muscle-specific expression in transfected muscle cells.

THE analysis of the regulation of skeletal muscle genes provides a particularly useful system in understanding mechanisms that are responsible for cell-type-specific gene expression. In particular, identification of MyoD1 and myogenin, gene products that are capable of altering the fate of mesodermal cells and activating the myogenic phenotype, provides one of the clearest examples in vertebrates of genes that are critical for early decisions in cell determination and differentiation[1-3]. Although it is not clear how expression of MyoD1 and myogenin results in subsequent activation of genes that are specifically expressed in skeletal muscle cells, it has been suggested that MyoD1 may interact directly with these genes and activate transcription[1].

We have characterized the regulatory region of the murine acetylcholine receptor (AChR) δ-subunit gene by transfection assays and identified a 54-base pair (bp) region of 5′ flanking DNA that is necessary and sufficient for muscle-specific gene expression. In addition, we identify a MyoD1-binding site in the δ-subunit gene. This MyoD1-binding site is not in the 54-bp region and not required for muscle-specific gene expression.

We demonstrate that nuclear proteins from myotubes, but neither myoblasts nor fibroblasts, bind to the 54-bp regulatory region and that these myotube-specific DNA-binding activities do not contain MyoD1. These studies demonstrate that DNA-binding activities, which are distinct from MyoD1, interact with a regulatory element that controls muscle-specific expression, and raise the possibility that these activities are critical for muscle-specific gene expression. In addition, we discuss possible roles for the MyoD1-binding site in the δ-subunit gene that are distinct from simple transcriptional activation.

Cis-acting regulatory element

Deletions of the δ-subunit gene were analysed to identify sequences that are necessary for muscle-specific expression. These constructs were transfected into C2 myoblasts or 3T3 cells and expression analysed in C2 myoblasts, C2 myotubes that had differentiated from the transfected C2 myoblasts, or in 3T3 cells. We demonstrated previously that nucleotides −148 to +24 of the δ-subunit gene are sufficient to confer cell-type and differentiation-dependent expression[4]. Deletion from nucleotide −148 to nucleotide −128 resulted in a 16-fold decrease in expression and deletion to nucleotide −107 resulted in a further 3-fold decrease (Fig. 1*a*; Table 1). Expression from nucleotides −148 to +24 was ~100-fold greater in C2 myotubes than 3T3 cells, whereas expression from nucleotides −107 to +24 was equivalent in the two cell types (Table 1). Nucleotides −148 to −108 are therefore necessary for myotube-specific gene expression.

To determine whether the region identified as necessary for muscle-specific expression is also sufficient, we constructed chimaeric promoters containing regions of the δ-subunit gene fused to the c-*fos* basal promoter (FBP). This promoter contains a TATA element, a transcription start site, but lacks the serum response element[5] and is an equally poor promoter in fibroblasts, myoblasts and myotubes (Fig. 1*b*; Table 1).

Fusion of nucleotides −148 to −53 from the δ-subunit gene immediately 5′ to the FBP conferred myotube-specific expression on the FBP (Fig. 1*b*; Table 1). Deletion of nucleotides

TABLE 1 Nucleotides −148 to −95 are necessary and sufficient to confer myotube-specific expression

(n=4–6)			

The activity of chloramphenicol acetyl transferase (CAT) in cultures transfected with nucleotides −148 to +24 of the δ-subunit gene was arbitrarily assigned as 100% and corresponds to 86% conversion of labelled chloramphenicol to its acetylated derivatives. The mean activity and the standard error of the mean from four to six separate assays are presented. The construct −150/−107–FBP was made by cloning a double-stranded oligodeoxynucleotide extending from nucleotides −150 to −107 of the δ-subunit gene into the FBP–CAT vector described in the legend to Fig. 1. The sequence of this construct was verified by direct DNA sequencing[18]. Cells transfected with FBP and stimulated with serum are referred to as FBP, s.s.[19]. There is a higher level of expression from the δ-subunit gene promoter in myoblasts than 3T3 cells, which is probably because of incipient differentiation of myoblasts. Nevertheless, deletion of nucleotides −148 to −129 results in a small increase of expression in 3T3 cells, but not in myoblasts. We have not investigated whether this increase in expression in 3T3 cells arises from removal of sequences involved in repression in 3T3 cells or from inadvertently placing activating plasmid sequences in proximity to the δ-subunit gene basal promoter. Nevertheless, the maximal level of expression in 3T3 cells transfected with nucleotides −128 to +24 is 25-fold lower than expression in myotubes transfected with nucleotides −148 to +24. The orientation of DNA from the δ-subunit gene that was placed 3′ to the CAT-encoding sequence was determined by DNA sequencing[13]. The orientation of the three copy insert of nucleotides −148 to −95 is −148 to −95, −148 to −95 and −95 to −148. The SV40 enhancer (SVE)[10,20] is oriented 3′-to-5′ as determined by mapping with *Nco*I. ND, not determined.

−96 to −53 of the δ-subunit gene did not diminish expression significantly, whereas further deletion to nucleotide −107 resulted in a 30-fold decrease in expression (Fig. 1*b*; Table 1). Nucleotides −148 to −95 are sufficient, and nucleotides −106 to −95 are necessary, to confer myotube-specific expression.

Nucleotides −148 to −95 activated transcription equally well in either orientation when positioned immediately 5′ of the FBP (Table 1). Although we have not investigated the position-dependency in detail, neither single nor multiple copies of the 54-bp element activated expression when positioned ~1.7 kilobases (kb) 3′ to the δ-subunit basal promoter (Table 1). The δ-subunit basal promoter retained functional promoter capabilities, however, because addition of the SV40 enhancer activated transcription 30-fold from the basal promoter of the δ-subunit gene in fibroblasts and myotubes (Table 1).

Sequence motif in the 54-bp element

Because expression studies demonstrate that both nucleotides −148 to −129 and −106 to −95 are necessary for myotube-specific expression (Table 1) and binding studies demonstrate that myotube nuclear proteins bind to both the 5′ and 3′ region of the −148 to −95 sequence (see below; Fig. 2), we examined the DNA sequence of the 54-bp element to determine whether a similar motif is present both in 5′ and 3′ portions of the −148 to −95 sequence. Indeed, an imperfect repeat of seven nucleotides, TGCCTGG, occurs four times in the 54-bp element (Table 2). A single copy of this sequence is present in the myotube-specific regulatory region of the gene for the chicken AChR alpha-subunit[6,7] and two copies in the murine creatine kinase gene[8] (Table 2). Nevertheless, this motif is not apparent in the important regulatory region of the skeletal muscle actin gene[9] or in the myotube-specific enhancer located 3′ to the rat myosin light-chain 1/3 gene[10]. Furthermore, this motif alone is not sufficient to confer myotube-specific expression, because mutated δ-subunit genes that maintain either one copy of the motif (construct −148/−140 FBP-CAT) or three copies of the motif (construct −128/+24-CAT) did not confer myotube-specific expression. Nevertheless, it is interesting that a single linker substitution in the murine creatine kinase gene that alters both the MyoD1-binding site and one of the motifs described above virtually abolishes myotube-specific expression[8].

Binding of myotube nuclear protein to 54-bp element

We used an electrophoretic mobility shift assay (EMSA) to determine whether nuclear proteins expressed in myotubes bind to the 54-bp element. Nuclear proteins from C2 myotubes bound to nucleotides −148 to −95 and formed one major and three minor protein-DNA complexes (Fig. 2). Because competition with unlabelled −148 to −95 DNA inhibited the appearance of each shifted band, whereas competition with unlabelled plasmid DNA caused only a small reduction in protein-DNA complexes, each shifted band arises from a sequence-specific interaction of nuclear protein(s) with the 54-bp element. It is of interest that nuclear protein(s) from C2 myotubes bound to either nucleotides −148 to −129 or −129 to −95 (Fig. 2). Furthermore, because nucleotides −148 to −140 compete partially with nucleotides −148 to −95 for binding of nuclear proteins, at least part of the sequence that these nuclear proteins recognize is contained within the TGCCTGG motif.

Nuclear proteins isolated from undifferentiated C2 myoblasts and 3T3 cells also bound to the 54-bp element (Fig. 2). It is important to note that the electrophoretic mobility of the shifted-bands detected with extracts from differentiated myotubes was different from that detected with myoblast extracts. Furthermore, because nucleotides −129 to −95, but not nucleotides −148 to −129, compete efficiently for binding, nuclear proteins from myoblasts bind to the 3′ region, but not the 5′ region of the 54-bp element.

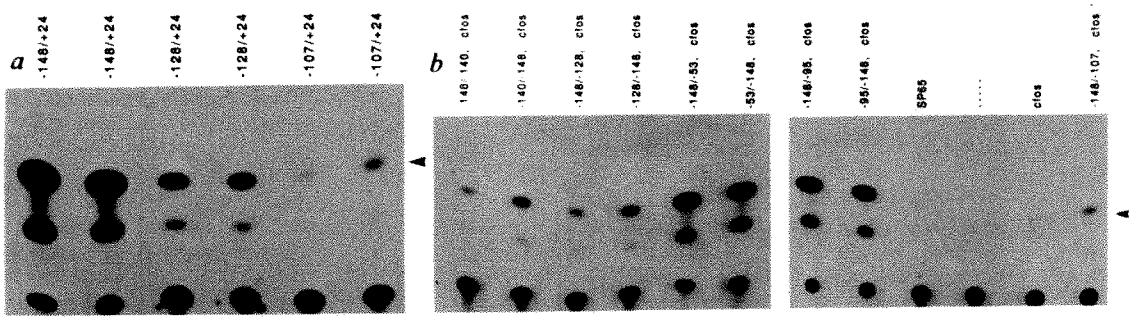

FIG. 1 Nucleotides −148 to −95 of the murine AChR δ-subunit gene are necessary and sufficient to confer myotube-specific expression. *a*, Autoradiogram of TLC fractionation of the reaction products in a CAT assay from transiently transfected C2 myotubes demonstrates that CAT activity is present in myotubes transfected with nucleotides −148 to +24 of the δ-subunit gene, but that 16-fold and 50-fold lower levels of CAT activity are present in myotubes transfected with nucleotides −128 to +24 and −107 to +24 of the gene, respectively. The results from duplicate transfections are illustrated. *b*, Autoradiogram of TLC fractionation of the reaction products in a CAT assay from transiently transfected C2 myotubes demonstrates that CAT activity is present in myotubes transfected with chimaeric promoters containing either nucleotides −148 to −53 or −148 to −95 of the δ-subunit gene in either orientation, immediately 5′ to the c-*fos* basal promoter (FBP). Transcription from the chimaeric promoter is also accurate, because transcription from the normal c-*fos* gene and the chimaeric promoter initiate at the same nucleotide (unpublished results). CAT expression from the FBP is low (cfos), but greater than the level of CAT activity observed in non-transfected myotubes (−) or myotubes transfected with a plasmid lacking a promoter (SP65). Slightly elevated levels of CAT activity are present in myotubes transfected with chimaeric promoters containing nucleotides −148 to −140, −148 to −128, and −148 to −107 upstream of FBP. The arrowheads indicate the position of 3-mono-acetylated chloramphenicol. The TLC plates were exposed to X-ray film at room temperature overnight.

METHODS. The methods used to generate 5′ deletions of the δ-subunit gene with *Bal*31 nuclease have been described previously[4]. Constructs containing 148, 128 or 107 bp of 5′ flanking DNA also contain 24 bp of 5′ untranslated region and were fused to the coding region of the CAT gene as described[4]. To construct the chimaeric promoters, an *Eco*RI–*Hin*dIII cassette containing δ-subunit-gene nucleotides −148 to +24 was cloned into *Eco*RI and *Hin*dIII digested pGEM-3. The DNA was linearized with *Hin*dIII, partially digested with *Bal*31 and then digested with *Eco*RI. T4 DNA polymerase was used to produce blunt ends and *Sal*I linkers were ligated to blunt-ended DNA. The 3′ deleted DNAs were digested with *Sal*I, purified and cloned into a plasmid containing a unique *Sal*I site immediately 5′ to the basal promoter of the murine c-*fos* gene containing nucleotides −56 to +109 from the c-*fos* gene[5]. Plasmids containing δ-subunit sequences 3′ to the CAT gene were constructed by isolating δ-subunit sequences from the chimaeric promoters described above and cloning these *Sal*I fragments into a unique *Sal*I site 3′ to the CAT coding sequence in the SP65-(−107/+24)-CAT construct. DNA was transfected as a calcium phosphate precipitate[4,21]. We co-transfected cells with a plasmid containing the human growth hormone (HGH) gene[22] and normalized CAT expression to a constant level of secreted HGH[4]. HGH activity varied less than twofold between the two different cell lines, and there was less than two-fold variation in HGH activity in different experiments in any one cell line. The assays were quantitated by excising radioactive cloramphenicol and its acetylated derivatives from TLC plates and measuring the radioactivity by scintillation counting[4].

TABLE 2 The TGCCTGG motif

A motif is repeated in the myotube-specific regulatory region of the δ-subunit gene and present in the regulatory region of other genes expressed in skeletal muscle. Genes which contain TGCCTGG in their myotube-specific regulatory region are indicated[6–8]; the sequence of the motif and the position of the motif in each gene are indicated. The location of this motif in nucleotides −150 to −95 of the δ-subunit gene is shown.

MyoD1 does not bind to the 54-bp element

MyoD1, a nuclear protein that has sequence similarity with the *myc* family of DNA-binding proteins[1,11], is a skeletal muscle-specific gene product that can trigger the differentiation of 10T1/2 cells and alter the differentiation of fibroblast lines to a myogenic phenotype[1]. We were interested in determining whether the δ-subunit gene contains a binding site for MyoD1 and, if so, whether the binding site is in the 54-bp myotube-specific regulatory region.

We identified such binding sites by EMSA. The MyoD1 protein used in these assays was a recombinant protein between MyoD1 and glutathione S-transferase (MyoD1-glu)[12]. The MyoD1-glu protein binds to a DNA fragment extending from nucleotide −148 to +24 of the δ-subunit gene (Fig. 3). The binding of MyoD1-glu was competed efficiently with unlabelled −148 to +24 DNA and with DNA from the 3′ region (nucleotides −95 to +24), but not the 5′ region (nucleotides −148 to −95) (Fig. 3). MyoD1 therefore binds to DNA sequences between nucleotides −95 to +24, but not to 54-bp element.

The MyoD1-binding site was mapped more precisely by methylation interference footprinting assays[13]. These studies demonstrate that methylation of guanosine residues −23, −22, −17 and −15 interfere with the binding of MyoD1, whereas methylation of guanosine residue −19 enhances MyoD1-binding (Fig. 4). The MyoD1-binding site in the δ-subunit gene therefore extends from nucleotides −23 to −15.

Expression and the MyoD1-binding site

The expression studies along with the binding studies that we have described demonstrate that a MyoD1-binding site is not sufficient to confer myotube-specific expression, because nucleotides −107 to +24 of the δ-subunit gene retain the MyoD1-binding site, yet do not confer myotube-specific expression. Nucleotides −107 to +24, however, retain functional promoter

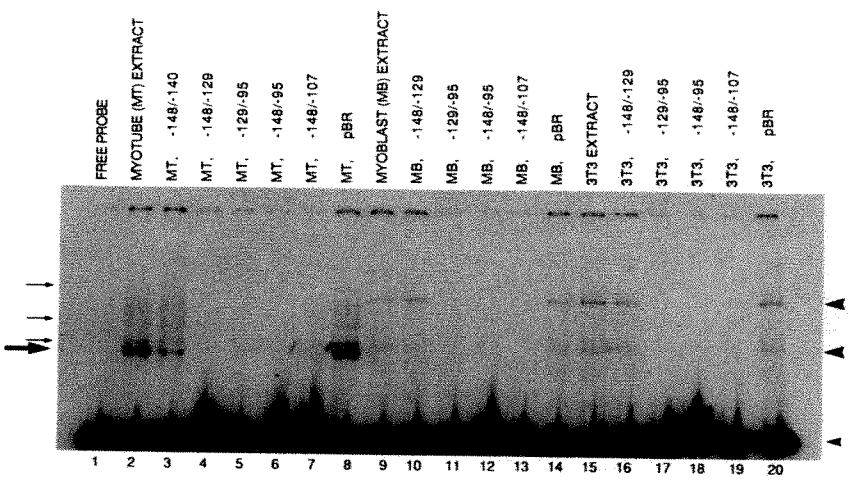

FIG. 2 Nuclear proteins from C2 myotubes bind to nucleotides −148 to −95 in the δ-subunit gene. One major (thick arrow) and several minor shifted-bands (thin arrows) are detected in binding assays of nuclear proteins from C2 myotubes and nucleotides −148 to −95. Binding is competed partially with nucleotides −148 to −140 and completely with nucleotides −148 to −95, −148 to −107, −148 to −129 and −128 to −95. No competition is detected with 1 μg *Msp*I-digested pBR322 DNA. Two minor shifted-bands (large arrowheads) are detected in binding assay of nuclear proteins from either C2 myoblasts or 3T3 cells and nucleotides −148 to −95. Binding is competed completely with nucleotides −148 to −95, −148 to −107, and −128 to −95. No competition is detected with nucleotides −148 to −140, −148 to −129 or pBR322 DNA. Three micrograms of nuclear protein was included in each assay and competition assays included a 100-fold molar excess of purified competitor DNA. The position of free DNA probe is indicated with a small arrowhead.

METHODS. Nuclear extracts from C2 myotubes, C2 myoblasts and NIH 3T3 cells were prepared essentially as previously described[23]; the solubilization buffer, however, included leupeptin (10 μg ml^{-1}) and aprotinin (10 μg ml^{-1}). C2 myoblasts were collected at 20–30% confluence and NIH 3T3 cells at ~80% confluency. Differentiation of C2 myotubes was initiated by growing 70–80% confluent C2 myoblasts in 5% adult bovine serum for three days and subsequently in 5% adult bovine serum medium supplemented with cytosine arabinoside (10^{-5} M) for two days to minimize growth of myoblasts. Five days after induction of differentiation the C2 myotubes were collected. Labelled DNA fragments were prepared by digesting pGEM-(−148/+24) DNA with *Eco*RI and end-labelling with [α-^{32}P]dATP (6,000 Ci mmol^{-1})[24]. The DNA was subsequently digested with *Hin*dIII and labelled DNA (nucleotides −148 to +24) was isolated by PAGE. After digestion with *Hph*I and gel electrophoresis, labelled DNA (nucleotides −148 to −95) was isolated (10^7–10^8 c.p.m. μg^{-1}) and used in EMSA. EMSA with nuclear extracts was performed in 10-μl reactions containing 5,000 c.p.m. (0.1 ng) labelled DNA and 3 μg nuclear extract protein (in 40 mM KCl, 2 mM $MgCl_2$, 1 mM EDTA, 8% glycerol, 10 mM Tris buffer, pH 7.4 and 1 μg poly(dI-dC)·poly(dI-dC)[25–27]. The reactions were at 22 °C for 15 min. Free DNA and protein–DNA complexes were separated by PAGE (150 V; 4% acrylamide, 22 mM Tris buffer, 22 mM boric acid and 0.5 mM EDTA pH 8.0). DNA fragments used in competition assays were purified from plasmids containing the relevant fragment and were added to the labelled DNA fragment before addition of nuclear extract.

capabilities, as addition of the SV40 enhancer to a construct containing these nucleotide elevates expression in both muscle and fibroblasts (Table 1).

Similarly, a MyoD1-binding site is not necessary for muscle-specific expression in these transfection assays, because a chimaeric promoter between the 54-bp element and the FBP does not contain a MyoD1-binding site (Fig. 3*b*) yet confers muscle-specific expression (Table 1).

Discussion

We have demonstrated that a 54-bp region of 5′-flanking DNA from the gene for the δ-subunit of the murine AChR is necessary and sufficient for muscle-specific gene expression. Deletion of this sequence results in a 50-fold decrease in expression in myotubes, and fusion of this sequence immediately 5′ to the c-*fos* basal promoter confers myotube-specific expression on an otherwise weak, non-tissue-specific promoter.

MyoD1 does not bind to the 54-bp region. Indeed, preliminary experiments indicate that the four binding activities that do bind to the 54-bp element do not contain MyoD1: antibodies against MyoD1 react with MyoD1-glu, but not with the activities in C2 nuclear extracts that bind to the 54-bp element.

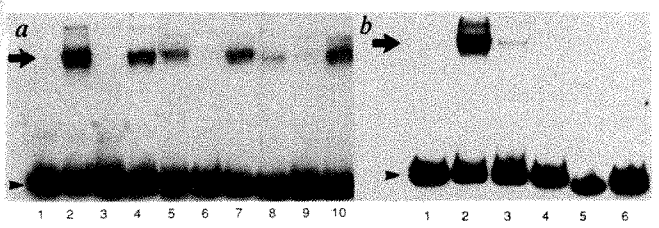

FIG. 3 MyoD1 binds to a region of the δ-subunit gene that is neither necessary nor sufficient for myotube-specific expression. *a*, MyoD1 binds to nucleotides −95 to +24, but not −148 to −95 of the δ-subunit gene. The probe is ^{32}P-end-labelled DNA (nucleotides −148 to +24) of the δ-subunit gene. The position of free DNA (lane 1) is indicated with an arrowhead. Incubation of labelled DNA with the MyoD1-glu recombinant protein results in a distinct shifted band (lane 2; arrow), whereas incubation with glutathione S-transferase does not result in a shifted-band (lane 3). One hundredfold molar excess of unlabelled δ-subunit DNA (nucleotides −148 to −95) reduces binding by about twofold (lane 4); because pBR DNA also reduces binding by approximately twofold (lane 10), this competition is considered sequence nonspecific. By contrast, 10-fold (lane 5) and 100-fold (lane 6) molar excess of an oligodeoxynucleotide containing the murine creatine kinase MEF1-binding site compete for binding to the ^{32}P-end-labelled probe. Similarly, 10-fold (lane 8) and 100-fold (lane 9) molar excess of the δ-subunit DNA (nucleotides −95 to +24) compete for binding to ^{32}P-end-labelled probe. An equal molar quantity of δ-subunit DNA (nucleotides −95 to +24) (lane 7) and 1 μg *Msp*I-digested pBR322 DNA (lane 10) reduce binding by approximately twofold. *b*, MyoD1 does not bind to the c-*fos* basal promoter (FBP). The DNA probe in lanes 1–4 is ^{32}P-end-labelled δ-subunit DNA (nucleotides −148 to +24) and in lanes 5 and 6 is ^{32}P-end-labelled c-*fos* DNA (nucleotides −56 to +109). The position of free DNA (lanes 1 and 5) is indicated with an arrowhead. Incubation of labelled δ-subunit DNA probe with MyoD1-glu results in a distinct shifted band (lane 2; arrow) that is competed with a 10-fold (lane 3) and 100-fold (lane 4) molar excess of unlabelled δ-subunit DNA (nucleotides −148 to +24). MyoD1 does not bind to FBP because incubation of labelled c-*fos* DNA probe with MyoD1-glu does not result in a shifted band (lane 6). The dried gel was exposed to X-ray film with an intensifying screen overnight at −70 °C.

METHODS. pGEM-(−148/+24) DNA was labelled as described in Fig. 2. The double-stranded oligodeoxynucleotide representing the MEF1-binding site extends from nucleotides −1,138 to −1,117 in the murine creatine kinase gene[8]. EMSA with MyoD1-glu was performed in 20-μl reactions containing 5,000 c.p.m. (0.1 ng) labelled DNA and 10 ng MyoD1-glu protein, or 10 ng of glutathione S-transferase (in 50 mM KCl, 3 mM $MgCl_2$, 1 mM EDTA, 1 mM DTT, 0.5% Nonidet P-40 or NP-40, 10 μg ml^{-1} BSA, 10% glycerol, 20 mM HEPES buffer, pH 7.6 and 5 μg ml^{-1} of poly(dI-dC)·poly(dI-dC). Free DNA and protein–DNA complexes were separated by PAGE (6% acrylamide, 22 mM Tris buffer, 22 mM boric acid and 0.5 mM EDTA, pH 8.0). Fragments used in competition assays were purified from plasmids containing the relevant fragment and added to the labelled DNA fragment before addition of nuclear extract.

It is possible that myogenin, rather than MyoD1 is required for muscle-specific expression of the δ-subunit gene by binding to the 54-bp element. Consistent with this idea, the BC3H1 smooth-skeletal muscle cell line expresses AChR[14] and myogenin[2], but not MyoD1[1]. Nevertheless experiments indicate that nuclear extracts from C2 myotubes contain an activity that binds to the MyoD1-binding site (oligodeoxynucleotide of nucleotides −29 to −15) and that this activity reacts with

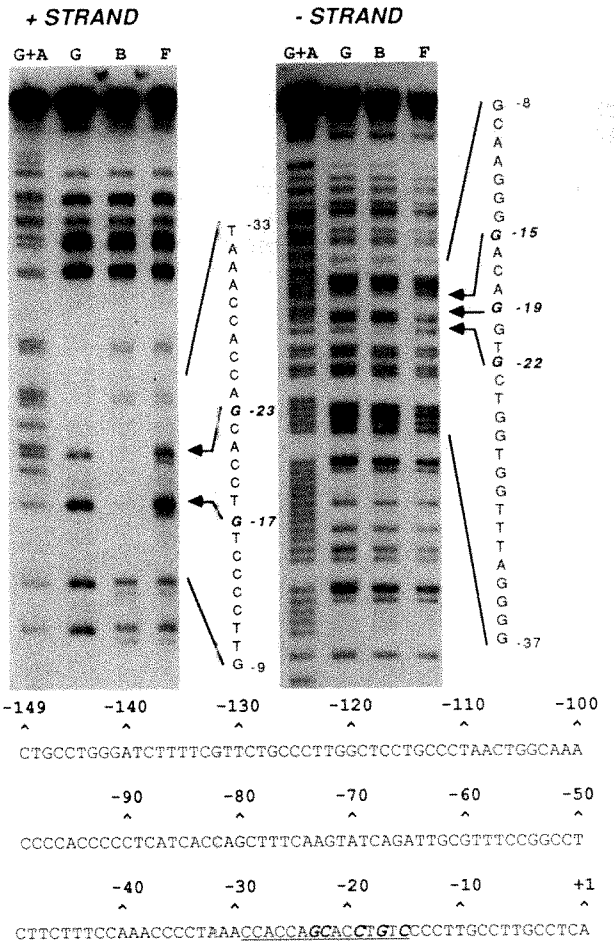

FIG. 4 Nucleotides −23 to −15 of the δ-subunit gene are involved in MyoD1 binding. Methylation of guanosine residues −17 and −23 on the (+) strand and −15 and −22 on the (−) strand interferes with MyoD1 binding, whereas methylation of guanosine residue −19 on the (−) strand enhances MyoD1 binding. The sequence of the δ-subunit gene from nucleotides −149 to +1 is illustrated. Residues identified by methylation interference are in bold and italics; the position of the methylated nucleotide that enhances MyoD1 binding is indicated with an asterisk. Ethylation of residues −29 to −15 (underlined) interferes with MyoD1 binding (unpublished observations). Products of Maxam–Gilbert sequencing reactions with free DNA are denoted by G + A and G. B and F are products of Maxam–Gilbert G-specific sequencing reactions with partially methylated DNA either complexed with MyoD1 (B) or free (F).

METHODS. The probe used for methylation interference footprinting contained sequences −107 to +24 of the δ-subunit promoter. The upper strand was labelled by digesting SP65-(−107/+24)-CAT DNA with *Hin*dIII and labelling the ends with [α-^{32}P]dATP; after digestion with *Eco*RI, the labelled fragment from the δ-subunit gene was purified from polyacrylamide gels. The lower strand was labelled in a similar manner except that the DNA was digested first with *Eco*RI and subsequently with *Hin*dIII. End-labelled DNA was methylated with dimethylsulphate as described[13]. Partially methylated DNA (5×10^6 c.p.m.) was included in an EMSA containing 0.5 μg MyoD1-glu and the bound and free DNA were excised from 4% polyacrylamide gels and isolated after chromatography on Elutip columns (Schleicher and Schuell, Keene, New Haven). The purified DNA was cleaved with piperidine[13] and the products resolved in an 8% polyacrylamide–7M urea gel. The gels were fixed, dried and exposed overnight to X-ray film at −70 °C with an intensifying screen.

antibodies to myogenin; furthermore, these antibodies do not react with the activities that bind to the 54-bp element (T.J.B., S.J.B. and Wright, W. E., unpublished results). Moreover, the 54-bp element does not compete with the MyoD1-binding site in binding assays. Neither MyoD1 not myogenin alone can thus account for muscle-specific expression conferred by the 54-bp element.

Our MyoD1-binding assays may not have reflected the *in vivo* assembly state of MyoD1. Indeed, recent studies demonstrate that MyoD1 can form a heterodimer with either immunoglobulin-enhancer binding proteins E12 or E47 *in vitro*; importantly, these heterodimers bind a sequence similar to the MyoD1 binding site defined in our study with recombinant MyoD1-glu[15]. Independent, therefore, of whether MyoD1, myogenin or heterodimes of MyoD1 or myogenin complexed with more general transcription factors bind to this site *in vivo*, we conclude that this site is neither required nor sufficient for muscle-specific expression in these transfection experiments.

What is the role of the MyoD1-binding site in the δ-subunit gene and in other genes that are expressed in skeletal muscle? A MyoD1-binding site may be dispensable in the δ-subunit gene and have a direct role in regulating expression of other genes expressed in skeletal muscle. In this regard, it is noteworthy that fusion-arrested myoblasts express AChR but do not express a variety of proteins associated with the contractile apparatus[16,17]. Furthermore, C2 myoblasts transformed with activated *ras* or *fos* express little or no MyoD1, myogenin, myosin light chain and creatine kinase, but express reduced levels of desmin and nearly normal levels of AChR alpha subunit[28]. Expression of some skeletal muscle genes could thus be regulated by a MyoD1-myogenin-dependent pathway, whereas other genes could be regulated by a separate pathway and involve activities that bind to the 54-bp element. By contrast, the MyoD1-binding site in the δ-subunit gene may have a role that was not detected in our assays. The MyoD1-binding site may play a part earlier in muscle development and is not detected in transfection assays of myoblasts and myotubes. Analysis of stably transfected cell lines or transgenic mice may distinguish among some of these possible functions of a MyoD1-binding site. Nevertheless, the results presented here indicate that a MyoD1-binding site in the δ-subunit gene has a function that is distinct from simple transcriptional activation. □

ACKNOWLEDGEMENTS. We thank Drs A. Lassar, R. Davis and H. Weintraub for providing recombinant MyoD–glutathione S-transferase, Mr Tau-Mu Yi for the oligodeoxynucleotide containing the MEF1-binding site in the murine creatine kinase gene, Dr K. Knight for advice about footprinting assays and Drs K. Walsh and N. Rosenthal for plasmids and for discussions. We thank Drs R. Lehmann, D. Baltimore and members of the laboratory for their critical reading ofthe manuscript. T.J.B. was supported by a postdoctoral fellowship from the Massachusetts affiliate of the American Heart Association. This work was supported by a research grant to S.J.B. from the Muscular Dystrophy Association.

Discovery of intergalactic radio emission in the Coma–A1367 supercluster

K.-T. Kim*, P. P. Kronberg*, G. Giovannini†‡ & T. Venturi‡

* Department of Astronomy, University of Toronto, Toronto, Ontario, Canada, M5S 1A7
† Dipartimento di Astronomia, via Zamboni 33, I-40100 Bologna, Italy
‡ Istituto di Radioastronomia, via Irnerio 46, I-40126 Bologna, Italy

THE Coma cluster is a rich cluster of galaxies nested in an even larger supercluster of galaxies. The plane of the supercluster seems to be defined by the Coma cluster itself and another galaxy cluster, Abell 1367, which lies ~40 Mpc farther west[1,2]. The largest structures known are the giant voids and superclusters which are as large as $70h_{75}^{-1}$ Mpc (refs 3–5). The Coma cluster of galaxies seems to be located on the rim of a giant void[6] in the three-dimensional distribution of galaxies. Here we describe the detection of faint, supercluster-scale radio emission at 326 MHz that extends between the Coma cluster of galaxies (Abell 1656) and the Abell 1367 cluster and which is apparently not associated with any individual galaxy system in the complex. The radiation's synchrotron origin implies the existence of a large-scale intercluster magnetic field with an estimated strength of 0.3–0.6 μG, which is remarkably strong. The synchrotron-emitting relativistic electrons cannot be older than a few times 10^8 yr, but we speculate that the magnetic field is the fossil of a pre-galactic primaeval field, which was amplified in the course of the formation of intergalactic voids and superclusters.

The Coma cluster of galaxies is visible at many wavelengths, from low radio frequencies to X-rays. It is thus an important testbed for large-scale phenomena in extragalactic astronomy. At radio frequencies, Coma is one of a few rich clusters that are known to have a diffuse halo. It has a steep radio spectrum, which is associated with non-thermal radio radiation from a population of 'old' relativistic electrons that are accelerated by a cluster-scale magnetic field[7–13].

We observed a portion of the Coma supercluster plane for a total of 72 h in May and June 1986 at 326 MHz, using the Westerbork Synthesis Radio Telescope (WSRT); for a description of the observing procedure see ref. 17. The observations were made in the redundancy mode[14] to increase the dynamic range. The data reduction was performed using the DWARF, NRAO-AIPS and CLEAN software packages. The synthesized beam of the final map was 2 × 1 arcmin elongated along the north–south axis and the r.m.s. noise level of the map is 1.1 mJy per beam. The useful field of view covers an area of 2.6° radius around the field centre.

We used further very-large-array observations at 327 MHz in the higher resolution A and B configurations centred both on

§ 326-MHz flux density (mJy), (G. G., unpublished data).

the cluster centre and on 1253+275, to find and subtract discrete sources present in the 'bridge' region. In particular, we have carefully subtracted the extended radio galaxies NGC4839 and NGC4827. The residuals are very small and we can rule out the possibility that the 'bridge' region is an artefact of the low-order interferometer spacings.

After removal of the small-diameter sources in this area, the remaining data were convolved to obtain a lower resolution (4×2 arcmin, elongated N–S) but higher signal-to-noise ratio for the diffuse emission. The resulting map (Fig. 1) has a dynamic range of ~2,200:1. The size of the 'bridge' is estimated to be ~50×20 arcmin (~$1.5h_{75}^{-1}$ Mpc in projection, where h_{75} denotes the use of 75 Mpc km^{-1}s^{-1} for the Hubble constant) and it is oriented along the axis defined by position angle about 50° (measured eastward from north). The total flux density S contained in the region is 760±100 mJy at 326 MHz. Table 1 contains a list of sources seen on or near the 'bridge'.

The large extent and especially the radio morphology of the 'bridge' implies that it is not the combination of numerous unresolved weak radio sources located in the same region, but that it is related to the extension of the cluster and, we suggest, a feature of the Coma–A1367 supercluster. The ability to distinguish such extended synchrotron emission is due to a combination of the high sensitivity and resolution at low frequencies of the recently extended WSRT. The resolution is comparable to a galaxy size at the distance of Coma and enables us to distinguish individual radio galaxies from the extended emission.

The shortest interferometer spacing D of the WSRT is 36 m. The missing interferometer spacings, <36 m, would produce a negative 'bowl' of a diameter of about λ/D, if there is such a large-scale radio feature present in the sky. At 326 MHz, this corresponds to a gaussian source with half-power beamwidth of ~1.5° Because the total extent of the diffuse emission in the map is comparable to the scale of the negative 'bowl', it is thus possible that some weak extended features could have remained undetected. To test for this, we measured the zero-level of the map at different regions well away from the 'bridge' region. Although it is very close to zero in the peripheral regions of the map, it becomes negative (down to −2 mJy) in the central region. This implies that some amount of flux was indeed missed because of the lack of short-spacing data in the observations. We estimate the total missing flux density in Fig. 1 to be 100 mJy; its presence would further reinforce the 'bridge' emission. No polarization information is available from the present data.

The 'bridge' emission has now been independently verified *a posteriori* in two previous maps of the Coma–A1367 supercluster region—the recent DRAO (Dominion Radio Astrophysical Observatory) data[13] at 408 MHz and the 430-MHz Aricebo telescope map[9].

We have reanalysed the former observations, made in April and May 1985 with a field centre at RA $12^h55^m30^s$, dec +27°55′. The sensitivity was 8 mJy per beam and the resolution at 408 MHz was 7.45×3.45 arcmin (elongated along the N–S axis.) Unlike the 326-MHz observations, single-dish data were available at 408 MHz from the Effelsberg Telescope[15], and these were added to the DRAO observations. Thus, this combined observation is complete to the longest spacing of 600 m. (K.-T. K., P. P. K., P. E. Dewdney and T. L. Landecker, manuscript in

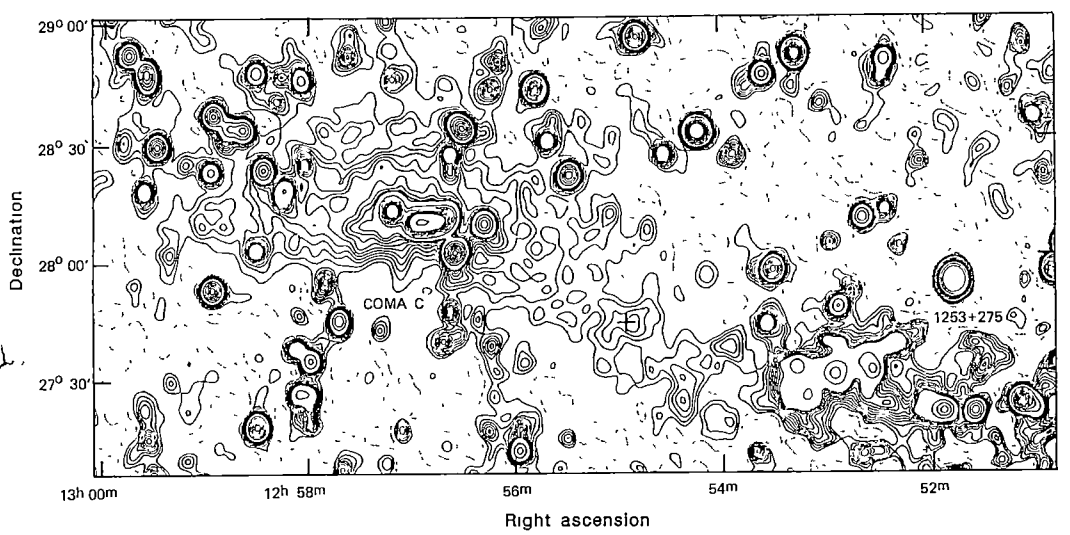

FIG 1 The Coma cluster of galaxies was observed with the WSRT at 326 MHz. Ten antennas were fixed, and the four moveable ones were set at B_s+n72 m where $n=0$ to 37, and B_s (the shortest baselines) were 35, 48, 60, 72, 84 and 96 for six separate 12-h sessions. The projected linear size of this source is ~$1.5h_{75}^{-1}$ Mpc. The location of NGC4839 is marked with a + symbol. The peak surface brightness is 9.1 mJy per beam. Contours are shown at −1, 1, 2, .. 9, 10, 20, 30, ..90, 100, 200, 400 times 4 mJy per beam.

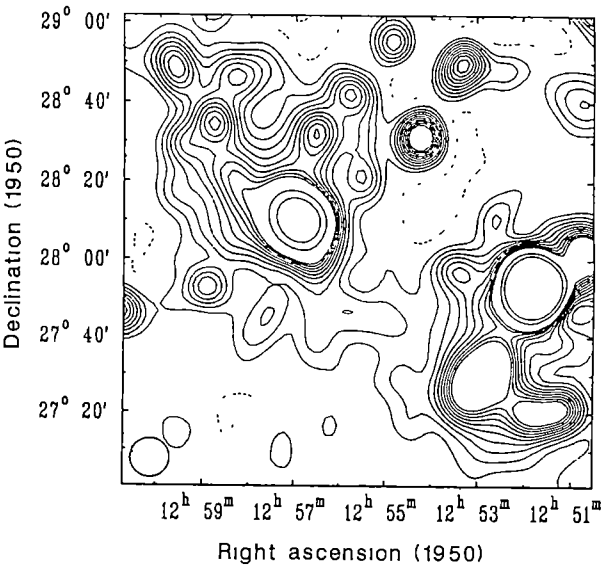

FIG. 2 The DRAO 408-MHz map of the Coma cluster, using data which includes the single-dish observations The synthesized beam is shown on the lower-left corner of the map Contour levels are $40\times(-1, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 20, 30)$ mJy per beam. Relatively strong small-diameter sources (1254+27W4, 1254+27W5, 1254+27W8, 1254+27W1 and a complex of sources to the south-east of Coma C) have been removed from this map

preparation).

Small-diameter sources, the position and fluxes of which are well determined from the WSRT map, were removed from the 'bridge' region, and the resulting map was convolved (final resolution 10 arcmin) to enhance the signal-to-noise ratio. To minimize the source-subtraction errors, only reasonably strong sources were removed from the DRAO map. They are 1254+27W4 (5C4.43), 1254+27W5, 1254+27W8 (5C4.50), 1254+27W1 (5C4.51) (see Table 1), in addition to a complex of sources to the south-east of Coma C. The resulting map is shown in Fig. 2. We estimate the 408-MHz bridge flux to be 600 ± 100 mJy.

Evidence for the 'bridge' emission is also suggested in the 430-MHz Arecibo telescope map[9], but the relatively low resolution and less certain beam and pointing characteristics did not make it possible to unambiguously ascribe the feature in that map to diffuse intergalactic emission. At 430 MHz, the total flux measured from the Arecibo telescope map is 600 ± 100 mJy. This is consistent with our estimates above (assuming a spectral index $\alpha=-1.5$), when we include the flux density missing from the 326-MHz WSRT map.

The physical parameters of the 'bridge' region can be estimated using the observed flux density and size at 326 MHz, $\alpha=-1.5$ ($S_\nu\propto\nu^\alpha$ where S_ν is the flux density at frequency ν) and the assumption of equipartition between the energy density of the relativistic protons and electrons and the magnetic field. If we also assume a volume-filling factor, ϕ, of unity, and a proton/electron ratio, k, of 1, the equipartition field strength is 0.3 μG if we model the 'bridge' as a cylinder 1,900 kpc long (allowing for some de-projection) and 800 kpc in diameter, and has a corresponding total energy of 1.4×10^{49} erg.

The 'dense' plane of the Coma supercluster may alternatively be a projection of a sheet-like boundary between the bubble surfaces around two spherical intergalactic voids[6]. In this case the magnetized region giving rise to the 'bridge' in Fig. 1 could have considerable depth d, along our line of sight. For the dimensions inferred from Fig. 1, $\alpha=-1.5$ and upper and lower synchrotron-radiation cutoff frequencies of 10 and 100,000 MHz, the equipartition magnetic field strength of the bridge can be expressed as

$$B_{\rm eq}=0.21\left(\frac{S}{0.75\ {\rm Jy}}\right)^{2/7}(1+k)^{2/7}\phi^{-2/7}\left(\frac{d}{1\ {\rm Mpc}}\right)^{-2/7}\ \mu{\rm G}\quad(1)$$

If the radiating volume increases by the (unknown) depth d, the associated equipartition magnetic field is lower by only $d^{-2/7}$. The equipartition field strength is similarly only weakly sensitive to ϕ and k. We note that $B_{\rm eq}$ will increase above 0.25 μG if the filling factor is less than unity, and/or if the energy density of intergalactic high-energy protons is significantly greater than that for the relativistic electrons.

Recent evidence from EXOSAT X-ray data[16] and from a study of extended radio galaxies near Coma A (ref. 17) indicate that the ambient intergalactic thermal pressure is sufficient to confine the bridge emission that we have detected. The radiating lifetime of a confined, synchrotron-emitting gas at 326 MHz ($E\approx10$ GeV) is $1\text{–}2\times10^8$ yr for magnetic field values in the range 0.2–0.6 μG, which is determined by synchrotron and, to a greater degree, inverse Compton losses that are due to scattering off microwave-background photons. We note that the inverse Compton mechanism might also be contributing to X-ray emission, in which case the implied thermal gas pressure could be somewhat lower.

The origin of these large-scale magnetic fields is not yet known. The field is probably much older than the trapped electrons, which are probably produced by the galaxy systems. The magnetic field that we are detecting is probably the amplified 'fossil' of a primordial magnetic field which may have played an important role in forming the giant voids and superclusters. The primordial magnetic field has been substantially amplified in the protogalactic medium as the galaxies and clusters evolved from their early state.

We assume, in the absence of turbulent field amplification, that the magnetic field on a large scale is characterized by the so-called 'frozen-in' field approximation. A compression of an originally smoothed-out protogalactic medium would change the strength of the primordial magnetic field B_0 to B through $B/B_0=(n/n_0)^\gamma$. Here n and n_0 are the particle number densities of the corresponding media, which are related to their linear dimensions through $n\propto l^{-3}$. The power-law index γ characterizes the 'frozen-in' field compression, which is typically known to vary between $\frac{1}{2}$ and $\frac{1}{3}$ in the interstellar medium[18]. If the intracluster magnetic field strengths result from the compression of a primordial magnetic field, the field strengths on cluster and galaxy scales, ($l\approx10$ kpc and 1 Mpc respectively) should differ by a factor $\geq10^2$. Taking the typical strength of a galactic magnetic field as 10^{-6} G, the intracluster magnetic field should, using this simple argument, be of the order of 10^{-8} G, and, in the region of the 'bridge', should be even smaller. This is clearly much less than the equipartition field strength inferred from the radio emission in the 'bridge' region, and supports the suggestion that substantial field amplification has occurred since the pre-galaxy epoch, that is, since the time when the voids were formed.

If the formation of the giant voids and superclusters was triggered by blast waves at an early stage of galaxy formation, such as in superconducting cosmic string theory[19–21] or cosmic explosions[22,23], the amplification of any weak primordial fields

should involve turbulence. Furthermore[24-26], if a turbulent intracluster magnetic field is generated in the wakes of galaxies, the magnetic energy is drawn from the kinetic energy of plasma motion. Mechanisms of this type are in any case much more efficient field amplifiers than straightforward field compression[27,28].

The large extent and the strength of the intergalactic magnetic fields revealed in Fig. 1 suggest that magnetic fields had a more important role than previously believed in the formation of galaxies and of larger hierarchical structures such as superclusters and voids. □

Low magnetic flux noise observed in laser-deposited *in situ* films of $YB_2Cu_3O_y$ and implications for high-T_c SQUIDs

THE first device made from a thin film of a high-transition-temperature (high-T_c) superconductor was a d.c. SQUID (superconducting quantum interference device)[1]. Many applications of SQUIDs demand high sensitivity at low frequencies $f(\leq 1$ Hz), and thus require films with low intrinsic '$1/f$' magnetic flux noise[2,3]. Although the level of $1/f$ noise in $Tl_2Ba_2Ca_2Cu_3O_x$ SQUIDs[4] is significantly lower than that in earlier $YBa_2Cu_3O_y$ (YBCO) SQUIDs[1], it remains higher than that in low-T_c devices. In post-annealed films of YBCO, the magnitude of the $1/f$ noise has been shown[5] to decrease dramatically as the quality of the films is improved. Here we report measurements of flux noise in a film of YBCO grown *in situ* by pulsed laser deposition (but not patterned into a SQUID). The $1/f$ noise level was two orders of magnitude lower than in our best post-annealed film. Provided that it proves possible to fabricate suitable low-noise Josephson junctions, a d.c. SQUID made from a film of this quality and operated at liquid-nitrogen temperature (77 K) should approach the low-frequency performance currently achieved in commerically available low-T_c SQUIDs.

The YBCO film was deposited on a (100) $LaAlO_3$ substrate using 30-ns pulses of 248-nm ultraviolet radiation from a KrF excimer laser[6,7] with an energy density of about 2 J cm^{-2} incident on a rotating stoichiometric target. The substrate was maintained at 650-750 °C to ensure *in situ* crystallization of the film in the ambient oxygen pressure of 0.2 torr. Figure 1 shows Rutherford backscattering spectra obtained from the as-grown film. These results indicate that the film has a thickness of 300 nm, the correct stoichiometry, nearly perfect c-axis alignment (as verified by X-ray diffraction), and a density of macroscopic defects comparable with bulk single crystals[8]. The critical current density in zero field, defined as the value at an electric field of 1 μV cm^{-1}, was 5×10^6 A cm^{-2} at 77 K and 2×10^7 A cm^{-2} at 4.2 K; these high values may be the result of strong flux pinning by microstructural defects[9]. Electron-microscope images revealed that the surface was very smooth (surface roughness < 5 nm) except for the presence of particles of ~1-μm diameter on the surface with a density of about one per 100 μm^2.

We measured the flux noise with a Nb-PbIn thin-film d.c. SQUID[10] attached to a sapphire plate maintained at 4.2 K inside a vacuum can[5]. The YBCO film was mounted on a thermally isolated hot stage parallel to and approximately 100 μm away from the SQUID. The temperature of the stage could be

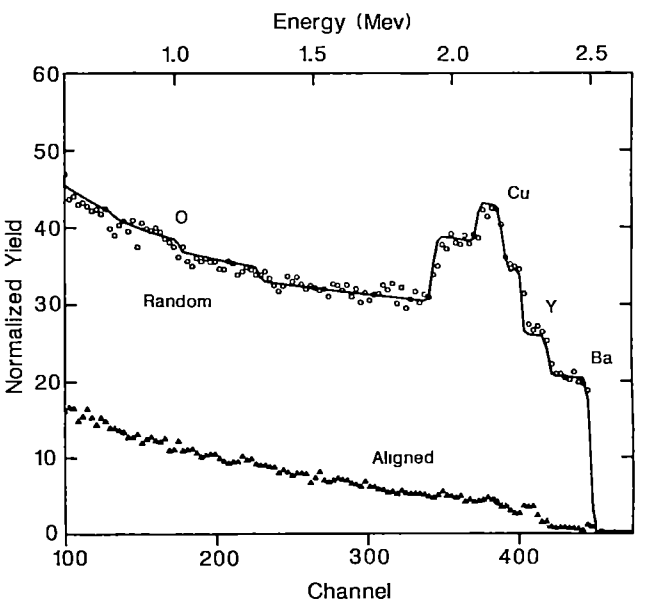

FIG 1 Random (upper curve) and channelling (lower curve) Rutherford backscattering spectra obtained with 2.8-MeV He^{2+} ions from the as-grown film of YBCO The fit to the random backscattering spectrum (solid line) corresponds to a film 300 nm thick and with correct stoichiometry. When the ion beam is aligned with the substrate (100) direction, the number of backscattered ions drops substantially The ratio of backscattered yield from random and aligned spectra measured just below the Ba surface peak, about 3%, is similar to that obtained for single crystals

§ To whom correspondence should be addressed

regulated at any value between 4.2 and 140 K. Magnetic flux noise in the YBCO film was inductively coupled to the SQUID with an efficiency of ~70%. We determined the critical temperature of the film by measuring the applied magnetic field B_0 required to produce one flux quantum (ϕ_0) in the SQUID; the diamagnetic screening of the superconducting film increased the value of B_0 over that in the normal state. We find that $T_c \approx 89.5$ K. A mu-metal shield around the cryostat reduced the ambient magnetic field below 10^{-6} tesla.

Figure 2 shows the spectral density of the flux noise, $S_\phi(f)$, at five temperatures. At 4.2 K, the noise is nearly white and is dominated by noise in the SQUID. At 77.4 K the spectral density of the low-frequency noise in the film has increased by a factor of about four compared with the 4.2-K value. The spectra at the three higher temperatures are $1/f$-like, with the noise increasing rapidly with temperature. We believe that the noise arises from the thermally activated hopping of flux quanta (or possibly bundles of quanta) among pinning sites in the film; this motion induces flux noise in the measuring SQUID. If we assume that we can characterize each hopping process by a single, temperature-dependent hopping time τ, the corresponding spectral density of the noise will be a lorentzian of the form $\tau/[1+(2\pi f\tau)^2]$. Provided that these processes are statistically independent and have a suitably broad distribution of characteristic times, their superposition yields a spectral density that scales as $1/f^\alpha$, where $\alpha \approx 1$ (ref. 11). The increase in the noise magnitude (Fig. 2) with temperature is qualitatively consistent with a thermal-activation model. We note also that the slope α varies with temperature, reflecting the fact that different hopping processes contribute to the noise as the temperature is changed.

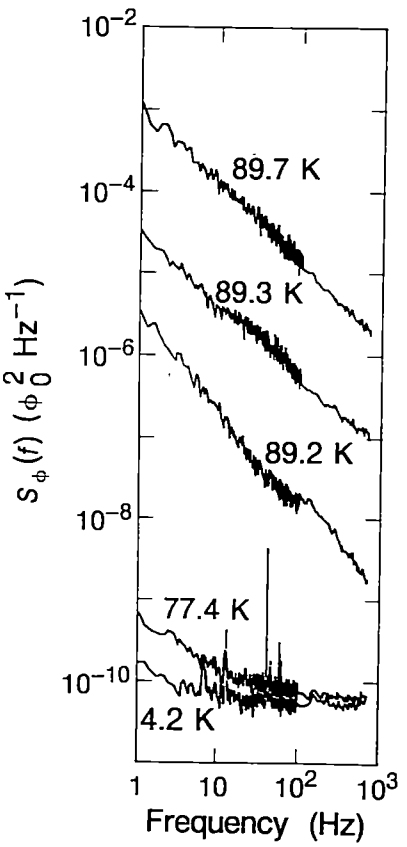

FIG. 2 Spectral density $S_\phi(f)$ of flux noise in a YBCO film at five temperatures. The spectral density detected by the d.c. SQUID has been multiplied by a factor of two to account for coupling losses between the film and the SQUID. At 4.2 K, the observed noise can be attributed to the SQUID measuring system; the SQUID contribution may be significant at temperatures up to 87 K. Spikes are from 60-Hz pick-up and microphonics.

In Fig. 3, we plot S_ϕ (1 Hz) against T. The noise rises slowly as temperature increases from 4.2 K to 87 K, and then rises steeply towards a very sharp peak at T_c. At 75 K, however, there is a small peak at 75 K that we have observed previously in another YBCO film[5], which we tentatively associate with a pinning mechanism, so far unidentified, with a particular value of pinning energy. To illustrate the behaviour near T_c, in Fig. 4 we plot B_0 and S_ϕ (1 Hz) on an expanded temperature scale. The noise peaks at the temperature where diamagnetic screening vanishes. The open circles indicate temperatures at which the noise was dominated by a single process in which a flux quantum switched back and forth between two states. This process was clearly visible in the time domain, and produced a lorentzian power spectrum. As the temperature was raised, the frequency of the switching event increased and its contribution to the noise at 1 Hz decreased in a manner consistent with thermal activation.

The inset of Fig. 3 shows the variation of $fS_\phi(f)$ with B, the perpendicular magnetic field in which the film was cooled. Although not apparent in this figure, the values of $fS_\phi(f)$ for zero applied field lie above the linear extrapolation to $B=0$. We expect the number of flux quanta in the film to be proportional to B, so that if they moved coherently the noise power should scale as B^2. On the other hand, if the vortices move incoherently, the noise power should be proportional simply to the number of vortices, that is, to B. The fact that $fS_\phi(f)$ is roughly linear in B for $B \leq 1.5$ mT implies that the interaction among the vortices producing the noise is negligible. Needless to say, there may be many vortices that actually interact strongly and as a result do not move or contribute to the noise. We note that at the highest applied field, 1.5 mT, the average vortex spacing of roughly 1 μm is greater than the vortex diameter of about one penetration depth[12] (~0.2 and 0.35 μm at 74 and 85 K, respectively), although in the presence of pinning the vortices need not be uniformly distributed.

Our upper bound on the spectral density of the flux noise of this *in situ* film between 70 and 80 K (Fig. 3), about 8×10^{-10} ϕ_0^2 Hz^{-1} at 1 Hz, is two orders of magnitude lower than that measured previously in our best post-annealed film[5]. There is no reason to believe that this value represents a minimum: further improvements in the quality of films may well yield even lower flux noise. This noise is low enough, however, to have significant implications for SQUID magnetometers. If we express the spectral density as a noise energy $\varepsilon(1\text{ Hz}) = S_\phi(1\text{ Hz})/2L$ for a SQUID with inductance $L = 100$ pH (for

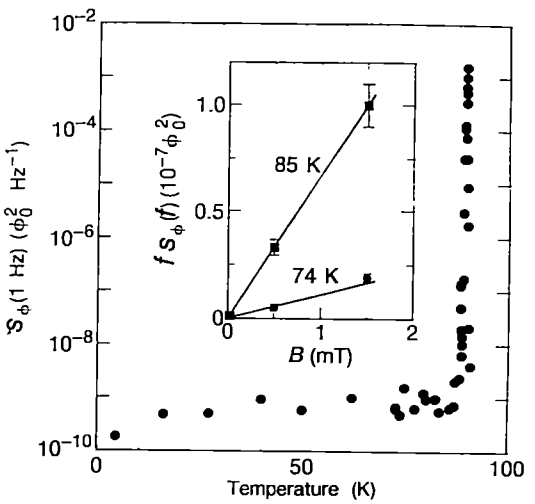

FIG. 3 Flux noise S_ϕ(1 Hz) against temperature for a YBCO film in zero applied field. Values below 8×10^{-10} ϕ_0^2 Hz^{-1} include significant contributions from the measuring system, and therefore represent upper limits on noise from the film. Inset shows $fS_\phi(f)$ (3 Hz $\leq f \leq$ 30 Hz) at two temperatures as a function of the perpendicular magnetic field B in which the film was cooled. Lines are guides to the eye.

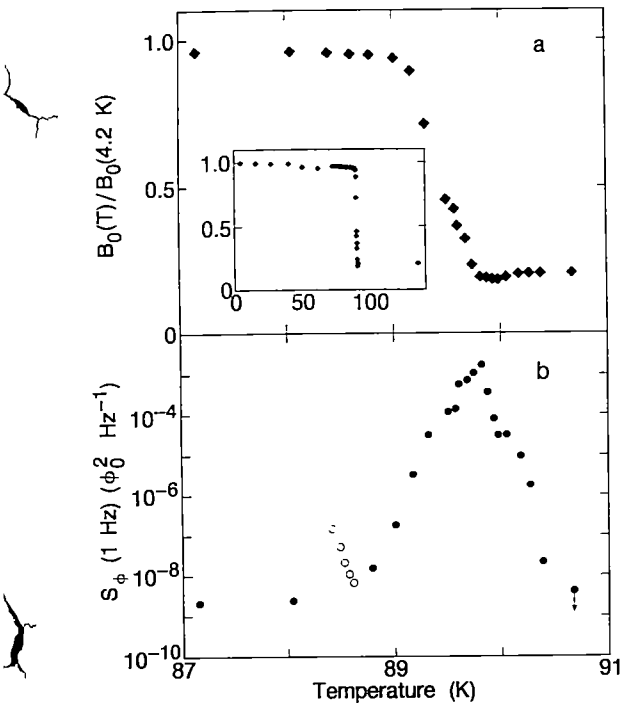

FIG. 4 *a*, Normalized applied magnetic field B_0 required to generate one flux quantum in the d.c. SQUID against temperature near T_c. The drop in B_0 reflects vanishing diamagnetic screening as the YBCO film becomes normal. Inset shows B_0 against T over the range 4.2–140 K. *b*, S_Φ(1 Hz) against T near T_c. Solid symbols: $1/f$ spectra; open symbols lorentzian spectra from bistable switching; downward arrow upper limit on noise.

example), we find $\varepsilon(1\ \text{Hz}) \approx 1.7 \times 10^{-29}\ \text{J Hz}^{-1}$. Compared with the noise energies of commercially available devices operated at 4.2 K, this value is only a factor of six greater than that of d.c. SQUIDs and a factor of two less than r.f. SQUIDs. At 10 Hz, the noise energy in our sample (including contributions from the measuring SQUID) is about $3 \times 10^{-30}\ \text{J Hz}^{-1}$, roughly 20 times less than the lowest value yet reported in a high-T_c SQUID of comparable inductance[4]. Of course, low flux noise is not in itself sufficient for low noise in a SQUID; one also has to make two junctions with sufficiently low white noise and $1/f$ noise. We note that one cannot make grain-boundary junctions in these high-quality films, and new technologies such as layered junctions (C. T. Rogers *et al.*, unpublished work) or edge junctions (R. H. Koch, Int. Conf. on Materials and Mechanisms of Superconductivity, Stanford, 1989) will be required. But it is most encouraging that a white-noise energy of $\sim 2 \times 10^{-30}\ \text{J Hz}^{-1}$ has already been reported in the quietest high-T_c d.c. SQUID produced so far[4]. Furthermore, if $1/f$ noise in the junctions arises from critical-current fluctuations, it can be reduced substantially by a double-modulation scheme[13,14]). Finally, our results also imply that flux transformers made from high-quality films should not induce significant levels of low-frequency noise into the SQUID. However, operation of either the SQUID or the flux transformer in modest ambient magnetic fields is likely to increase the level of low-frequency noise. □

Are classical weak-link models adequate to explain the current–voltage characteristics in bulk $YBa_2Cu_3O_7$?

THERE is now a consensus that in bulk high-temperature superconductors, it is the grain boundaries that limit the attainable critical current. Their behaviour resembles that of low-temperature superconductors containing 'weak links'[1,2] (regions of suppressed superconducting order). Here we report detailed measurements of the current–voltage characteristics of $YBa_2Cu_3O_7$, and find that the critical currents are too low, by two or three orders of magnitude, to be straightforwardly accommodated by classical weak-link models. This discrepancy is sufficiently fundamental to suggest that weak-link superconductivity in high-temperature superconductors has yet to be described adequately.

When the current through a weak link in a low-transition-temperature (low-T_c) superconductor greatly exceeds its critical current i_c, the slope dV/di of the current–voltage (I–V) characteristic is just the normal-state resistance r_n of the link. With some exceptions (to be discussed below), the zero-temperature critical current $i_c(0)$ is related to r_n by

$$r_n i_c(0) \sim \Delta(0)/e \qquad (1)$$

where $\Delta(0)$ is the zero-temperature superconducting energy gap, and e is the electronic charge. The behaviour of arrays of weak links depends greatly on their dimensionality; two-dimensional arrays fabricated from low-T_c materials have been studied extensively[3], but their critical currents are limited by the onset of the vortex-unbinding (Kosterlitz–Thouless[4]) transition, rather than by equation (1). Very little work has been done on three-dimensional arrays of these materials, for which vortex unbinding should not occur[5]; granular niobium composites[6], however, show behaviour that is consistent with equation (1) within an order of magnitude or so. In bulk sintered high-T_c superconductors, the granular weak-link network is certainly three-dimensional. We have examined the I–V characteristics of several bulk samples of high-quality $YBa_2Cu_3O_7$ at currents well above critical, using a sensitive pulsed-current system that eliminates the effects of joule heating[7].

Figure 1*a* shows typical I–V curves in zero applied field (the ambient magnetic field is about 50 μT); their linearity at high currents is immediately apparent. As the temperature is lowered, the critical current increases and at about 50 K it reaches the maximum available current of 10 A. Small magnetic fields depress the critical current sufficiently to allow the characteristics to be measured to lower temperatures (Fig. 1*b*) while altering the I–V slopes only slightly. In this range of field there is little difference between the effects of fields transverse and parallel to the current, and no irreversibility with respect to field cycling.

The data are summarized in Fig. 2, where the I–V-slope resistivities ρ', which we will relate to the weak-link resistance

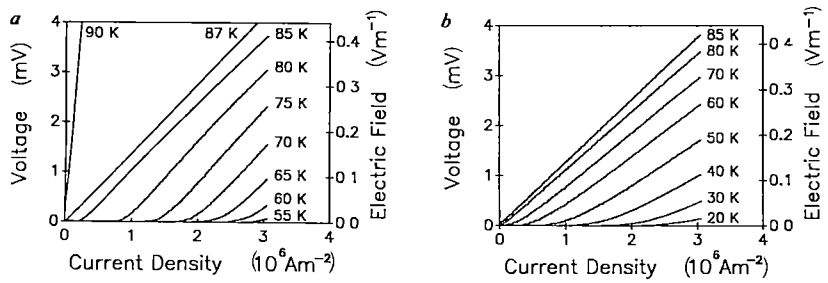

FIG 1 *I–V* characteristics of sample MS95/4 in *a*, the ambient field of 50 μT, and *b*, a transverse applied field of 2.3 mT. The linear regions reflect dissipation in the inter-granular weak links.

r_n, are plotted and compared with the resistive transition measured at low current (~1 mA). On cooling through the superconducting transition, ρ' first follows the low-current resistivity ρ extremely closely, but at the lower end of the transition it levels off to a small fraction of $\rho(100)$, the normal-state resistivity at 100 K.

Before discussing the significance of the magnitude of ρ', a number of other observations deserve comment. $YBa_2Cu_3O_7$ samples of lesser quality (data not shown), which consequently have much higher normal-state resistivities, behave in a qualitatively similar way except that at low temperatures ρ' levels off to a much larger fraction of $\rho(100)$, suggesting that the extra normal-state resistivity arises from weak links of greater resistance. Preliminary results on a $Bi_2Sr_2Ca_2Cu_3O_x$ sample resemble those of poor-quality $YBa_2Cu_3O_7$. Below T_c, ρ' depends only weakly on temperature and field (Fig. 2*b*), which will be discussed in detail elsewhere. Qualitatively, the maximum in ρ' at ~73 K that occurs in zero applied field can be understood in terms of the current distribution over the sample cross-section: immediately below T_c, the penetration depth λ_{net} of the granular network[8] is large compared with the sample diameter, so that the current is distributed uniformly and ρ' represents simply the macroscopic series–parallel combination of weak-link resistances. As the temperature is lowered, λ_{net} diminishes, the current is carried non-uniformly and the macroscopic resistance increases. A small field not only depresses the critical current density J_c but also increases λ_{net} and so restores uniformity to the current distribution, thereby decreasing ρ' in this temperature range. The decrease of ρ' in zero applied field at lower temperatures reflects the intrinsic temperature variation of the weak-link resistance r_n, and indicates that the weak links are metallic rather than semiconducting.

Returning now to the central question of the magnitude of ρ', we model the material as a network of identical weak links, each having normal-state resistance r_n and critical current i_c, forming a cubic array of cell size d (a typical grain size); we make no other assumptions about the geometry. Clearly, $r_n = \rho'/d$ and $J_c = i_c/d^2$. The grain size is ~10 μm, so that, just below T_c, $r_n \approx 20$ μΩ. We estimate[6] $J_c(0) \approx 10^7$ A m^{-2}, so that $i_c(0) \approx 1$ mA. Consequently, the product $r_n i_c(0)$ is not more than 20 μV; a $YBa_2Cu_3O_7$ sample of somewhat smaller grain size (data not shown) had larger ρ' and J_c, again leading to estimates of $r_n i_c(0)$ of about 20 μV. Self-field effects may have led us to somewhat underestimate J_c; on the other hand, we have used the value of r_n obtained just below T_c, and it decreases with temperature. We can be confident that the low-temperature limit of $r_n i_c(0)$ is not greater than 100 μV. By contrast, the T_c of 92K suggests that the energy gap in $YBa_2Cu_3O_7$ is ~20 meV, so that there is a discrepancy of two to three orders of magnitude with equation (1). In experiments[9] on bi-crystals that share a common *c*-axis (and thus for which current flows in the favourable *a–b* plane), the grain boundary weak links were found to have $r_n i_c(0)$ values in the range 0.3 to 3 mV.

There are two important situations in which $r_n i_c(0)$ for a microscopically uniform weak link can be much less than $\Delta(0)/e$, namely for a superconductor–normal–superconductor (proximity-effect) junction with a normal region many coherence lengths thick, and for a wide junction. In the former case, it is well-known that J_c depends exponentially on temperature[4,10], in clear contrast to the much weaker dependence that is observed in the new materials[6,8]. For a junction whose width w is large compared with the Josephson penetration depth λ_J, the average critical current density j_{av} is $\sim(2\lambda_J/w)j_c$, where j_c is the critical current density of a narrow junction. λ_J is given by[11] $\lambda_J^2 = \Phi_0/(4\pi\mu_0 \lambda j_c)$, where λ is the usual penetration depth. j_c can be eliminated, and the product $(\lambda_J w)$ estimated from the measured (average) critical current density J_c and λ (~0.3 μm). We find $(\lambda_J w) \approx$ 100 μm^2. Because w cannot exceed the grain size (~10 μm), λ_J cannot be less than w, and so we can discard the possibility that the junctions are wide. We may note also that if an additional intergranular flux flow term is contributing to our inferred value of r_n, the discrepancy with equation (1) becomes even worse.

Thus, either the theory of classical weak links is inapplicable to grain boundaries in high-T_c superconductors (which, given the extreme shortness of the coherence length ξ, needs to be considered), or the supercurrent transport across grain boundaries is microscopically inhomogeneous, as has been suggested by Larbalestier and co-workers on the basis of microstructural studies and the temperature dependence of the critical current[12,13]. For example, it might be that, at any one grain boundary, supercurrent flows across only a much smaller fraction of the interface area than does normal current; the resistance of the latter would shunt that of the former and thereby reduce the observed values of r_n and $r_n i_c(0)$. Alternatively, the disproportionation between super- and normal currents could occur between different orientations of grain boundaries. In either case, equation (1) would no longer apply. The breakdown of equation (1) in the high-T_c materials is of considerable fundamental significance. In low-T_c superconductors, the relationship is so general because it reflects the equality of the matrix elements that control the transmission of pairs (in the superconducting state) and of electrons (in the normal state) across the weak

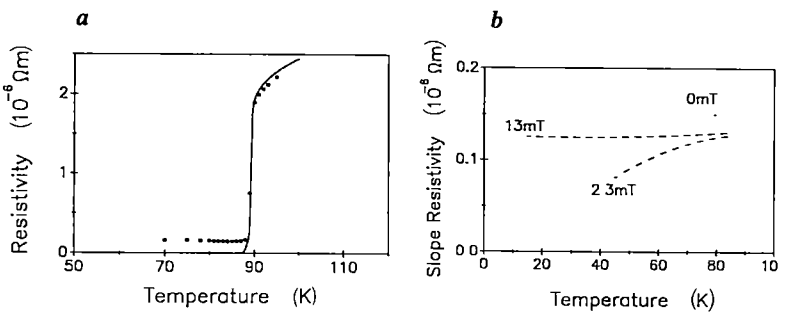

FIG. 2 *a*, Circles, high-current slope resistivities ρ' derived from *I–V* characteristics, as in Fig. 1; solid line, low-current resistivity ρ. *b*, ρ' on an expanded scale, showing the weak dependence on temperature below T_c and the effect of small applied fields.

link; it depends upon neither the superconducting mechanism nor the details of the weak link. The low critical currents across grain boundaries in high-T_c superconductors suggest that the situation is more complicated than that in the low-T_c materials. □

ISOTOPIC enrichment of organic compounds in the stable minor isotopes ^{15}N, ^{17}O and ^{18}O, which are often used as tracers, is commonly achieved by syntheses that involve isotopically enriched simple precursors such as NH_3, H_2O and CO_2. But such labelled compounds are not always commercially available or readily synthesized. Here we report the direct enrichment of nitrogen and oxygen isotopes in dissociable compounds such as amines, phenols and carboxylic acids, using a high-performance liquid-chromatography technique. The separation method relies on the isotope effects on the dissociation equilibria of weak acids and bases that occur in protonation or deprotonation of the relevant isotopes. Enrichment of ^{15}N to 5–10% isotopic purity in *N,N*-dimethylaniline was achieved from the natural abundance of 0.37% in less than 14 hours; subsequent runs brought the isotopic purity to 90% or more. Enrichment of ^{17}O and ^{18}O to similar high purities in *p*-nitrophenol was also obtained. Thus, where suitable dissociation eqilibria exist, direct isotopic enrichment is possible using standard techniques without the need to devise complex synthetic pathways.

In addition to the conventional isotope separation methods including chemical exchange, distillation and ion-exchange chromatography, laser-based methods have been intensively studied recently. With the exception of ion-exchange chromatography[1–6], these methods require special equipment for the isotopic enrichment of simple working substances, and the desired labelled compounds must be synthesized after enrichment. The advantages of the ionization-control method over the conventional ion-exchange chromatography[1–6] include the availability of high-performance columns and the applicability for a wide range of compounds.

In reversed-phase liquid chromatography of ionizable compounds, the neutral form of the compound is retained much longer by the hydrophobic stationary phase than is the ionized form[7], which is much more hydrophilic. Accordingly an acid is retained much longer at lower pH, whereas an amine shows the opposite tendency. Figure 1 shows that the apparent pK_a values are 4.6 for *N,N*-dimethylaniline (DMA) and 7.1 for *p*-nitrophenol (PNP).

For the dissociation equilibria of an acid AH,

$$AH + H_2O \overset{K_a}{\rightleftharpoons} A^- + H_3O^+$$

the chromatographic retention or capacity factor k' is[7]

$$k' = \frac{k'_{AH}[AH]}{[AH]+[A^-]} + \frac{k'_{A^-}[A^-]}{[AH]+[A^-]} = \frac{k'_{AH}}{1+K_a/[H_3O^+]} + \frac{k'_{A^-}-K_a/[H_3O^+]}{1+K_a/[H_3O^+]} \quad (1)$$

where k'_{AH} and k'_{A^-} are the retentions of the neutral and dissociated forms of the acid. Similarly, for the dissociation equilibrium of an amine B,

$$BH^+ + H_2O \overset{K_a}{\rightleftharpoons} B + H_3O^+$$

the chromatographic retention is

$$k' = \frac{k'_{BH^+}[BH^+]}{[BH^+]+[B]} + \frac{k'_{B}[B]}{[BH^+]+[B]} = \frac{k'_{BH^+}}{1+K_a/[H_3O^+]} + \frac{k'_{B}K_a/[H_3O^+]}{1+K_a/[H_3O^+]} \quad (2)$$

where k'_B and k'_{BH^+} are the retentions of the neutral and protonated forms of the amine. The extent of ionization determines the retention of the ionizable species at particular pH in the ionization-control mode of reversed-phase liquid chromatography.

As the dissociation of a proton bound to a heavier isotope is slightly less favourable than that of a proton bound to a lighter isotope, the dissociation constant K_a is smaller for species with

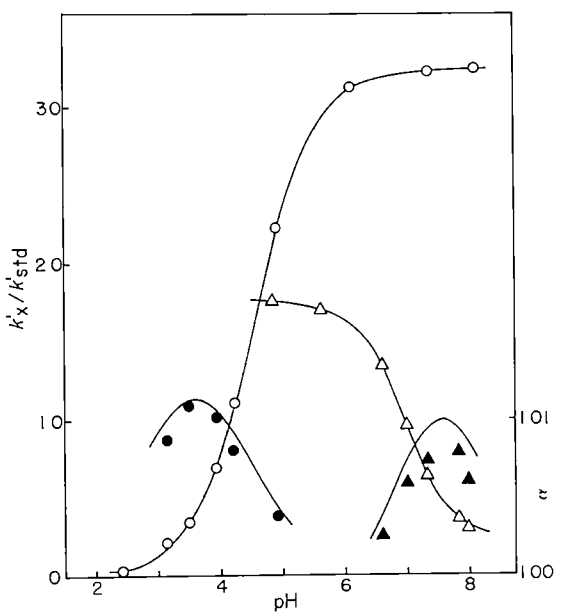

FIG. 1 pH dependence of k' values of DMA-^{14}N (○) and PNP-^{16}OH (△), and the pH dependence of isotopic separation factors α between DMA-^{14}N and DMA-^{15}N (●) and between PNP-^{16}OH and PNP-^{18}OH (▲) The k' values of DMA and PNP were normalized by using the k' values of 3-phenylpropanol and benzyl alcohol, respectively[13] Curves were drawn based on the results obtained with the individual isotopic compounds. Column Cosmosil-5C_{18}, 5-μm particles (Nacalai-Tesque), 4 6-mm inner diameter, 30 cm (15 cm × 2) Mobile phase buffer–acetonitrile (80%–20% (v/v)) with 0 01% triethylamine for DMA, and buffer–methanol (95%–5% (v/v)) for PNP Temperature 30 °C

a heavier isotope[8,9]. This isotope effect leads to the difference in the extent of ionization of the species depending on the isotope mass, which in turn leads to a difference in the chromatographic retention of the isotopic compounds at a pH near the pK_a where both two terms of the righthand side of equations 1 and 2 make significant contributions.

Figure 2*a* shows the separation of a standard mixture (1:1) of DMA-^{14}N and DMA-^{15}N at pH 3.8. We found the nitrogen isotope effects on the dissociation of protonated amines, $^{14}K_a/^{15}K_a$, to be 1.019 for aniline[10] and 1.014 for DMA, in agreement with the reported values[11,12]. A maximum chromatographic separation factor, $^{14}k'/^{15}k'$, of 1.011 was observed at pH 3.5–4.0 for the isotopic DMA.

To enrich ^{15}N from the natural abundance of 0.37%, we collected ~5% of the total peak, including the fraction corresponding to DMA-^{15}N, as shown in Fig. 2*b*. The rechromatography of the collected fraction in Fig. 2*c* shows that the isotopic purity of ^{15}N, by the comparison with the standard chromatograms, is ~6%, which agrees well with the results of gas chromatography/mass spectrometry determination. We can obtain an isotopic purity as high as 90% by collecting an appropriate fraction of the chromatographic separation shown in Fig. 2*c*.

The separation of ^{16}O and ^{18}O requires a similar column efficiency as that required for the separation of ^{14}N and ^{15}N. We have found the oxygen isotope effects on the dissociation $^{16}K_a/^{18}K_a$ to be 1.020 for benzoic acid (BA)-$^{16}O_2$ and BA-$^{18}O_2$ (ref. 13), and 1.017 for PNP-^{16}OH and PNP-^{18}OH. This results in an isotope separation factor $^{18}k'/^{16}k'$ of 1.010 for PNP. About 800,000 theoretical plates are required to achieve complete resolution of PNP-^{16}OH, PNP-^{17}OH and PNP-^{18}OH, which can be provided by a column system of 15–20 m. We show the separation of the three oxygen isotopes by recycle chromatography[13,14] of PNP in Fig. 3. The results show that ^{17}O, which is currently available at less than 60% isotopic purity in the form of H_2O, can be enriched to a very high isotopic purity (90% and above) by simple fractionation of the chromatographic effluent. The enrichment of ^{18}O will be considerably easier than that of ^{17}O because of its greater natural abundance.

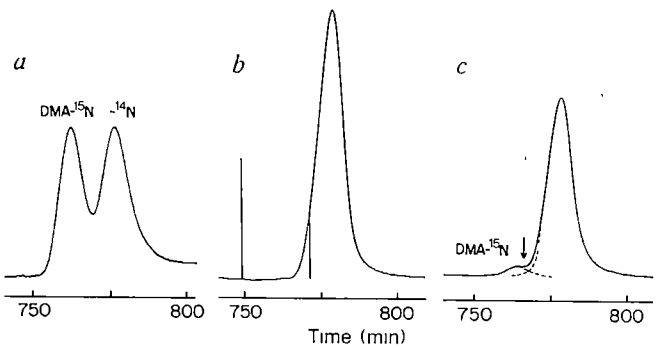

FIG 2 Separation of DMA-^{14}N and DMA-^{15}N *a*, 1 1 mixture of DMA-^{14}N and DMA-^{15}N *b*, Fractionation of DMA-^{15}N from ordinary DMA. Every 40 min we injected 0 1 mg of ordinary DMA dissolved in 10 μl of the mobile phase (The sample size and separation time depend on the column size and flow rate) We collected the fraction between the two spikes, containing ~5 μg of DMA, each time We removed buffering species by chromatography of the combined collected fractions on a C_{18} column using 60% methanol. Following the evaporation of methanol, we extracted the enriched material with ether The gas chromatography/mass spectrometry analysis of the extracted DMA gave relative intensity, 100.00 80 75.11.11 for *m/z* values 120, 121 and 122 (M−1, M$^+$, M+1), respectively, compared with 100 00·72 31.5 77 for ordinary DMA, indicating ~6 5% isotopic purity of ^{15}N *c*, Rechromatography of the separation products from *b*. Dashed lines indicate the simulated traces for DMA-^{15}N and DMA-^{14}N at a 6 94 ratio We expect a 90% isotopic purity for DMA-^{15}N, when the fraction is collected before the time marked by the arrow[15]. Column. Capcellpak C_{18}-SG, 5-μm particles (Shiseido), 4 6-mm ID, 350 cm (10×15 cm + 8×25 cm) Mobile phase. 0 5M acetate buffer–acetonitrile (90%–10% (v/v)) with 0 01% triethylamine at pH 3 8 Flow rate 0 37 ml min^{-1} Temperature 50 °C

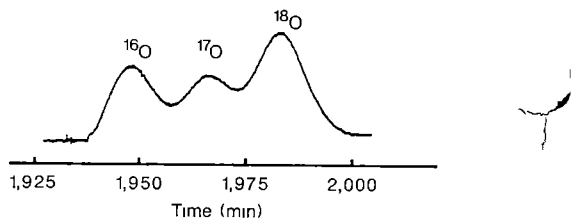

FIG. 3 Separation of PNP-^{16}OH, PNP-^{17}OH and PNP-^{18}O The solutes were recycled 12 times through a pair of 45-cm column systems by using an automated column-switching valve[13,14] Increases in the peak width and separation factor were observed because of the effect of the pressure gradient in the column[16] We expect about 90% isotopic purity for PNP-^{17}OH, if the fraction between the two minima were to be collected[15] Column Cosmosil-5C_{18}, 4.6-mm ID, 90 cm (6×15 cm) Mobile phase 0 02M-phosphate buffer-methanol (95%–5% (v/v)) with 0 001M sodium octanoate at pH 7.6 Flow rate· 0 4 ml min^{-1} Temperature 40 °C A mixture of ~0 5 μg each of PNP-^{16}OH, PNP-^{17}OH and PNP-^{18}OH was injected

In spite of the small isotope separation factors, the use of high-performance columns and optimized mobile phases has enabled us to achieve a fast separation of oxygen and nitrogen isotopes by reversed-phase liquid chromatography. By carrying out reversed-phase liquid chromatography at a pH value 0.5–1.0 pH units higher than the pK_a for weak acids or 0.5–1.0 pH units lower than the pK_a for weak bases, one can obtain enrichment of the ^{15}N, ^{17}O or ^{18}O atoms involved in the dissociation equilibria. Current polymer-based packing materials allow operation of the chromatographic process in the range pH 2–12. □

Biases in satellite-derived sea-surface-temperature data

Richard W. Reynolds*, Chris K. Folland† & David E. Parker†

STRONG[1] indicates from satellite data that global sea surface temperature increased by 0.1 °C per year over the 6.5-year period between January 1982 and June 1988. Here we show that no significant trend can be seen in three analyses of global sea surface temperatures that are based on *in situ* data in this limited period, nor in an independent analysis of sea-surface-temperature (SST) and land-air-temperature data. Satellite data are blended and adjusted in one of the above SST analyses. An unadjusted satellite

SST analysis similar to that used by Strong shows the same, but probably spurious, trend.

Three of the SST analyses we use here were produced at the Climate Analysis Center (CAC) of the US National Meteorological Center, and comprise an *in situ*, a satellite and a blended analysis. The *in situ* SST analysis uses radio-transmitted data from ships and buoys. The satellite analysis uses the multichannel SST (MCSST) data reported by Strong, but with small differences in analytical procedure. The blended SST analysis combines satellite and *in situ* SST observations by using the *in situ* analysis to define 'ground truth' temperatures in regions of sufficient *in situ* data and the analysed satellite data to define the shape of the SST field where there are few or no *in situ* data[2]. Where enough *in situ* observations are available, they provide all the information about SST; elsewhere the adjusted satellite field provides increasing information about SST patterns as *in situ* data become sparser.

We also use a quality-controlled *in situ* SST analysis (produced by the UK Meteorological Office (UKMO)[3,4], as well as a data set of air temperatures measured at night (UKMO). Both data sets use temperatures measured by ships and buoys. We excluded daytime air-temperature measurements because of the risk that variable biases could be introduced by overheating of the ship's thermometer housing by day[5]. In the regional time series, the grid-box data are weighted by the cosine of the latitude.

Figures 1*a* and 1*b* show monthly anomalies for the CAC SST analyses for January 1982–March 1989, averaged over two regions: Equator to 60° N (the same as Strong's Northern Hemisphere area), and 40° S to the Equator. The anomalies were calculated relative to a 1950–79 climatology. The southern limit of 40° S was selected for the second region because of the scarcity of *in situ* observations south of 40° S. The Northern Hemisphere satellite time series (light line) in Fig. 1*a* is similar to that shown by Strong (his Fig. 1*b*); the two series have the same linear trend of 0.16 °C yr^{-1} between January 1982 and June 1988. The two satellite time series are not quite identical because CAC and Strong used different climatologies and averaged the MCSST data on different grids (2° and 2.5°, respectively). In addition, Strong averaged only grid values with data (that is, he did not interpolate data for grids where the satellite data were unavailable because of cloud cover) and did not use cosine weighting to reduce the weight of boxes at higher latitudes. He effectively assumed that all latitude zones over the ocean had the same longitudinal extent because he averaged zonal means of SST with equal weight for each zone (Strong, personal communication). The CAC technique interpolated data for missing grid points over the ocean and used all oceanic grid points (within the given latitudinal bounds) with cosine weighting. Although these analysis differences cause small monthly changes, major features, such as the above trends, were unaffected. (We note that the confidence limits quoted by Strong for his linear trends are too narrow as he did not account for the persistence of SST anomalies for periods longer than a month.)

Figure 1*a* also shows the CAC blended (thick line) and CAC *in situ* SST analyses (dots) for 0° to 60° N; the two data sets are nearly identical (correlation $r = 0.97$ for January 1982–March 1989). There is no significant trend in either set for January 1982–June 1988 or January 1982–March 1989. This agreement between *in situ* and blended SST anomalies demonstrates that the blending technique successfully adjusts the satellite data relative to the *in situ* analysis. The warmth of 1982–83 is mostly due to the 1982–83 El Niño. The uncorrected satellite data, however, indicate very low SSTs during this period (see ref. 6, comment on the same paper).

Figure 1*b*, for the Equator to 40 °S, covers a smaller area than Strong's Fig. 1*c* (Equator to 60° S) but the trend of 0.12 °C yr^{-1} in the CAC satellite data for January 1982–June 1988 is similar to Strong's value of 0.10 °C yr^{-1} over his larger area. *In situ* data

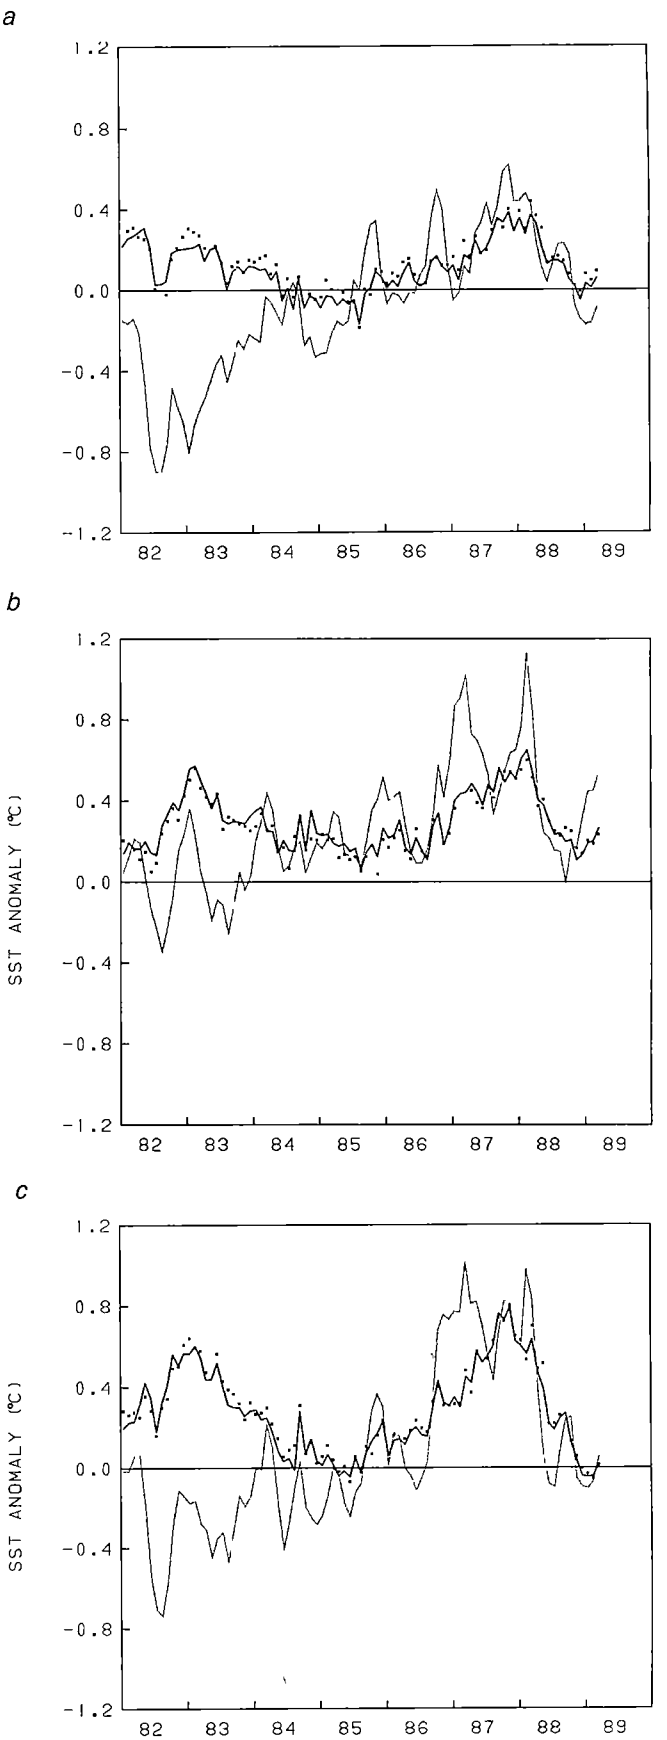

FIG 1 *a*, Time series of CAC SST anomalies for the Northern Hemisphere between 0° and 60° N, January 1982–March 1989. Satellite anomalies are indicated by a light line, blended anomalies are indicated by a heavy line; *in situ* anomalies are dotted. *b*, As in *a*, except the region is 40° S to 0°. *c*, As in *a*, but for the region 20° S to 20° N.

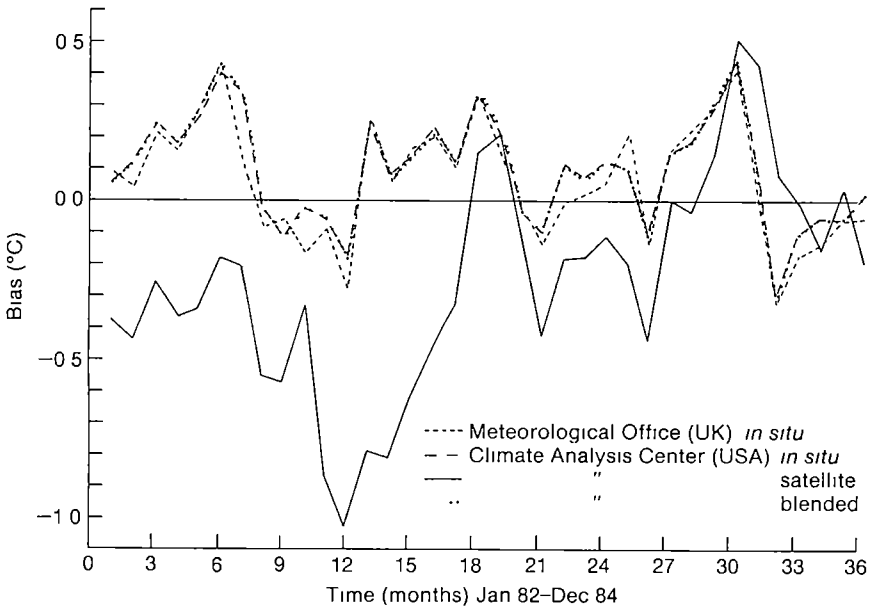

FIG 2 Mean differences between UKMO *in situ*, CAC satellite, CAC *in situ* and blended analyses and quality-controlled expendable bathythermograph data for the region 0° to 60° N for January 1982–December 1984

again show no significant trend Agreement between the CAC blended and *in situ* analyses is again very good ($r = 0.96$ for January 1982–March 1989).

Strong states that the warming trend in the satellite data is about twice that of a warming trend shown by *in situ* data sources. The Oort *et al.*[7] data that he discusses in this connection extend only to 1985, for the period of overlap with Strong's record, Oort *et al.* use the CAC blended analysis (Figs. 1*a* and 1*b*), which, of course, includes adjusted satellite data. No significant global or hemispheric warming trend exists in the limited period of overlap with Strong's data (1982–1985). A linear trend fitted to the Oort *et al.* Northern Hemisphere data over this four-year period shows slight cooling.

To help clarify the relative accuracies of satellite and *in situ* SST data, we have compared them with expendable bathythermograph (XBT) data for January 1982–December 1984. Although the SSTs from XBTs are sparser than the conventional surface marine *in situ* observations used above (the ratio of number of XBTs to conventional SSTs is roughly 5%), they are useful because XBTs are not included in any of the analyses used here and are widely distributed spatially. Figure 2 shows time series of CAC satellite, CAC *in situ*, CAC blended and UKMO *in situ* SST analyses for the Northern Hemisphere subtracted from quality-controlled near-surface SST data derived from XBTs. We call these differences 'biases'. Mean biases were 0.04 °C, 0.04 °C and 0.01 °C for CAC *in situ*, CAC blended and UKMO analyses respectively, and were not statistically significant. The mean bias for the satellite analysis was −0.30 °C and was highly significant, showing that the satellite-derived temperatures were almost certainly too low overall. Furthermore, the satellite bias varied from near −0.8 °C between mid-1982 and early 1983 to small values towards the end of 1984. Thus the satellite biases varied in such a way as to give rise to a pronounced spurious warming trend in 1982–84. In contrast, the XBT data support the lack of trend in the other SST analyses.

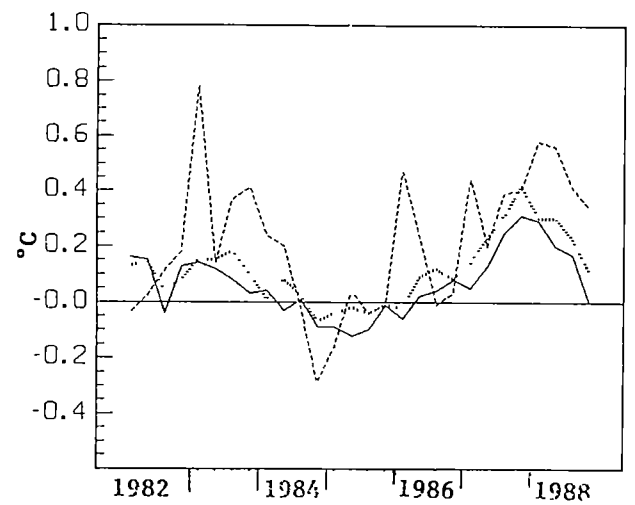

FIG 3 Seasonal anomalies for the Northern Hemisphere referred to a 1951–80 climatology for January–March 1982 to October–December 1988 Solid line, UKMO sea surface temperature, dotted line, UKMO night marine air temperature; dashed line, land air temperature[8,9]

During the period of interest, two El Niño/Southern Oscillation events (1982–83 and 1986–87) caused strong warming of the tropical oceans, primarily in the central and east Pacific. Figure 1*c* shows time series of the monthly CAC satellite, *in situ* and blended analyses between 20° S and 20° N. These tropical warmings are shown in the *in situ* and blended analyses. As discussed by Robock[6], El Chichón aerosols resulted in a negative bias in satellite SST retrievals from April 1982 to the end of 1983. Thus, the satellite analysis in Fig. 3 does not show the large-scale warming associated with the 1982–83 El Niño event. Despite this, closer analysis shows that the satellite retrievals did detect a locally strong but distorted El Niño warming. The warming observed in the satellite data (south of 5° N in the tropical east and central Pacific) was offset, however, not only by unrealistic negative biases north of this latitude in the Pacific but also by widespread biases in the other tropical oceans.

Further support for the view that the warming trend in the satellite data is mostly false comes from Fig. 3. It shows, for January 1982–December 1988 and the Northern Hemisphere, seasonally averaged (1) UKMO SST anomalies, (2) UKMO night marine-air-temperature (NMAT) anomalies and (3) air-temperature anomalies on land[8,9] These data are all referred to a 1951–80 average. The correlation between seasonal SST and NMAT data sets over this period is very high ($r = 0.92$); that between the land air and ocean is less, as the land data show more interseasonal variability ($r = 0.54$ with SST and $r = 0.62$ with NMAT). Nevertheless, neither the land nor the marine data show any significant trend over the period 1982–88. Indeed, two El Niño/Southern Oscillation events dominated the record so completely that calculation of a trend over this period is almost meaningless.

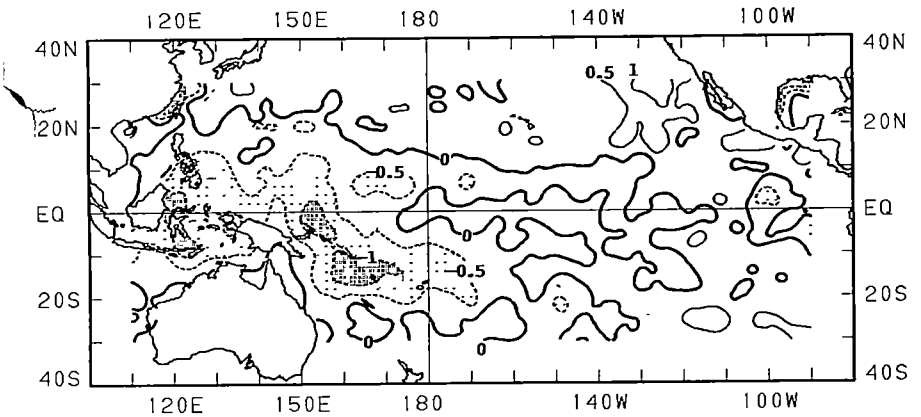

FIG. 4 Mean difference between daytime and night-time satellite SST values over the tropical Pacific for February 1989. The contour interval is 0.5 °C; solid contours indicate positive differences and dashed lines negative differences. The heavy solid line is the zero-difference contour. Dotted regions indicate differences between −0.5° C and −1 °C. Stippled regions indicate differences more negative than −1 °C.

We are much less certain about the adequacy of *in situ* data for the Southern Hemisphere because of its poor coverage. Southern Hemisphere satellite data may not always be completely adequate, however, even after all possible influence from El Chichón ceased. In Fig. 4 we show satellite day-minus-night differences for February 1989, a more recent period than that covered by Strong. In the western tropical Pacific, there is a large region where daytime satellite SSTs are more than 0.5 °C colder than corresponding night-time values. This pattern had persisted since the new NOAA-11 satellite became operational in November 1988, but tropical daytime SSTs could not be colder than night-time SSTs for such a long period. Comparisons of satellite retrievals with drifting-buoy SST measurements in this region since November 1988 confirm that daytime satellite temperatures are lower than the buoy temperatures. Such problems must be corrected before satellite data can be used on their own to estimate climate trends.

Accurate global SST data from satellites are urgently needed, especially in the Southern Hemisphere, to help provide trustworthy analyses of the expected future global surface warming. For the recent past, the best outcome would be that satellite SST data available since the 1970s could be corrected (retrospectively) for their biases, blended with (corrected) *in situ* SST data and combined with surface-land and sea-ice analyses. □

Beryllium in marine pore waters: geochemical and geochronological implications

D. L. Bourlès*, G. Klinkhammer, A. C. Campbell, C. I. Measures, E. T. Brown & J. M. Edmond

Department of Earth, Atmospheric and Planetary Sciences, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

DIAGENETIC remobilization and hydrothermal inputs have been invoked as possible explanations for the discrepancy between the theoretical and measured temporal decrease of the non-detrital $^{10}Be/^{9}Be$ ratio observed in sediments[1]. Remobilization is also consistent with water-column profiles of beryllium, which indicate a significant benthic flux from sediments[2]. To evaluate the impact of diagenetic recycling on the beryllium isotopic composition of marine waters and the effects of this process on the beryllium geochronometer, we have analysed the ^{9}Be content of interstitial waters from different environments. Here we report the first pore-water profiles for ^{9}Be in oxic and suboxic pore waters as well as some preliminary results from hydrothermal sediments collected in the Guaymas Basin. Our results suggest that the use of the beryllium isotopes as a geochronometer is not affected either by sedimentary diagenesis at oxic and suboxic sites or by input of hydrothermally derived ^{9}Be more than a few kilometres from vent sites.

* Present address: Centre de Spectrometrie Nucleaire et de Spectrometrie de Masse, Batiment 108, 91405 Campus Orsay, France.

Oxic pore waters were collected at MANOP site S in the central equatorial Pacific; suboxic pore-water samples were collected at the Patton Escarpment (Southern California Borderland)[3]. Subcores taken with plastic core liners from box cores were sectioned and centrifuged at *in situ* temperatures and, at the suboxic site, under nitrogen. Pore water thus obtained was immediately filtered and acidified.

Interstitial waters from Guaymas Basin were obtained during dives of the submersible *Alvin* in January 1982. Core 1172 is from the Southern Vent Field immediately adjacent to an active 20-m-high hydrothermal mound, and core 1174 was taken in the vicinity of East Hill near hydrothermal deposits[4]. They were obtained with plastic *Alvin* core tubes. The sediment was extruded, sectioned and squeezed in an acid-cleaned plastic pore-water press. The fluids were immediately filtered and sealed in glass ampoules.

Beryllium analyses were made by gas chromatography with electron-capture detection of its 1,1,1-trifluoro-2,4-pentanedione derivative. The details of the method have been presented in ref. 5. Aliquots ranging from 10 to 30 ml were required for these analyses.

Beryllium concentration–depth profiles for the oxic and suboxic sites are presented in Fig. 1 along with interstitial Mn and Si data. The beryllium concentrations near the interface are a factor of 2.5 (MANOP site S) and 3.3 (Patton Escarpment) higher than the average North Pacific bottom water (29.4± 1.7 pM, refs 2 and 7). This, coupled with the observed increase in concentration with depth, implies a flux of beryllium out of the sediments.

We estimated steady-state fluxes to bottom waters for each location assuming molecular Fick's-law diffusion and a linear concentration gradient across the interface. We estimated an effective bulk sediment diffusion coefficient of 1.7×10^{-6} cm^2 s^{-1}

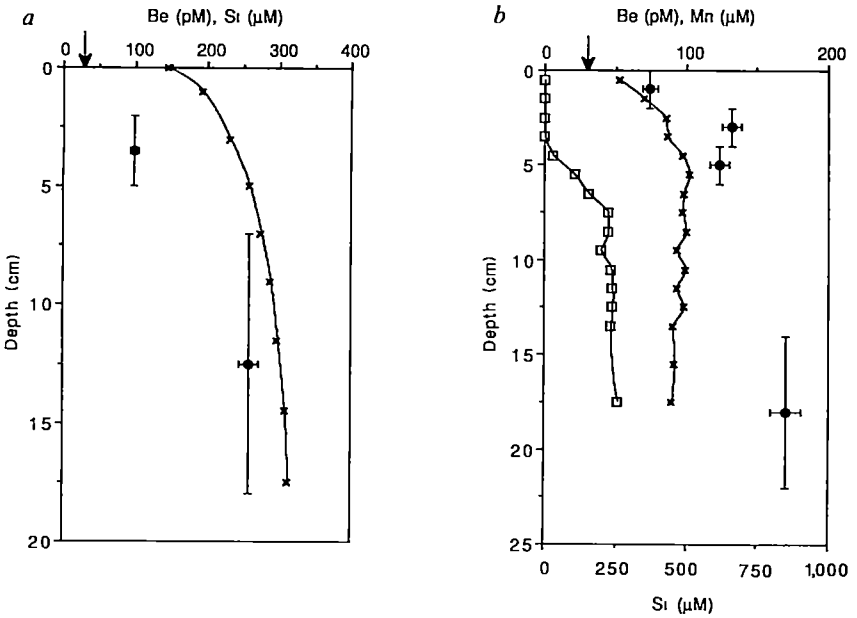

FIG. 1 Pore-water ^{9}Be (filled circles), Mn (open squares) and Si (crosses) as a function of depth. *a*, MANOP site S (oxic environment). This site, selected to represent typical provinces of siliceous sedimentation, is located at 11° N, 140° W with a water depth of 4,910 m. Oxygen was present throughout the core and no appreciable dissolved Mn was detected. *b*, Patton Escarpment site BC-10 (suboxic environment). This site is located at 32.5° N, 120° W with a water depth of 3,800 m. Mn and Si data are from a nearby core, PSC-10 (ref. 6). The arrows indicate Be bottom-water value.

by applying the Stokes–Einstein correction for temperature to the value calculated[8] for Be^{2+} and using a porosity of 90%[3,9] and an estimated tortuosity factor of 0.7. The concentration gradients are 18.5 ± 0.7 pM cm^{-1} at MANOP site S and 35.1 ± 6.3 pM cm^{-1} at Patton Escarpment, which yield lower limits for total flux of 1.0 pmol cm^{-2} yr^{-1} (Site S) and 1.9 pmol cm^{-2} yr^{-1} (Patton). Within reasonable uncertainties, these fluxes are consistent with the estimate[2] derived from the distribution of beryllium in the water column of the central North Pacific (1.5 pmol cm^{-2} yr^{-1}). These values are negligible compared with the non-detrital Be flux to the sediments.

At MANOP Site S and Patton Escarpment the correlation coefficients between pore-water Be and pore-water Si ($r = 0.998$ and 0.905 respectively, Fig. 1) suggest that the Be released to pore water is associated with the silica being dissolved in these sediments. At MANOP site S, the Be/Si mole ratio in the pore water calculated from the concentration gradients of both elements in the upper 3.5 cm is 715×10^{-9}. Averaging the Si concentrations over the depth interval 7–18 cm, we calculate a Be/Si ratio of 782×10^{-9}. At Patton Escarpment, the Be/Si ratios estimated the same way are 398×10^{-9} and 376×10^{-9} in the upper 3 cm and at 14–22 cm respectively. These values are consistent with a biogenic opaline source for Be, given the uncertainties in the Be/Si ratio of amorphous biogenic silica (Table 1). They indicate that the depth–concentration profiles of both elements are linked to the solubility of amorphous silica[13] which may be controlled by clay mineral-aqueous silica equilibria[15].

We note that the highest levels of ^{9}Be in pore water measured in this study (258 pM) represents less than 0.02% of the beryllium present in the non-detrital phase of the associated sediments[1]. As the $^{10}Be/^{9}Be$ ratio in opal is also nearly equal to that in the hydroxylamine-leachable phase[1] of the sediments, it seems that remobilization of beryllium isotopes during sedimentary diagenesis does not affect the $^{10}Be/^{9}Be$ ratio of the non-detrital phase and therefore does not affect the use of Be isotopes as a geochronometer.

The pore-water data from the Guaymas Basin are presented in Fig. 2 with the associated dissolved-Mn profile. Not only are the shapes of the profiles different from those observed in pelagic and hemipelagic pore waters but the concentrations are also one to two orders of magnitude higher and show more variability. In fact, the ^{9}Be concentration measured near the sediment–water interface in core 1172-2 is at the low end of the range for Be in hydrothermal fluids[15,16].

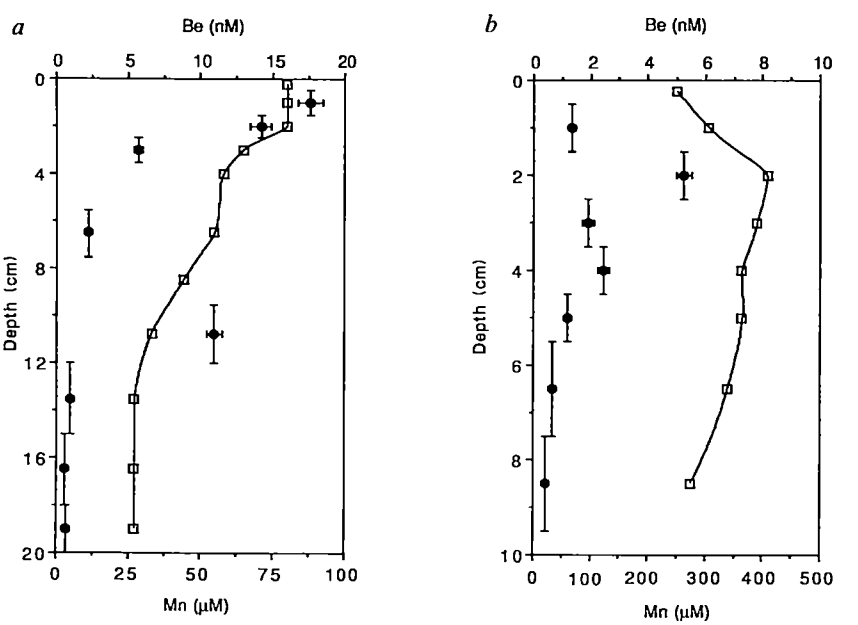

FIG. 2 Pore-water ^{9}Be (filled circles) and Mn (open squares) as function of depth. *a*, Core 1172-2. *b*, Core 1174-3. Core 1174-3 had not undergone any hydrothermal alteration, whereas core 1172-2 showed signs of previous hydrothermal alteration in the solids, but the interstitial waters indicated that no advection of hydrothermal fluids was occurring when it was collected[4].

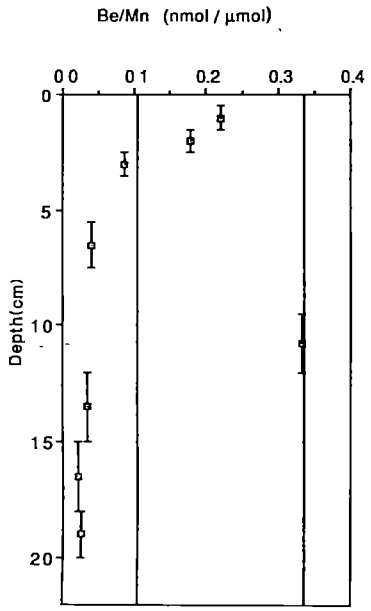

FIG. 3 Pore-water Be/Mn ratios from Guaymas Basin as a function of depth. Vertical lines represent the limits of the range of Be/Mn ratios in hydrothermal end members from Guaymas Basin.

Be and Mn seem to be related in the pore waters of this hydrothermally influenced environment—the correlation coefficients for cores 1172-2 and 1174-3 are 0.757 and 0.746 respectively. As shown in Fig. 3, several samples from core 1172-2 have Be/Mn ratios well within the range of Be/Mn ratios in hydrothermal fluids from the Guaymas Basin[15]: $(219 \pm 115) \times 10^{-6}$.

These observations suggest a near quantitative co-precipitation of beryllium with the hydrothermal precipitates formed near the vent during the mixing of reduced hydrothermal fluids with oxidizing sea water[4]. A pair of water-column profiles of Be in the Guaymas Basin[17], taken directly over an active vent (12 CTD) and about 1 km away from the region of active vents (11 CTD), also implies that the efficiency with which Be is scavenged near vents restricts the dispersal of hydrothermally derived ^{9}Be to within a few kilometres from the source. The general decrease of the pore-water Be/Mn ratio with depth in the sediments at Guaymas indicates that the beryllium solubilized during diagenesis of these precipitates is partitioned onto sediments more efficiently than the manganese. Although the interstitial-water chemistry of core 1172-2 indicates no advection of hydrothermal fluids[4], the maximum observed at 11 cm may be a result of enhanced hydrothermal influence. Thus, lateral and vertical fluctuations in the Be/Mn ratio may reflect the spatial and temporal variability of hydrothermal inputs for surficial sediments.

In a study[1] of the potential use of the non-detrital ^{10}Be/^{9}Be ratio for dating marine sediments, Bourlès *et al.* invoked sedimentary diagenesis and the input of hydrothermally derived ^{9}Be, among other possibilities, to explain the observed deviation from the expected decay. This work suggests that these processes do not influence the Be isotopic composition of deep-sea sediments. Nevertheless, beryllium released to pore fluids, probably during the dissolution of amorphous biogenic silica, results in fluxes out of the sediments at the oxic and suboxic sites that are large enough to support the near-bottom increases observed in the water column. Beryllium scavenged by hydrothermal precipitates in the vicinity of submarine hydrothermal vents is also released to pore water by diagenetic reduction in the sediment column. The influence of hydrothermally derived Be is, however, limited to within a few kilometres of the source because of its rapid removal. □

A new self-organizing mechanism for deep-focus earthquakes

H. W. Green II & P. C. Burnley

Department of Geology, University of California, Davis, California 95616, USA

THE mechanism of deep-focus earthquakes has been a puzzle since their discovery almost 70 years ago[1,2], because brittle fracture and frictional sliding at depths in excess of 100–200 km would require unrealistic rock strengths[3,4]. Rock strength does increase with pressure, but a few hundred MPa (equivalent to 10–20 km depth) suffices to inhibit most fracture, and elevated temperature activates ductile mechanisms that operate at stresses less than the fracture stength. A range of mechanisms has been proposed for deep earthquakes, including plastic instabilities[5–7], shear-induced melting[8–11] and instabilities accompanying recrystallization[12,13] or polymorphic phase transformation[14–23]. Each of these proposed mechanisms has exhibited certain inherent weaknesses (see Kirby[22] for review and discussion). Here we report experimental observations of high-pressure faulting of metastable Mg_2GeO_4 olivine as it undergoes incipient transformation to a spinel[24,25] structure. We present a model in which this faulting arises from the generation, propagation and linking-up of spinel-filled anticracks[26]. When applied to the olivine → spinel transformation in the Earth's mantle, the anticrack model[27] satisfactorily accounts for the similarities and differences between shallow and deep earthquakes and removes the problems associated with frictional sliding.

Most previous models of deep earthquakes postulate *a priori* the existence of a planar structure (physical or thermal) that is inclined to the principal axes of stress and which evolves into the fault. By contrast, the microstructures of our specimens suggest a new, self-organizing mechanism that is intimately

connected to the transformation process and which exhibits striking analogy to the Griffith theory of brittle fracture.

Direct experimental evidence that may bear on the origin of deep-focus earthquakes has been meagre[22,23]. Both previous studies proposed rapidly running phase transformations to explain their observations but neither involved phases expected to be present in the Earth's mantle. The process producing deep earthquakes proposed in both studies involves similar phenomena. In particular, Kirby[22] proposed that initiation of transformation to a denser phase in a planar zone under shear stress could stimulate runaway transformation in that plane, leading to faulting. The faulting that we have found to develop during the olivine→spinel transition is directly relevant to the Earth's interior and confirms the concept of a shearing instability triggered by phase transformation[18,22]. Moreover, our experiments have two important and unforeseen characteristics that provide insight into the physical mechanism responsible for the instability. First, faulting occurs only in a narrow temperature interval[24,25] where incoherent nucleation and growth becomes just possible on the timescale of the experiments[25,28]; the material is ductile both above and below this region. Second, under the conditions of instability, lens-shaped regions of very fine-grained spinel develop at high angles to the maximum compressive stress, σ_1; this morphology is distinctly different from that which develops when the transformation occurs under hydrostatic pressure. Based on these observations we propose a simple mechanism that makes the existence of deep earthquakes and their distribution not only plausible but expected.

The conditions of our experiments fall into three categories (Fig. 1). At low temperatures, the specimens are strong and ductile; martensitic (shear-induced) nucleation of spinel is possible (under sufficiently high stresses) but growth of the nuclei is kinetically inhibited[28] and faulting does not occur. At high temperatures, abundant incoherent nucleation and rapid growth of spinel are observed[25,29] and the specimens are weak and ductile[25]; again, the specimens show no instability. The intervening narrow temperature interval marks the onset of diffusion-assisted growth of martensitic nuclei[28] and also the beginnings of incoherent nucleation[25]; within this window, faulting occurs in every experiment except those purposely stopped early. Increasing the strain rate to 10^{-3} s^{-1} shifts the window to higher temperatures[25].

Optical and electron microscopy of specimens deformed within the window of instability show the following: (1) lenses of spinel develop with a very strong preferred orientation at angles to σ_1 approaching 90° (Fig. 2*a*); (2) spinel within the lenses is invariably very fine-grained (Fig. 2*b*); (3) spinel lenses sometimes develop in en echelon arrays that lie in orientations

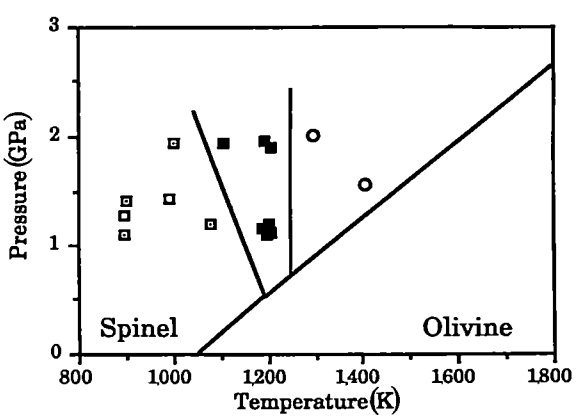

FIG. 1 Conditions of experiments conducted at strain rates of 10^{-4}–10^{-5} s^{-1} on metastable Mg_2GeO_4 olivine Open squares represent specimens that were strong and ductile, open circles, specimens that were weak and ductile, and closed squares, specimens that failed. See text for discussion. Phase boundary after ref. 42.

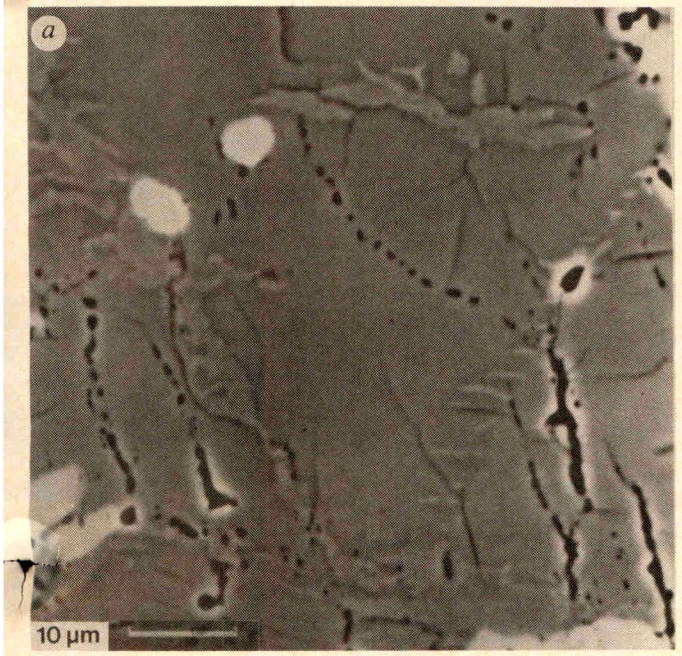
of high shear stress (Fig. 2*c*); (4) unfaulted specimens, including those in experiments stopped just after onset of the instability (but before faulting), show no growth of spinel in planes of high shear stress; (5) faults contain fine-grained spinel[25]; (6) en echelon microfaults occur with stepping in the opposite sense to that commonly observed in brittle faulting (in one experiment, small spinel-lined faults are linked by push-togethers exhibiting enhanced transformation in the form of spinel microlenses, whereas in brittle behavior, faults are linked by pull-aparts[30]).

The crack-like morphology of the spinel lenses coupled with their preferred orientation normal to σ_1 reminds us of the anticrack model[27] of stylolites (solution surfaces). The term 'anticrack' was devised because anticracks are identical to tension (mode I) cracks except that the algebraic signs of the displacements and stresses around them are reversed. Consider a solid with a small planar flaw that is acted upon by a macroscopic tensile stress σ_3 (Fig. 3*a*). Under the stress, the flaw becomes an open mode I crack with zero stress across it and high tensile stress at its tips. Similarly, if one imagines a lenticular void (of the dimensions of the crack in Fig. 3*a*) within an unstressed solid and applies a far-field compressive stress, σ_1, just sufficient to close the void, one obtains an 'open' mode I anticrack with zero stress across it and high compressive stress at its tips (Fig. 3*b*). If the crack is not normal to σ_3, its tips deviate during growth so as to approach that orientation[31,32]. Similarly, if an anticrack is not normal to σ_1, it will become so during growth (by dissolution in the case of stylolites). This is the model of stylolites in ref. 27, which captures the essence of their shape, orientation and geological setting.



Here we extend the analogy between cracks and anticracks to encompass filled versions of the two. We consider a small lenticular volume within a solid that undergoes a phase transformation. If the transformation involves a volume increase, the resulting stress distribution will be as shown in Fig. 3*c*. Similarly, if the phase change leads to densification (as does the olivine→spinel transformation), the stress distribution will be as shown in Fig. 3*d*. Superposition of a tensile stress on Fig. 3*c* or a compressive stress on Fig. 3*d* will enhance the effects at the tips while relieving the stresses across the surfaces of the lens, leading to stress distributions similar to those of Figs 3*a* and *b*. In all cases, the magnitude of the stress concentrations is controlled primarily by the curvature at the tips; the more pointed the tip, the higher the stress concentration. The tendency for the tips of a propagating filled anticrack to rotate toward the plane normal to an applied compressive stress is the same as for an empty anticrack. In this case it does so by enhanced transformation to the stable phase(s) as a result of the high compressive stresses at the tips. The rheology of the filling material will become critical should a shearing instability develop. The orientation and the striking crack-like morphology of the spinel lenses in our specimens lead us to conclude that they are mode I anticracks with these characteristics.

Under fluid-absent conditions, tensile microcracks are closed by application of pressure, and tensile (mode I) failure is inhibited; brittle failure occurs by generation of large numbers of mode I microcracks and development of an instability which leads to shear (mode II) fracture. The fundamental process by which the mode I (Griffiith) microcracks propagate and link together to produce faulting is poorly understood because mode II cracks do not propagate in their own plane[31,32]. Petit and Barquin[32] concluded that "mode II cannot exist as an elementary (primary) fracture mechanism but can only be a macroscopic fracture phenomenon which must necessarily involve tensile (mode I) microcrack formation". This description of brittle failure is remarkably similar to our observations in that we see abundant mode I anticracks but no evidence of shear failure in advance of macroscopic faulting. We therefore propose that shear failure in our experiments occurs by anticracking, with the generation and linking of mode I features being analogous to similar processes occurring in normal brittle failure. The

instability is not a friction-related phenomenon, however, because the fine-grained nature of the spinel produced under these conditions renders it superplastic[33]. As a consequence, the mechanism is not inhibited by high pressure.

For application of this mechanism to deep faulting within the Earth, we first must consider the differences between the germanate system of our experiments and the silicate system of the mantle, and the distribution and characteristics of deep earthquakes. Germanates have been shown to be faithful analogues for silicates, especially with respect to the olivine→spinel transition[28,34]. Our experiments on Mg_2GeO_4 relate only to the $\alpha \rightarrow \gamma$ transformation, however, whereas in the Earth the transformation in $(Mg, Fe)_2SiO_4$ olivine will be $\alpha \rightarrow \beta$ or $\alpha \rightarrow \gamma$ depending on the conditions at which the phase transition occurs[35]. As anticracks are driven only by volume reduction under stress and because the β phase also is more dense than olivine, our mechanism should apply equally to either transformation.

Figure 4*a* shows the depth distribution of earthquake frequency in descending slabs of lithosphere beneath island arcs[36] and Fig. 4*b* shows a model of the temperature distribution expected in such slabs along with the accompanying perturbation of the equilibrium boundary for the olivine–spinel transformation[37]. Our results indicate that in the central, colder parts of the slab the transformation is kinetically inhibited until it reaches a set of critical conditions at which nucleation and growth of spinel become possible. The critical conditions depend on the presence of a nonhydrostatic stress and on the temperature, the timescale on which the stresses are applied, the degree of overstepping of the phase boundary (and hence the pressure) and the amount and rate of plastic deformation imposed on the metastable olivine. The onset of the transformation is controlled by kinetic factors and therefore temperature and time are the most important parameters, just as they are in our experiments. Therefore, for simplicity of presentation, we will discuss the possibility of earthquakes in terms of a critical temperature at which nucleation and growth become just possible on the timescale involved. Neglecting any depth dependence of the critical temperature T_c we see that if, for natural olivine, $T_c = 1{,}300$ K for the hypothetical slab in Fig. 4*b*, the olivine→spinel transformation could be responsible for all deep earthquakes. Alternatively, if $T_c = 1{,}200$ K, olivine→spinel

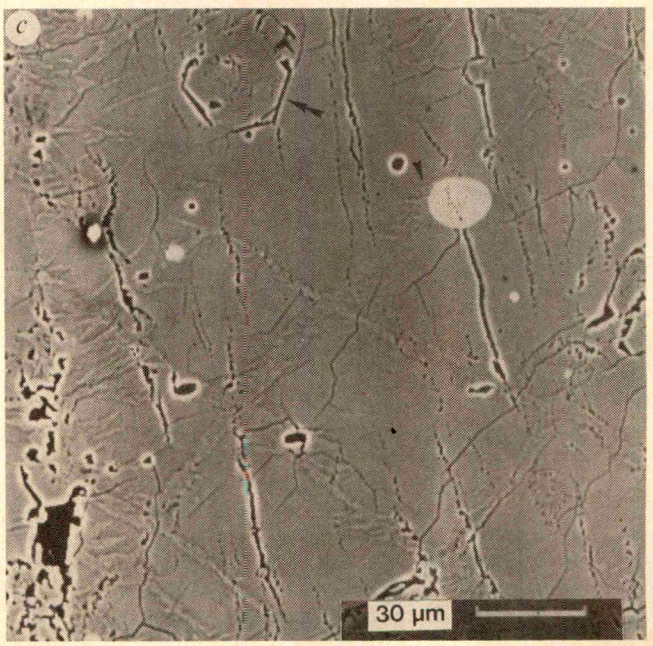


FIG. 2 Microstructures of faulted specimens; the maximum compressive stress σ_1 is vertical in all micrographs. *a*, Backscattered-electron (BSE) scanning electron micrograph of a polished specimen showing transformation of α-Mg_2GeO_4 (olivine) to γ-Mg_2GeO_4 (spinel). The spinel phase (light grey) nucleates on the grain boundaries between olivine crystals (dark grey) and on pyroxenes (white); it grows as thin lenses, the long axes of which exhibit a strong preferred orientation normal to σ_1. Black regions (that often appear as dotted lines) are quench cracks that have been partially filled by the syton polishing process. *b*, Secondary-electron scanning electron micrograph of a specimen etched in HCl to enhance visibility of spinel. The surface mottling of the spinel lenses (white) is due to dissolution at grain boundaries and shows that they are composed of equant, very fine-grained (<1 μm) crystals. *c*, BSE micrograph of a polished specimen showing intersecting arrays of en echelon spinel lenses within a single crystal of olivine and abundant growth of lenses on a grain boundary (left). Lenses also can be seen growing off of a pyroxene inclusion (single arrowhead). The large, equant, faceted crystal near the top (double arrowheads) is a cube-modified octahedron of spinel with the topotaxy expected for the martensitic nucleation mechanism[28]. The crystallographic control of the habit of crystals nucleated by coherent mechanism and the nucleation of lenses on inclusions and grain boundaries suggest that the lenses are the result of the incoherent mechanism.

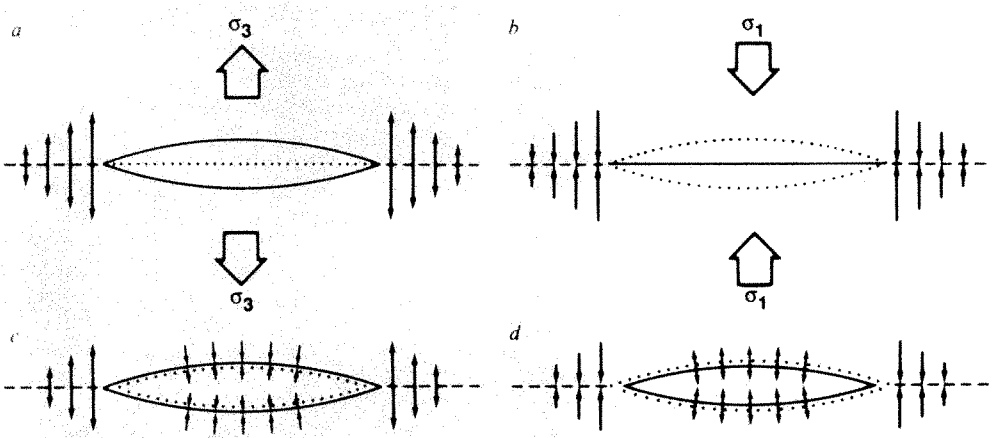

FIG. 3 Comparison of mode I cracks and anticracks. *a*, A small planar flaw in a solid across which cohesion has been lost (dotted line) is pulled open by a remote tensile stress, σ_3, yielding a lens-shaped void (crack) with tensile stress concentration at its tips. *b*, A small lenticular void (dotted) in a solid is pushed closed by a remote compressive stress, σ_1, yielding a compressive stress concentration at its tips. The stress distribution is identical that in *a* except that the algebraic signs have been reversed. This is an empty anticrack. *c*, Local phase transformation of a lens-shaped volume (dotted) in an unstressed solid that expands on transformation. The enlarged lens has compressive stresses across its surfaces and tensile stresses at its tips. *d*, Phase transformation to a denser phase in a lens-shaped volume (initial dimensions dotted) leads to a stress distribution the inverse of that found in *c*. This is a filled anticrack. For the application of interest in this paper, we superpose onto the stresses shown in *d* a far-field nonhydrostatic stress for which the mean stress $(\sigma_1+\sigma_2+\sigma_3)/3$ is of the order of 1–2 GPa for our experiments and 8–18 GPa for the Earth. We arrive at a system with a lens of spinel embedded in olivine with the (compressive) normal stress across the lens less than the macroscopic normal stress in that direction and with enhanced compression at the tips.

would be exhausted as a mechanism by ~600 km and another transformation such as spinel → perovskite + magnesiowüstite) would be needed for deeper earthquakes. Although we do not yet know the T_c for natural olivine under mantle conditions, these temperatures are within the range proposed[38] for the onset of transformation in mantle olivine. It is therefore clear that the known thermal structure of descending slabs makes it unavoidable that material within subducting lithosphere must encounter conditions appropriate for the kind of instability that we propose, unless the stresses are too low for faulting.

Although it is not yet clear how incoherent nucleation and growth can operate at rates sufficient to generate faulting, our results suggest that anticracks and the shear instability are unrelated to the martensitic nucleation mechanism (Fig. 2*c*). We postulate that the instability follows development of a critical density and/or distribution of mode I anticracks and incipient loss of coherence of the olivine framework; catastrophic failure follows when, during the first stages of collapse, the heat generated locally by transformation at points of stress concentration causes the next increment of reaction to be faster, leading to runaway of transformation in a narrow zone. It is encouraging that deep earthquakes seem to be relatively slow — "The times and distances to rupture subevents indicate that the failure process propagates with a speed which is less than the S wave speed"[39].

Our model also predicts that faulting should not occur repeatedly in the same material because the transformation process is intimately involved in the faulting. That is, repeated stick-slip is not to be expected because after faulting the fault zone is lined with superplastic spinel that should be ductile. That is what we see in our experiments[25] and it is also consistent with the seismic data; the aftershock distribution of deep-focus events is incompatible with simple slip on a single fault[39]. After some time, the spinel within the fault zone should coarsen, lose its superplastic properties, and may become stronger than olivine, preparing the way for further faulting nearby.

Unless a fluid is produced, this, or any other, phase-transformation mechanism cannot explain earthquakes at depths <250–300 km because there are no known appropriate solid-solid transformations that could occur in an interconnected phase of peridotite, basalt or eclogite. The depth distribution shown in Fig. 4*a* suggests[40] a superposition of two distinct varieties of seismic activity. We are tempted to decompose the data into two distributions and attribute the shallow component to failure

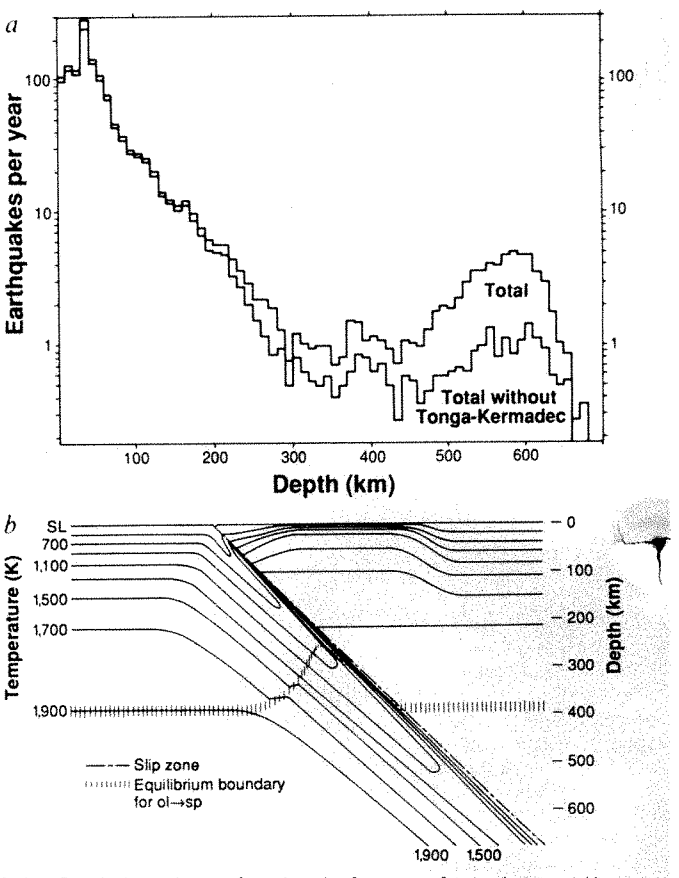

FIG. 4 *a*, Depth dependence of earthquake frequency for moderate and large earthquakes during the period January 1964–February 1986 for the entire Earth (Total) and for the Earth except for the Tonga and Kermadec subduction zones (after ref. 36). Note exponential falloff to 300 km, marked increase again to 550–600 km and abrupt cutoff below 650 km. *b*, Thermal model of descending slab of lithosphere (after ref. 37) showing shape of isotherms and distortion of equilibrium olivine–spinel phase boundary. Temperature contours ≥1,500 K are depicted assuming that the transformation occurs (aseismically) with negligible overstepping of the phase boundary. For lower temperature, the contours pass through the equilibrium boundary unperturbed, implying that the transformation is delayed. Any volume of material in the cold interior of the slab must inevitably encounter the conditions of mechanical instability discussed in the text.

by cracking and the deep component to failure by anticracking. The exponential drop-off of the shallow component might be due to fluid-assisted cracking (Terzaghi effect)[41] down to depths of perhaps 250 km; the similar rapid rise of the deep component is consistent with faulting by anticracking in response to increased overstepping of the olivine→spinel phase boundary at greater depths. Faulting finally falls off rapidly at depths >650 km as the spinel→perovskite+magnesiowüstite transformation is completed and no other transformations are available[22]. □

Perception of multiple transparent planes in stereo vision

Daphna Weinshall

Center for Biological Information Processing, Department of Brain and Cognitive Sciences, Massachusetts Institute of Technology, E25-201, Cambridge, Massachusetts 02139, USA

INFORMATION about the distances of objects that we see can be obtained from the disparity in position of their images in our two eyes. This process entails solving the problem of stereo-matching, which involves the determination of which points in the two images correspond to the same object. This is particularly problematic when features in the visual field are repeated, allowing more than one possible solution to the stereo-matching problem. Here I describe a situation in which a repetition of a random dot pattern leads to the perception of multiple transparent planes under some conditions, and of a single opaque plane under other conditions. This result shows that stereo-matching is not necessarily unique—a given point of the image in one eye may be matched simultaneously to more than one point in the other eye, each match defining a different depth plane. Current stereo-matching algorithms in computer vision do not account for these observations.

The stereoscopic matching of points in images involves a difficult computation, as shown in Fig. 1*b*. Here the two bars in the left image can be matched to the two bars in the right image

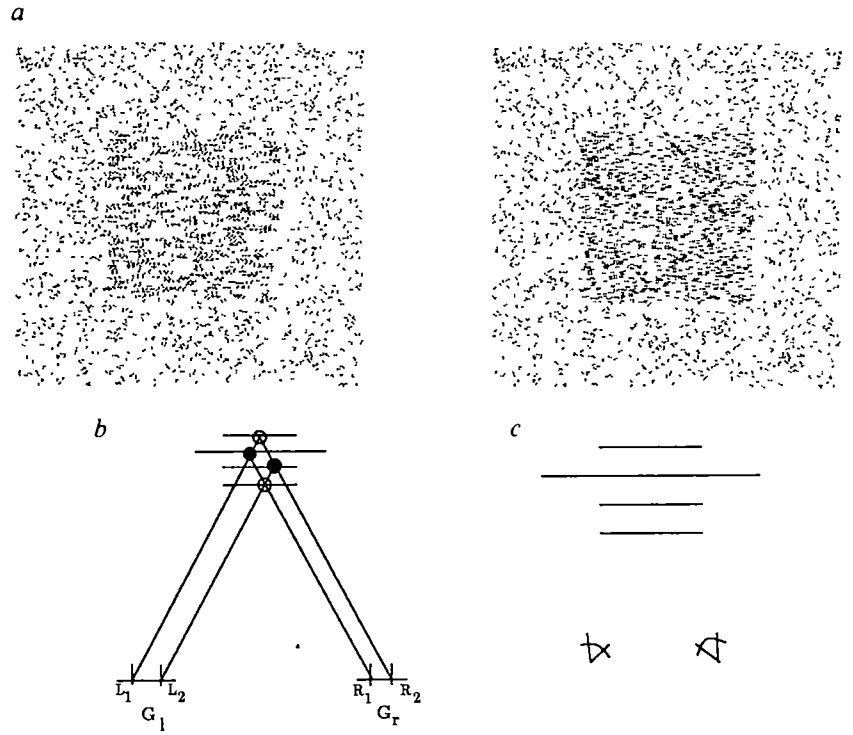

FIG. 1 *a*, An ambiguous stereogram with G_r=10′ and G_l=20′ After some time four planes emerge two in front of the background, the background (all three transparent), and one behind the background The deepest plane is often difficult to see, it helps to slightly diverge the eyes to capture it Note the two bars ('nails') in the middle of the stereogram, which are usually seen on the two middle surfaces only, and which are hard to flip to the other surfaces. Because it takes some time for the impression to build, it is recommended to use a stereo viewer ~12.5-15.5 cm high. *b*, A graphic illustration of the projections of the two bars from the stereogram in *a*. The two pairs of matches that are mutually exclusive if matching is unique are separately marked by filled and hollow circles. This is also an illustration of the stimulus in the double nail illusion, where two nails are placed one behind the other with respect to the viewer The resulting stereo pair looks like *b*, except that the ghost matches are in fact the correct ones Humans, however, seem to prefer the order-preserving matches, and see an illusory percept of two nails side by side at the same depth[3] *c*, The depth profile of the four possible matches of the stereogram in *a* Braddick has used related stereograms (unpublished results; also see ref 10) with effectively G_r=0 (or G_l=0).

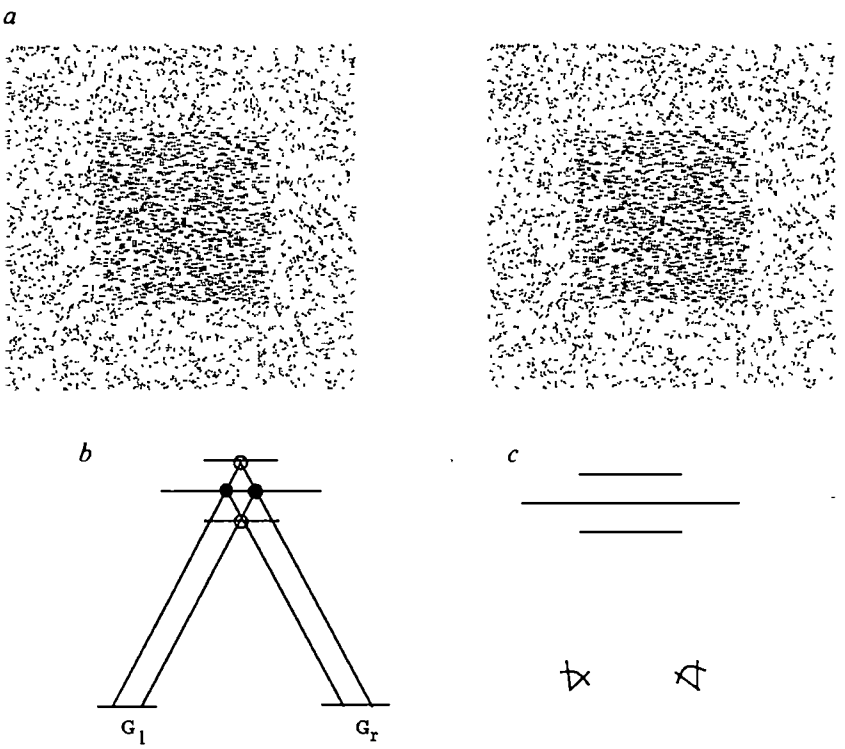

FIG 2 *a*, An ambiguous stereogram with $G_r = G_l = 10'$. Here only one opaque surface is seen, the background, and no vergence can help detect the other two surfaces (one above the background and one below it). *b*, A graphic illustration of the projections of two points from the stereogram in *a* c, The depth profile of the three possible matches of the stereogram in *a*.

in four different ways. Two of these correspond to the matching of the left bar in the left image to the left bar in the right image, and the matching of the right bar in the left image to the right bar in the right image. These order-preserving matches are generally presumed to be correct[1,2]. The other two matches are the 'ghost' or false matches. Humans seem to prefer the order-preserving matches even under experimental conditions where the ghost matches are in fact the correct ones (the double-nail illusion shown in Fig. 1*b*, see also ref. 3). The ambiguity of matching is higher with random dot stereograms, where each point has many false matches in the other image (see Fig. 1*a*). Matching algorithms are usually meant to resolve such ambiguities and to obtain a unique correspondence (for example, see refs 4 and 5).

To test whether matching in human vision is always unique, I used an ambiguous random dot stereogram, which is an extension of the double-nail illusion. This was generated by first computing a random dot pattern, which was then copied twice in each image, with a different horizontal spacing of G_r minutes of arc in the right image and G_l minutes of arc in the left image (Figs 1*a* and 2*a*). The random pattern background was identical in both images. Observers who could fully fuse these stereograms saw four transparent surfaces corresponding to all the four possible matches shown in Fig. 1*b* (with the help of vergence

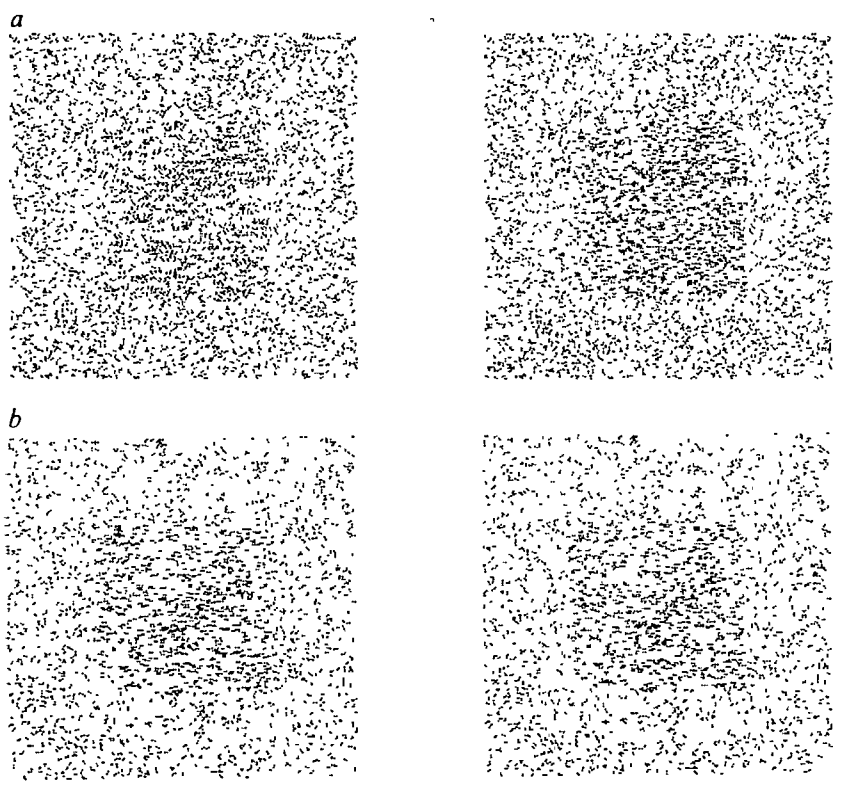

FIG 3 *a*, As in Fig 1*a*, where the number of points in the deepest plane have been doubled with new unambiguous points *b*, As in Fig. 2*a*, with an additional new uncorrelated plane at disparity 20', twice the disparity of the suppressed planes (10' and −10')

and memory; vergence is often needed in the perception of transparent stereograms[6]). These observers could judge the depth of the ghost surfaces correctly. This perception is unlike the perception of only two matches with single features (the double-nail illusion).

This result indicates that all sufficiently strong disparities give rise to the perception of distinct transparent surfaces. I define the strength of a given disparity at a given pixel to be the value of the correlation function between the two images (see Fig. 4 legend). A sufficient strength is a correlation value that is sufficiently above random. I call the corresponding disparity a 'solution'. To test the above hypothesis I used a special case of the stereogram that was used in the first experiment, in which $G_r = G_l$ (see Fig. 2). In this case there are three possible solutions (Fig. 4*b*). One might expect to see three transparent planes, by analogy with the first experiment. Surprisingly, only the strongest solution was seen, and this perception was quite robust.

Perhaps only solutions with approximately equal strength, that is, with comparable maxima in the correlation function, are detected, whereas weaker solutions are suppressed. To test this hypothesis I used the initial stereogram, in which $G_r \neq G_l$, but the amount of points in one plane was doubled by adding unambiguously matched points. All four solutions were still seen (Figs 3*a* and 4*c*). The other surfaces were visible even when the number of points in one surface was quadrupled.

The suppressed planes of Fig. 2*a* could be made to reappear for some observers. Either the number of points in each image was doubled by adding unmatched random dots, or correlated points were added to both images, forming a new plane (see Figs 3*b* and 4*d*).

The independent local selection of one of the possible ambiguous matches cannot by itself explain why the ambiguous planes were suppressed in Fig. 2 and visible in Fig. 1. I will now briefly outline a computation scheme that is consistent with these results. Initially, surfaces are constructed that take into account all possible matches of all the pixels. Let the support set of a surface be the set of points within a window of size W in one image, which contribute to its construction. Assume W is large enough so that random matches occur at all disparities. A surface is retained it is has a sufficiently large support set that is not included in the support set of a different surface. With simple transparencies (see refs 7 and 8) all possible solutions survive, as their support sets are disjoint. In the stereogram of the first experiment (Fig. 1) all four solutions survive because part of the support set of each solution is derived from random matches (as shown by the fact that the peaks in Fig. 4*a* are ~10% greater than the value of 0.5 expected from the strict matches shown in Fig. 1*b*). In the stereogram of experiment 2 (Fig. 2), the strong solution suppresses the others because its support set includes all the points in any region.

The main implication of the above discussion is that the resolution of matching ambiguities is not as simple as nearly all the computational theories of stereo vision assume. A unique solution is a stated objective of these theories. My results require their extension to describe surface interpolation, which allows and uses multiple matchings. Possibly, the processes involved in feature matching and the resolution of ambiguities are different from those involved in surface interpolation (see ref. 9). □

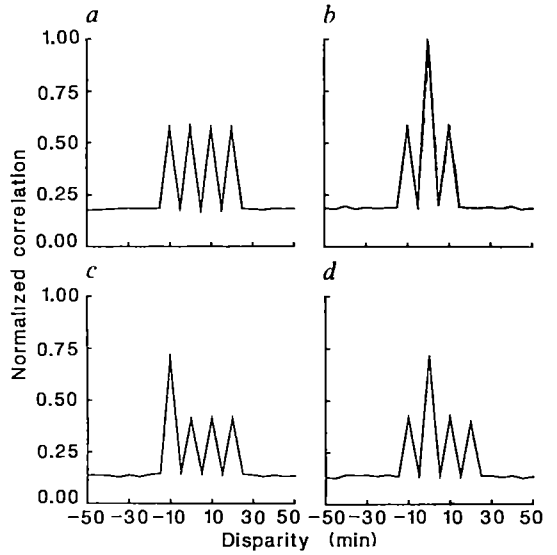

FIG. 4 The normalized correlation between the left and the right images at their centre. $\sum_i^W \sum_j^W I(x_i^R, y_j^R)I(x_i^L + D, y_j^L)$. The *x*-axis is the disparity *D*: *a*, Stereogram of Fig. 1; *b*, stereogram of Fig. 2; *c*, Stereogram of Fig. 3*a*; *d*, stereogram of Fig 3*b*. The size of the window *W* is the width of the ambiguous square at the middle of each image. The correlation value is normalized by the number of features in the window so that it equals 1 if all the points are matched for some disparity value. These plots have been computed for stereogram with dot density of 10%. The noise level (10% in *a*) increases with dot density. Note that only in *b*, the only case where a single opaque plane is perceived, has one of the possible solutions a normalized disparity value of 1. This observation indicates a way to modify an area-based correlation stereo-matching algorithm to give the above results (for example, see ref. 11).

Arachidonic acid induces a long-term activity-dependent enhancement of synaptic transmission in the hippocampus

J. H. Williams, M. L. Errington, M. A. Lynch & T. V. P. Bliss

Division of Neurophysiology and Neuropharmacology, National Institute for Medical Research, Mill Hill, London NW7 1AA, UK

LONG-term potentiation (LTP) is a widely studied model of the synaptic basis of information storage in the mammalian brain[1,2]. The induction of LTP is triggered by the postsynaptic entry of calcium through the channel associated with the *N*-methyl-D-aspartate (NMDA) receptor[3–7], whereas its maintenance is mediated, at least in part, by presynaptic mechanisms[8–12]. To explain how postsynaptic events can lead to an increase in transmitter release, we have postulated the existence of a retrograde messenger to carry information from the postsynaptic side of the synapse to recently active presynaptic terminals[10]. Candidates for a retrograde messenger include arachidonic acid or one of its lipoxygenase metabolites[12–18]. Here we report that weak activation of the perforant path, when given in the presence of arachidonic acid, leads to a slow-onset persistent increase in synaptic efficacy both *in vivo* and *in vitro*. The activity-dependent potentiation thus produced is accompanied by an increase in the release of glutamate, and is

non-additive with tetanus-induced LTP. These observations indicate a role for arachidonic acid as a retrograde messenger in the later, but not the initial, stages of LTP.

A push–pull cannula was used to perfuse the dentate gyrus in anaesthetized rats, while recording extracellular synaptic potentials evoked by test stimuli delivered to the perforant path. Addition of arachidonic acid (200 μM) to the artificial cerebrospinal fluid for 35 min usually caused a slight and reversible depression of the population excitatory postsynaptic potential (e.p.s.p.), but did not produce long-term after-effects (Fig. 1*a*). In another group of animals, weak high-frequency trains, which given alone were subthreshold for the induction of LTP (Fig. 1*b*, first arrow), were repeated 5 min before the end of a 35 min period of perfusion with arachidonic acid (Fig. 1*b*, bar and second arrow). In all cases, the conjunction of weak trains and perfusion with arachidonic acid resulted in a slowly developing increase in the slope of the population e.p.s.p. The average potentiation (±s.e.m.) 2 h after conjunction, calculated from the normalized mean values plotted in Fig. 1*b*, was 68.7 ± 14.7% (range 14.7–158.0%, $n = 7$). In another two animals, in which the initial weak train was omitted, the potentiation produced by conjunction persisted without decrease for 4 h (Fig. 1*c*). No potentiation occurred when the second train was given in the absence of arachidonic acid (data not shown).

To examine the possibility that a lipoxygenase metabolite of arachidonic acid, rather than arachidonic acid itself, is the active compound in producing potentiation, we applied a weak tetanus in the presence of arachidonic acid and the lipoxygenase inhibitor nordihydroguaiaretic acid (NDGA, 200 μM). The slow-onset potentiation was not affected and reached a magnitude, when measured 2 h after the weak tetanus, that was comparable to that seen in the tetanus–arachidonic acid group (Fig. 1*d*; 63.2 ± 32.2%, range 14.9–81.2%, $n = 4$). An analogous result was obtained in the *in vitro* hippocampal slice preparation. These experiments indicate that it is arachidonic acid itself, rather than its lipoxygenase metabolites, that is important in generating the late potentiation. In four animals we examined the effect of AP5 (D(−)-2-amino-5-phosphonovalerate), an antagonist of the NMDA subtype of glutamate receptor and a potent blocker of the induction of LTP[3,11]. When AP5 (100 μM) was included in the perfusion medium during the period of perfusion with arachidonic acid, a similar slowly developing potentiation occurred after the weak tetanus (data not shown). We conclude that potentiation induced by arachidonic acid is not mediated by the NMDA receptor/channel.

The mean increase in the slope of the e.p.s.p. produced by the conjunction of weak stimulation and arachidonic acid is within the range of maximal LTP in this preparation[19]. The question arises whether the two effects exploit similar cellular mechanisms at some stage subsequent to the opening of the NMDA channel. We tested this possibility by occlusion experiments in four rats (Fig. 2). When strong tetani were given during the plateau phase of arachidonate-induced potentiation, there was no additional potentiation (Fig. 2*a*). In the converse experiment, maximal LTP was first induced by three episodes of strong tetanic stimulation. Arachidonic acid was then added to the perfusion medium and a series of weak tetani applied. There was no further increase in the slope of the e.p.s.p. (Fig. 2*b*). These observations imply a convergence in the sequence of events leading to potentiation in the two cases.

A similar persistent potentiation of synaptic efficacy was produced in the dentate gyrus of the hippocampal slice by the conjunction of arachidonic acid and weak activation. Because of the difficulty in establishing tetanus-induced LTP in the perforant path *in vitro*[20], we adopted an activation protocol in which the frequency of stimulation was increased from $\frac{1}{30}$ Hz to $\frac{1}{4}$ Hz for a 30 min period. With normal perfusion medium, stimulation at $\frac{1}{4}$ Hz caused an habituation[21] of the response, which was only partially reversible (Fig. 3*a*). Addition of arachidonic acid (50 μM) to the medium without increasing stimulus

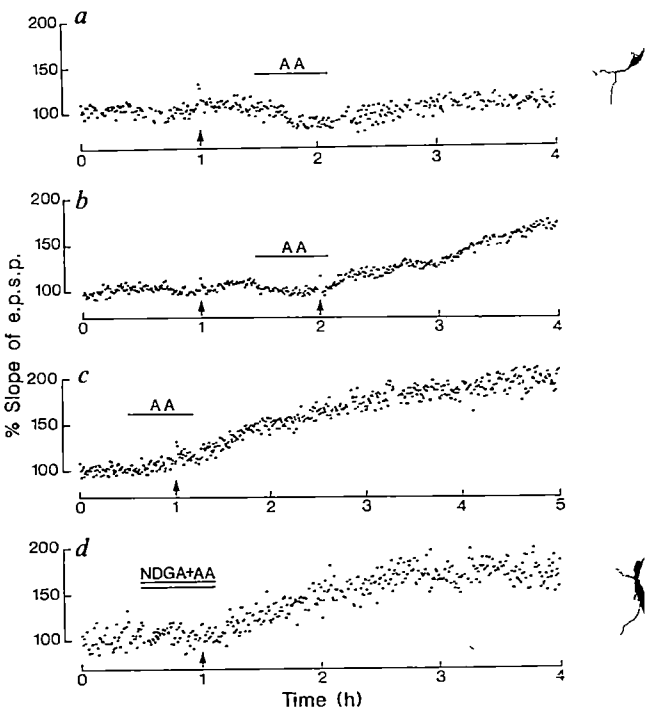

FIG. 1 Perfusion of arachidonic acid (AA) causes an activity-dependent potentiation of synaptic transmission in the dentate gyrus of the anaesthetized rat. *a–d*, Slope of the population e.p.s.p., recorded in the granule cell layer in response to stimulation with weak test shocks of the perforant path at $\frac{1}{30}$ Hz, is plotted against time. Values are normalized with respect to the mean e.p.s.p. slope for the 20 responses at the end of the first 60 min (*a*, *b*) or the first 30 min (*c*, *d*). The experimental design required the delivery of weak tetani that were subthreshold for the induction of LTP in normal medium; that this was the case was checked in the first part of the experiment (first arrows in *a*, *b*). *a*, Arachidonic acid alone (200 μM) causes only a transient depression of the evoked response. Plot of the mean normalized e.p.s.p. in a group of three experiments in which no tetanic stimulation was given during the period of perfusion with AA (bar). *b*, Weak tetanus given in the presence of 200 μM AA (bar) results in a slowly growing potentiation. The mean of seven experiments in which the first tetanus produced a potentiation of less than 10% is plotted. Note the slow onset and gradual climb towards a plateau in the 2-h period after the weak train. *c*, Mean of two experiments in which the potentiation produced by the conjunction of AA and a weak tetanus was followed for 4 h. *d*, Slow-onset potentiation produced by weak tetanic stimulation and AA (200 μM) in the presence of NDGA (200 μM). Mean of four experiments.

METHODS. Adult Sprague-Dawley rats were anaesthetized with urethane (1.5 g kg^{-1}, intraperitoneal) and placed in a stereotaxic headholder. A push–pull cannula (outer diameter 0.83 mm) with a pair of attached wire recording electrodes, was advanced into the dentate gyrus, so that the cannula straddled the molecular layer, with one recording electrode in the molecular layer and the other in the granule cell layer[9]. A bipolar stimulating electrode was advanced into the angular bundle to activate afferent fibres of the perforant path. Weak test shocks were alternated with stronger test shocks, above threshold for eliciting a population spike, so that changes in amplitude of the population spike could be monitored (not shown). Weak tetani consisted of three trains of stimuli (250 Hz for 200 ms, 60-s intertrain interval) at the same intensity as the weak test shocks. Responses were sampled digitally and stored on disk for later analysis. Artificial cerebrospinal fluid (ACSF, composition in mM: NaCl, 136; KCl, 2.54, KH_2PO_4, 1.2; $CaCl_2$, 1.8; $MgSO_4\,7H_2O$, 1.18; $NaHCO_3$, 23; glucose, 10) was gassed with 95% O_2, 5% CO_2 and perfused throughout the experiment at 6.5 μl min^{-1}. A period of 1 h elapsed between the beginning of perfusion and the collection of evoked potentials to allow the system to stabilize. AA (Sigma) was dissolved in ethanol by sonication. Aliquots, 1 mM in ACSF, containing ascorbic acid, were stored at −70 °C. For perfusion, aliquots were diluted in ACSF to a final concentration of AA, 200 μM; ascorbic acid, 100 μM, ethanol, 1%. Vehicle alone had no activity-dependent effects on evoked responses either *in vivo* or *in vitro*.

frequency resulted in an initial depression, followed by a transient potentiation on return to normal medium (Fig. 3*b*). The conjunction of arachidonic acid (50 μM) and stimulation at $\frac{1}{4}$ Hz was followed by a rapid recovery from habituation and a gradual increase in the slope of the e.p.s.p. to well above control levels in the subsequent 1.5 h (Fig. 3*c*). Thus, as in the anaesthetized animal, it is the conjunction of increased activation and arachidonic acid that leads to potentiation. Despite the difference in stimulus protocols, the degree of potentiation was similar *in vitro* and *in vivo*.

We measured the release of glutamate into the perfusion medium in five of the *in vitro* experiments in which potentiation was produced by the conjunction of arachidonic acid and repetitive stimulation, and in five of the control experiments in which arachidonic acid was perfused without additional stimulation. (Similar measurements were not possible *in vivo*, because perfusion with arachidonic acid led to the appearance of blood in the perfusate, resulting in spuriously high glutamate concentrations). In the potentiated *in vitro* group, the mean glutamate concentration (±s.e.m.) increased from 35.8 ± 3.8 nM in the first hour to 46.1 ± 2.5 nM in the third hour ($P < 0.05$, *t*-test); by contrast, the concentration of glutamate in the control group showed a non-significant decline from 40.6 ± 2.4 nM in the first hour to 35.9 ± 3.6 nM in the third hour. Interpretation of this result is complicated by the fact that the Schaffer-commissural pathway was activated with stimulus patterns identical to those applied to the perforant path (see Fig. 3 legend); a similar slow-onset potentiation was induced in this pathway after the conjunction of repetitive stimulation and arachidonic acid (results not shown). As a result, it is not possible to separate the contribution made by these two pathways to the total glutamate content in the perfusate. Nevertheless, we can conclude that in area CA1, or in the dentate gyrus, or more probably in both regions, potentiation induced by arachidonic acid is associated with an increase in glutamate release.

It has previously been shown that the two predominant *cis*-unsaturated fatty acids oleic acid and arachidonic acid, prolong a short-lasting form of LTP in the perforant paths[16]. The experiments reported here demonstrate that the conjunction of exogenously applied arachidonic acid and weak afferent activation is sufficient to initiate a long-lasting increase in the efficacy of synaptic transmission in this pathway. As with tetanus-induced LTP, the enhancement of transmission is accompanied by, and is presumably at least partly due to, an increase in the release of glutamate. The occlusion experiments illustrated in Fig. 2 also indicate a convergence in the processes underlying arachidonate-induced and tetanus-induced LTP. Although our observations readily support the retrograde messenger hypothesis, according to which arachidonic acid is released from a postsynaptic site and acts on presynaptic terminals to increase transmitter release, we cannot exclude the possibility that arachidonate-induced potentiation is the result of an action on glial or postsynaptic sites. The time course of potentiation induced by arachidonic acid, with its slow onset and gradual climb towards a plateau during the 60–120 min after the washout of arachidonic acid, is in marked contrast to the rapid onset of LTP. Recent experiments with protein kinase inhibitors[22–24] and inhibitors of protein synthesis[25,26] reinforce earlier suggestions[27] that there are two or more temporal components of LTP—an early phase not blocked by protein synthesis or protein kinase

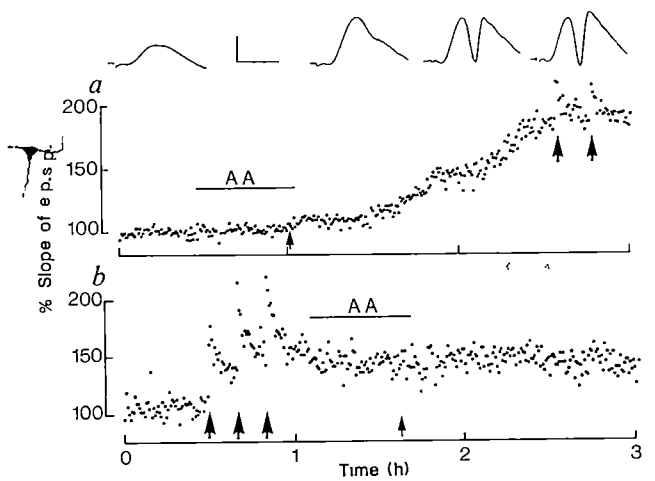

FIG 2 LTP and activity-dependent arachidonate-induced potentiation are non-additive. *a*, Experiment in which no further potentiation was obtained when strong tetanic stimulation was given after AA-induced potentiation The traces in the top panel were recorded at the times indicated by the asterisks under the abscissa Each trace is the average of five consecutive responses to weak test shocks (calibration 4 mV, 5 ms). Note the late development of a population spike *b*, Experiment in which maximal LTP was induced by a series of three episodes of strong tetanic stimulation (250 Hz for 200 ms, intensity suprathreshold for population spike, 10 min between trains) Subsequent perfusion with AA and weak tetanic stimulation failed to induce further potentiation Similar results were obtained in two other experiments.

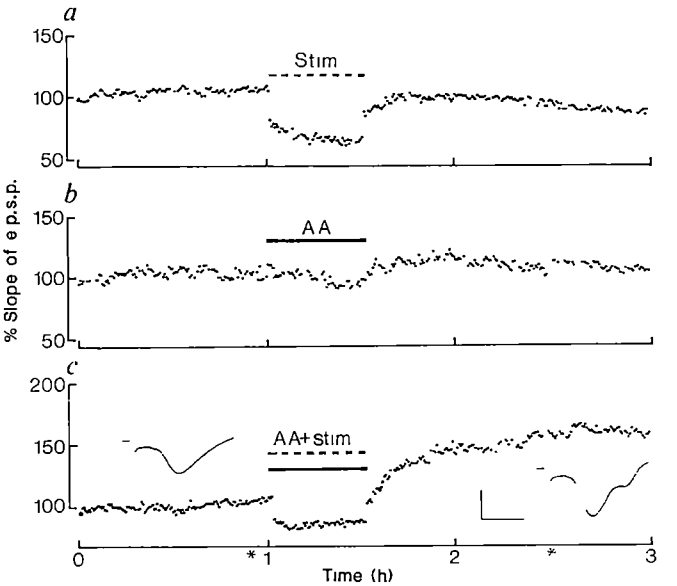

FIG. 3 Activity-dependent potentiation by arachidonic acid (AA) in the dentate gyrus of the hippocampal slice. *a–c*, slope of the population e.p.s.p recorded in the molecular layer in response to test stimuli delivered to the perforant path at $\frac{1}{30}$ Hz is plotted against time. The intensity of test stimulation was subthreshold for evoking a population spike Plots are group means, normalized with respect to the mean value of the e p.s.p. in the 20 responses at the end of the first hour *a*, Habituation produced by stimulation (stim) at $\frac{1}{4}$ Hz (stim, dashed line) in normal perfusion medium ($n=6$) *b*, AA alone (50 μM) causes a transient slight depression of the population e.p.s.p. ($n=6$) *c*, AA (50 μM) in conjunction with repetitive stimulation at $\frac{1}{4}$ Hz causes a persistent enhancement of synaptic transmission ($n=6$). The inset traces (means of five consecutive responses from one experiment) were obtained at the times indicated by asterisks under the abscissa (calibration 1 mV, 5 ms).

METHODS Transverse hippocampal slices (two per experiment) were maintained in a modified interface chamber at a temperature of 28–30 °C, and perfused with oxygenated ACSF at 100 μl min^{-1} as previously described[13] In one of the two slices (the other being held as a reserve) stimulating electrodes were placed in the perforant path and in the Schaffer-commissural fibres, and recording electrodes in the molecular layer of the dentate gyrus and in stratum radiatum of area CA1 AA was prepared for perfusion as described in the legend to Fig 1 to a final concentration of AA, 50 μM, ascorbic acid, 25 μM, ethanol, 0.25%. Evoked responses were digitized and stored on disk. Fractions of perfusate were collected every 15 min in a fraction collector packed with solid CO_2. Samples were stored at −70 °C, subsequently thawed, and derivatized with *o*-phthalaldehyde-mercaptopropionic acid Glutamate was separated from other amino acids by reverse-phase HPLC, and its concentration estimated fluorometrically with reference to a standard curve[10]

inhibitors, and a later phase blocked by both. Our results are consistent with a role for arachidonic acid as a retrograde messenger in the genesis of the later, but not the initial, component of LTP. The onset of increased transmitter release in LTP occurs not later than 15 min after the tetanus[9–12], so the present results imply either that the early phase of enhanced release is mediated by wholly presynaptic mechanisms, or that another messenger is involved. Possible candidates for a putative early messenger include endothelial-derived relaxing factor (EDRF, nitric oxide) which is rapidly released from cerebellar neurons by NMDA (ref. 28). □

CLASSICAL T lymphocytes recognize foreign antigens in the context of self major histocompatibility complex (MHC) molecules by means of the T-cell receptor (TCR)$\alpha\beta$ heterodimer[1–3]. The genes for TCR β-chains, like immunoglobulin genes, are subject to allelic exclusion. The introduction of a functional TCR-β gene into the germline of mice prevents rearrangement of endogenous TCR-β genes[4]. Here we report that the introduction of a non-functional TCR-β gene with a deletion of the major part of the variable region (ΔV-TCR-β), also inhibits endogenous TCR-β gene rearrangement. This inhibition is mediated via the encoded protein because impairment of endogenous TCR-β gene rearrangement is not found if a frameshift mutation is introduced into the *DJ* region of the ΔV-TCR-β transgene. The ΔV-TCR-β transgene can lead to two phenotypes, in which lymphoid development is perturbed. Phenotype A is characterized by a severe impairment of both T and B cell development as reflected by the complete absence of certain lymphoid organs. In phenotype B, lymphoid organs are macroscopically normal, but T cell differentiation is impeded. Virtually all thymocytes lack membrane expression of TCR-$\alpha\beta$, but nevertheless carry the CD4 and CD8 antigens ($CD4^+CD8^+$ phenotype); they do not, however, mature further. The defect in mice of phenotype B but not of phenotype A can be corrected by the introduction of a functional TCR-β gene.

We investigated whether expression of a non-functional TCR-β gene inhibits endogenous TCR-β expression in transgenic mice. If so, the resulting mice would lack cells bearing functional TCR-$\alpha\beta$, which would be expected to influence the constellation of the immune system.

The relevant gene was isolated from a genomic library of the cytotoxic T cell clone B6.2.16 (ref. 4); this is specific for the male antigen HY and restricted by the H-$2D^b$ molecule, and was previously used for the construction of transgenic mice[4,5]. The cosmid clone cosHYβ9-1.14-5 contains a functionally rearranged TCR-β gene, consisting of the *V*β5.1 leader, *V*β8.2, *D*β2, *J*β2.3 and the *C*β2 gene segments. A 20-kilobase (kb) *KpnI* fragment derived from this clone was expressed at high levels in transgenic mice[5]. The non-functional gene was derived from this fragment by deletion of a 707-base pair (bp) *PstI* fragment, containing most of the *V* region and the complete *VDJ* junction. The reading frame and splice signals were restored by the insertion of two complementary synthetic oligonucleotides. The resulting 19.4-kb *KpnI* fragment (ΔV-TCR-β) encodes the Vβ5.1 leader, a 12-amino-acid sequence from the N-terminal Vβ8.2 region, the C-terminal Jβ2.3 region and the Cβ2 region (Fig. 1).

Four independent transgenic founders were obtained using the ΔV-TCR-β gene construct. The same construct gave rise to two different phenotypes, A and B (Table 1). Founders 1670, 1673 and 1733 exhibited phenotype A, whereas founder 1735 exhibited phenotype B. Offspring of founder 1673 were of either phenotype A or B. The A-phenotype offspring of founder 1673 had the same arrangement of the transgene as the founder, whereas B-phenotype offspring had lost a fraction of the transgenic copies. Founders 1733 and 1735 stably transmitted their transgenes.

Phenotype A is characterized by the complete absence of the thymus, lymph nodes and Peyer's patches in 8-week-old mice. In 5-month-old mice we occasionally observed a small thymus. Mice of phenotype A were highly sensitive to opportunistic infections. The transgene was highly expressed in the spleen of the A phenotype (Table 1). Immunofluorescence analysis demonstrated that in phenotype-A spleen, the percentage of T cells was greatly reduced from that of normal, as reflected by staining with the monoclonal antibodies anti-Thy1 (from 38% to 6%), anti-CD3 (from 38% to 13%), anti-CD4 (from 20% to 8%) and anti-CD8 (from 15% to 2.5%) (Fig. 2*a*). Splenic B cells defined by staining with anti-CD45R (B220) expressed normal levels of surface immunoglobulin, detected by fluorescein isothiocyanate (FITC)-conjugated goat anti-mouse immunoglobulin antibodies (data not shown). In serum of A-phenotype mice, levels of IgM slightly lower than normal were observed, whereas IgG2a was not detectable and the levels of other IgG isotypes were less than normal. The cellular composition of bone marrow of A-phenotype mice was also abnormal. The percentage of cells expressing the CD45R (B220) marker was lower than in control mice; cells uniformly expressed the CD44 marker (Pgp1) and the percentage of CD11b (Mac1)-positive cells was higher than normal (Fig. 2*b*). No expression of the transgene was detected in the bone marrow (Table 1). The aberrant phenotype A could not be corrected by crossing-in functional TCR-β or $\alpha\beta$ transgenes.

Thus, in A-phenotype mice, development not only of T cells, but also of B cells is severely impaired, resulting in gross disorders such as the complete absence of certain lymphoid organs. It is not clear whether the impairment of B cell development is

end α	−	ND	NP	−	−	+	+	−

Abbreviations end β, endogenous 1-3-kb TCR-β mRNA; end α, endogenous TCR-α mRNA, ND, not determined, <, strongly reduced

due to T cell deficiency (for example, lack of helper T cell subsets producing B cell growth factors or differentiation factors, or both) or if it is due to a direct effect of the expression of the transgene in B cells. The A phenotype was not observed in more than 25 independent transgenic lines that expressed a functional TCR-β gene; this phenotype must, therefore, be a result of specific features of the ΔV-TCR-β chain.

In B-phenotype mice, all lymphoid organs were macroscopically normal. In the thymus, the ΔV-TCR-β transgene was expressed at high levels, whereas the expression of the 1.3-kb mature messenger RNA for the endogenous TCR-β, but not the mRNA for TCR-α, was strongly suppressed (data not shown). In this respect thymocytes of B-phenotype mice resemble pre-B cells, in which heavy- but not light-chain expression is inhibited by the $D_\mu J_\mu C_\mu$ protein product of a partially rearranged heavy-chain gene[6]. In mice that carry a functional TCR-β transgene, suppression of endogenous TCR-β gene expression in the thymus appeared to be due to the incomplete rearrangement of the *VDJ* regions[4]. When DNA from thymocytes of B-phenotype mice was analysed by Southern blotting using a Dβ1 probe, a series of bands representing incomplete TCR-β gene rearrangements was detected (Fig. 3*a*). This suggests that introduction of the ΔV-TCR-β gene construct impairs TCR-β gene rearrangement according to a mechanism similar or identical to that involved when a TCR-β gene construct encoding a functional TCR-β chain is introduced.

The number of thymocytes in mice of phenotype B was normal. Thymocytes from B-phenotype mice and normal controls were stained with a panel of T cell-specific monoclonal antibodies (Fig. 3*b*). Whereas in normal mice ~15% of thymocytes expressed CD3 antigen at high levels (CD3-bright cells), in thymuses of B-phenotype mice only a small percentage (2–3%) of CD3-bright cells were detected. Similarly, whereas 85% of normal thymocytes expressed CD3 antigen at low levels (CD3-dull cells) or not at all (CD3-negative cells), the CD3-dull population was virtually absent in thymocytes from B-phenotype mice. The same observation was made for expression of TCR-$\alpha\beta$ (data not shown). Protein chemical analysis of thymocyte popu-

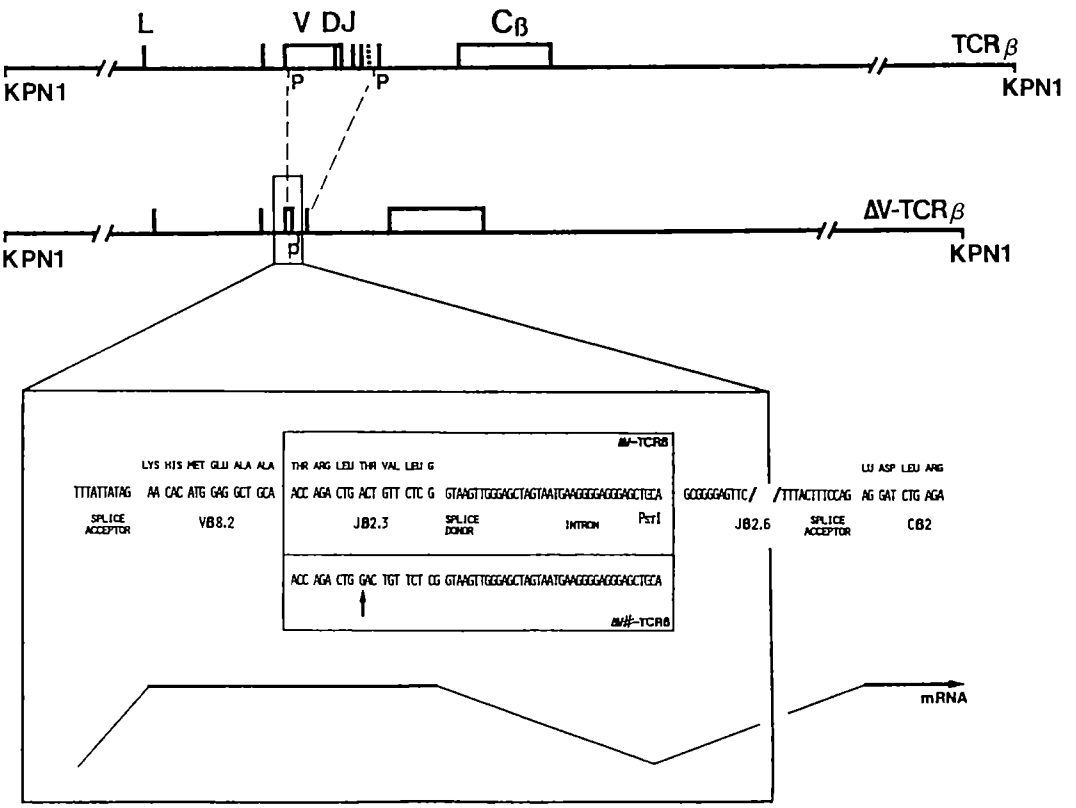

FIG. 1 Construction of the mutant TCR β-chain genes. The upper line illustrates the 20-kb *KpnI* fragment derived from the cosmid clone cosHYβ9 114-5 containing the functionally rearranged TCR-β gene expressed in the B6.2.16 clone. The second line shows the structure of the mutant TCR-β genes, present on 19 4 kb *KpnI* fragments used for injection. The region of interest is enlarged below to show in detail the region mutated in the ΔV-TCR-β constructs, the sequences inserted by the oligomers in the ΔV constructs are boxed and the additional nucleotide in the $\Delta V\#$-TCR-β construct is indicated by an arrow.

METHODS. The 20 kb *KpnI* fragment from cosHYβ9-1.14-5 was subcloned in pUC18, the functional TCR-β gene from B6.2 16 contains, in addition to the fused *V*β8.2, *D*β2.3 and *J*β2 segments, the *J* segments *J*β2.4, *J*β2.5, ψ*J*β2 and *J*β2 6; a 4.0-kb *XbaI* fragment containing the *VDJ* join and the remaining *J* segments was inserted into pSP64; in this fragment three *PstI* sites (P) are present, the first at 17 bp from the start of the *V*β8.2 segment, the second between the *J*β2.5 and the ψ*J*β2 segments and the third 22 bp after the ψ*J*β2 segment; the 707 bp between the first and third *PstI* site were deleted from the *XbaI* fragment; two complementary oligonucleotides were synthesized (Millipore Cyclone) corresponding to the last six codons of the *J*β2 3 segment and the 34 bp downstream region from this segment, including the splice donor sequences. These were inserted in the *PstI* site and replaced the 707-bp *PstI* fragment, the sequence was chosen such that annealed oligomers carried a *PstI* overhang at the borders, but correct insertion only restored the 3′ *PstI* site; by means of several subcloning steps, the annealed oligomers were introduced into the *XbaI* fragment, which was inserted into the large *KpnI* fragment present in PUC18; all manipulations involving the mutation of the *VDJ* region were checked by nucleotide sequence analysis. For injection, the DNA inserts were released from the vector by *KpnI* digestion and purified as described[5] and transgenic (CBA/BR × C57Bl/LiA) F_2 mice were generated by the pronuclear injection technique; transgenic founders were backcrossed with C57Bl/LiA (H-2^{be}) mice; screening by Southern blotting of tail DNA using a *J*β2-specific probe as described[5]; the *J*β2-specific probe recognizes a 2.6-kp *Eco*RV fragment in germline DNA, whereas an 11 kb *Eco*RV fragment is diagnostic for the ΔV constructs.

lations depleted of CD3-bright cells confirmed the absence of a TCR-CD3 complex at the cell surface (data not shown). Despite the lack of TCR-$\alpha\beta$, the thymocytes uniformly expressed both CD4 and CD8 antigens (Fig. 3*b*). The very small population of CD3-bright cells appeared to comprise $CD4^+CD8^-$, $CD4^-CD8^+$ as well as $CD4^-CD8^-$ cells.

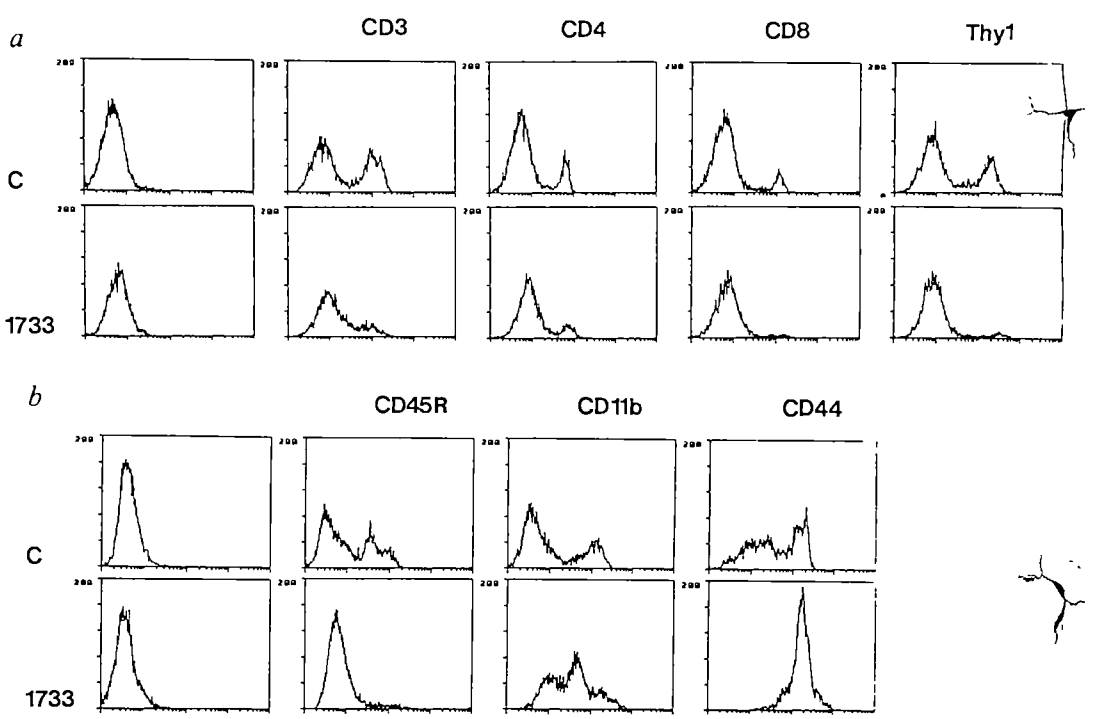
In the spleen of 8-week-old B-phenotype mice, the percentage of T cells was reduced by about twofold compared with control mice, as reflected by staining with the monoclonal antibodies anti-CD3 (from 41% to 23%), anti-CD4 (from 24% to 11%) and anti-CD8 (from 15% to 8%). By 6 months of age, the percentage of T cells had reached normal levels. Purified splenic T cells stained normally with anti-CD3, anti-CD4 and anti-CD8 antibodies, as well as with antibodies specific for the TCR-V-β8 region (F23.1)[7] and a common determinant on TCR-$\alpha\beta$[11] (data not shown). In purified T cells from the spleen, transcription of the transgene and also of endogenous TCR-β and α genes occurred (Table 1). Apparently, in these T cells, expression of the transgene has not inhibited endogenous TCR-β gene rearrangement. The marker profile of B-phenotype bone marrow was normal (not shown).

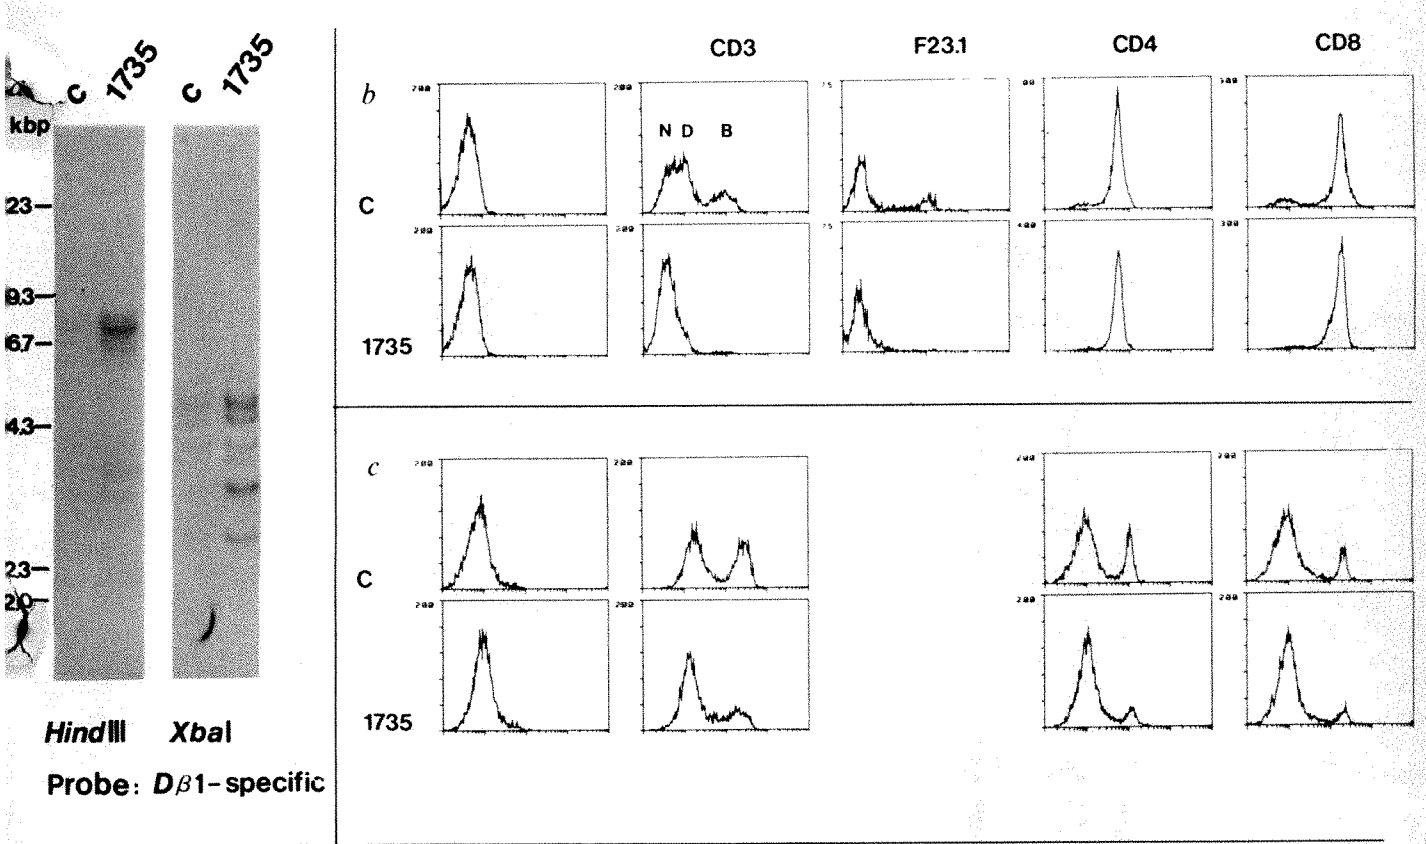
To investigate whether the mRNA of ΔV-TCR-β or the polypeptide encoded by ΔV-TCR-β caused inhibition of endogenous TCR-β gene rearrangement, resulting in the observed reduction of mature CD3 antigen-expressing cells in mice of both phenotypes, a $\Delta V\#$-TCR-β clone was constructed that carried an additional nucleotide in the region of the synthetic oligomers (Fig. 1). In this clone the $C\beta$ segment is no longer in frame with the AUG initiation codon. Two transgenic founders were obtained with this construct. Thymus, spleen and lymph nodes were normal (macroscopically, with respect to numbers of B and T cells, and as judged by immunofluorescence analysis with specific antibodies). The $\Delta V\#$-TCR-β transgene, but also endogenous TCR-β genes were transcribed at high levels in these mice (data not shown), indicating that the mRNA of $\Delta V\#$-TCR-β by itself is stable but unable to inhibit endogenous TCR-β gene rearrangement. This strongly suggests that inhibition of the endogenous TCR-β gene rearrangement is mediated by the protein encoded by the ΔV-TCR-β transgene.

We conclude that in B-phenotype mice, differentiation of TCR-$\alpha\beta$ cells is impaired owing to the absence of TCR-$\alpha\beta$ protein on the plasma membrane of thymocytes. In the vast majority of B-phenotype thymocytes, endogenous TCR-β protein is not synthesized, because the transgene inhibits endogenous TCR-β gene rearrangements. Consequently, thymocytes do not mature to the single positive stage because of the lack of positive selection in the absence of a functional TCR $\alpha\beta$ at the cell surface[8–10]. Because the generation of mature T cells is significantly impeded, spleens of B-phenotype young mice contain fewer T cells than those of normal young mice. The T cells that do reach the spleen have escaped inhibition of TCR-β rearrangement and do express a functional TCR-$\alpha\beta$. These cells probably originate from the few CD3-bright cells seen in the thymus. It has not yet been investigated whether the $TCR\gamma\delta^+$ population is affected in B-phenotype mice, but clearly no major expansion of this subset has occurred. This would have resulted in a discrepancy in reactivity with anti-CD3 and anti-TCR$\alpha\beta$ antibodies.

To confirm that the impairment of thymocyte maturation in B-phenotype mice was indeed caused by the absence of a functional TCR β-chain, these mice were crossed with transgenic mice carrying a functional TCR-β gene (strain 101, expressing the cosHYβ9-1.14-5 construct[5]). Figure 3*d* shows the immunofluorescence data obtained with thymocytes from the double transgenic offspring. Clearly, the CD3-bright thymocyte population has been restored, and it also expresses TCR $\alpha\beta$ heterodimer. This receptor is composed of the products of the functional TCR-β transgene and endogenous TCR α-chains as demonstrated by its reactivity with Vβ8-specific antibody F23.1[7]. Expression patterns of antigens CD4 and CD8 were indistinguishable from those of the 101 line. Apparently, expression of TCR $\alpha\beta$-CD3 at the plasma membrane restores differentiation of thymocytes, yielding mice of the $CD4^+CD8^-$ and $CD4^-CD8^+$ mature thymocyte subsets. Spleens of these mice contained normal numbers of T cells, all of which stained with F23.1 antibody (Fig. 3*e*) and expressed both transgenes (data not shown).

By using TCR $\alpha\beta$-transgenic severe combined immunodeficiency (SCID) mice, Scott *et al.*[12] have recently shown that the transition of $CD4^-CD8^-$ thymocytes to double positive $CD4^+CD8^+$ thymocytes requires the productive rearrangement of TCR gene segments. Here we have shown that cell-surface





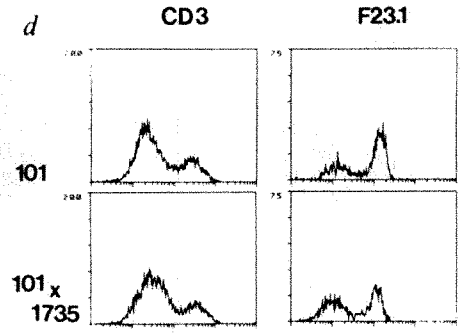


FIG 2. FACS analysis of splenocytes (*a*) and bone-marrow cells (*b*) from 8-week-old non-transgenic control (C) and phenotype-A mice (strain 1733). Horizontal axis, staining intensity; Vertical axis, number of cells. Antibodies used. FITC-conjugated mouse anti-rat kappa-chain mAb (−); 145-2C11[13] (anti-CD3); H129-19[14] (anti-CD4); 53-6 7[15] (anti-CD8), 59AD2 2 (anti-Thy1); RA3-6B2[16] (anti-CD45R); MI/70 15[17] (anti-CD11b); and Pgp1[18] (anti-CD44)
METHODS. Single-cell suspensions were prepared from spleen (*a*) or bone marrow (*b*), erythrocytes were lysed, washed in PBS containing 0 5% w/v BSA and 0 05% sodium azide, counted, and incubated with saturating amounts of antibodies and then stained with FITC-conjugated mouse anti-rat kappa-chain mAb or stained directly with FITC-conjugated 145-2C11 (anti-CD3) mAb; cells were washed three times and analysed using a FACScan (Becton Dickinson) flow cytometer, 5,000 viable cells were analysed in each sample

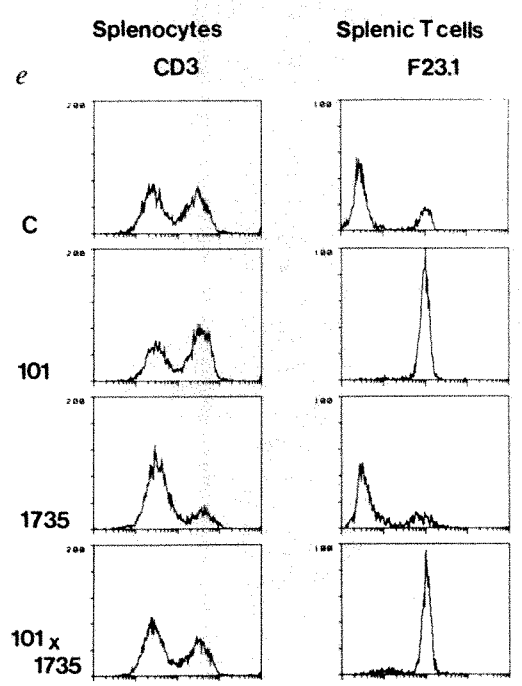

FIG. 3 Characterization of B-phenotype mice. *a*, Southern-blot analysis of DNA isolated from thymocytes from phenotype-B mice (strain 1735) using the *Dβ*1-specific probe showing partial rearrangement of endogenous TCR-*β* genes; the *Dβ*1-specific probe is a 1.4-kb *PstI* fragment located 1.25 kb upstream of the *Dβ*1 segment[4]. *b*, *c*, Staining of thymocytes (*b*) and splenocytes (*c*) from 8-week-old controls (C) and B-phenotype mice (strain 1735). Antibodies used: 145–2C11 (anti-CD3), F23.1 (anti-V*β*8), H129.19 (anti-CD4) and 53–6.7 (anti-CD8). N, CD3 negative; D, CD3-dull; B, CD3 bright. *d*, *e*, Restoration of T-cell maturation in Δ*V*-TCR-*β* mice by functional TCR-*β* transgene. Staining of thymocytes (*d*) and total splenocytes and purified T cells from spleen (*e*) from 8-week-old mice with anti-CD3 and F23.1 antibodies. Mice of strain 101 (carrying the cosHY*β*9-1.14-5 transgene) and strain 1735 were crossed to generate transgenic mice carrying either only the complete functional TCR-*β* transgene (101) or both transgenes (1735 × 101).

METHODS. For Southern-blot analysis, 8 μg total genomic DNA was digested with restriction endonucleases, separated on agarose gels and transferred to nitrocellulose; filters were hybridized to ^{32}P-labelled probes as described[5]. Mice were screened by tail-DNA analysis using the *Jβ*2-specific probe; this probe recognizes a 2.6-kb fragment in germ-line DNA, whereas a 2.3-kb fragment and a 11-kb fragment are diagnostic for the functional TCR-*β* transgene and the Δ*V-TCR-β* transgene, respectively; purified T cells were isolated by depletion of B cells; splenocytes were incubated with magnetic beads coated with goat anti-mouse immunoglobulin antibody (Dynal, Norway) for 1 h at 4 °C and the rosetted B cells were removed with a magnet. Preparation of cell suspensions and FACS analyses were performed as described in the legend to Fig. 2; cells were incubated with H129.19 (anti-CD4) and 53.6.7 (anti-CD8) mAbs and stained with FITC-conjugated mouse anti-rat kappa-chain mAb, or with F23.1 and stained with FITC-conjugated goat anti-mouse immunoglobulin (Tago), or stained directly with FITC-conjugated 145–2C11 (anti-CD3) antibody.

expression of functionally rearranged TCR-$\alpha\beta$ is not required for the induction of the expression of CD4 and CD8 antigens. It remains to be shown whether the intracellular expression of defective TCR-β and endogenous TCR-α is required for T cell development to advance to the double positive stage. □

Selective development of CD4$^+$ T cells in transgenic mice expressing a class II MHC-restricted antigen receptor

T LYMPHOCYTES are predisposed to recognition of foreign protein fragments bound to cell-surface molecules encoded by the major histocompatibility complex (MHC)[1,2]. There is now compelling evidence that this specificity is a consequence of a selection process operating on developing T lymphocytes in the thymus[3–6]. As a result of this positive selection, thymocytes that express antigen receptors with a threshold affinity for self MHC-encoded glycoproteins preferentially emigrate from the thymus and seed peripheral lymphoid organs. The specificity for both foreign antigen and MHC molecules is imparted by the α and β chains of the T-cell antigen receptor (TCR)[7,8]. Two other T-cell surface proteins, CD4 and CD8, which bind non-polymorphic regions of class II and class I MHC molecules respectively[9,10], are also involved in these recognition events and play an integral role in thymic selection. In order to elucidate the developmental pathways of class II MHC-restricted T cells in relation to these essential accessory molecules, we have produced TCR-transgenic mice expressing a receptor specific for a fragment of pigeon cytochrome c and the E^k (class II MHC) molecule. The transgenic TCR is expressed on virtually all T cells in mice expressing E^k. The thymuses of these mice contain an abnormally high percentage of mature CD4$^+$CD8$^-$ cells. In addition, the peripheral T-cell population is almost exclusively CD4$^+$, demonstrating that the MHC specificity of the TCR determines the phenotype of T cells during selection in the thymus.

A large number of cell surface proteins have now been identified which function in the cellular interactions of T lymphocytes. Central among these is the antigen receptor, which enables T cells to detect foreign peptides bound to MHC proteins on the surface of other cells. The major population of T lymphocytes express antigen receptors comprised of disulphide bonded α and β chains noncovalently associated with four or five other polypeptide chains of the CD3 complex (reviewed in ref. 11). T cells bearing $\alpha\beta$ TCR can be divided into two subsets, based on their specificity for class I or class II MHC proteins. The CD4 and CD8 molecules, expressed on cells specific for class II or class I MHC molecules respectively, also delineate these T-cell subsets[12]. These MHC-binding molecules are thought to associate with the $\alpha\beta$ TCR, enhancing the avidity of cell to cell interactions as well as playing a role in T-cell activation[13–15]. Peripheral T cells arise from thymic CD4$^+$CD8$^+$ precursors, so called double positive cells[16,17]. As a given T cell undergoes thymic maturation, one of these cell surface proteins is downregulated resulting in a CD4$^+$CD8$^-$ or CD4$^-$CD8$^+$ phenotype. By an unknown mechanism the differentiation of thymocytes to these phenotypes is intimately linked to the positive selection of T cells expressing class I or class II MHC specific receptors. One approach to understanding these developmental mechanisms is the use of TCR transgenic mice which possess an extremely limited TCR repertoire. Recent reports which described transgenic mice expressing $\alpha\beta$ receptors specific for class I MHC gene products[18,19] have shown that peripheral T cells bearing the transgene-encoded receptor were highly skewed toward expression of CD8. In this report, we examine the development of the other major subpopulation of T cells, those restricted to class II MHC proteins, utilizing mice transgenic for an E^k restricted TCR.

(C57B16/J × SJL/J)F_2 transgenic mice were produced by co-microinjection of the α and β TCR gene constructs shown in Fig. 1. Both transgenes contained endogenous promoter and enhancer sequences, although the position of the β-chain enhancer was altered as was the original V_α–C_α distance. The productively rearranged α chain gene (V_α 11.1–J_α84) was derived from the T-cell clone AN6.2 (ref. 20) while the β chain gene (V_β3–J_β1.2) was derived from T cell clone 5C.C7 (ref. 21). Both these T-cell lines are specific for the carboxy-terminal fragment of pigeon cytochrome *c* and the E^k molecule, although they exhibit

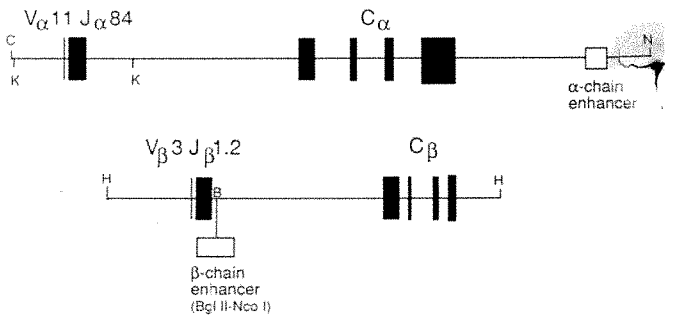

FIG. 1 TCR transgenes. A genomic clone containing a productively rearranged V_α–J_α gene derived from T-cell clone AN6.2 (ref. 20) was a generous gift from A. Winoto (Whitehead Institute). A 6.6-kilobase (kb) *Sal* I fragment containing the V_α–J_α was subcloned into the plasmid vector pBS (Stratagene) and a 3.3 kb fragment was isolated utilizing a *Kpn* I site 1.2 kb 5′ to the V and a 3′ *Kpn* I site in the multiple cloning site. This fragment was cloned into the *Kpn* I site of a pBS-based plasmid (modified with a 5′*Cla*I site and a 3′*Not* I site) containing the complete genomic C_α gene[25] including the recently identified enhancer sequence[26], kindly provided by M. Davis (Stanford University). The rearranged genomic β chain gene derived from T-cell clone 5C.C7 (ref. 21) was isolated as previously described[27], and a 913 base pair *Bgl* II–*Nco* I fragment containing the β chain enhancer[28] was cloned into the J–C intron at the *Bam* HI site with a *Bgl* II linker. The 15.2 kb *Cla* I–*Not* I fragment containing the complete α-chain gene and the 9.8 kb *Hin*dIII fragment containing the complete β-chain gene were microinjected in equimolar amounts by standard procedures[29].

fine specificity differences between them. This particular α and β TCR pair has been expressed *in vitro* by gene transfer and the resulting transfectants maintain specificity for pigeon cytochrome c and E^k (J.K., unpublished data). In fact, this TCR differs from one found in a naturally occurring pigeon cytochrome c specific T cell by only a single amino acid in the V-J junction of the α-chain (clone AD10 in ref. 22).

Of 56 mice produced, 14 were found to have incorporated both α and β transgenes into their genome. Results from the progeny of one male founder mouse possessing approximately 2 copies of the α transgene and 1 copy of the β transgene are presented here. This founder mouse was mated to a B10.A mouse and the offspring were H-2 typed using anti-H-2K monoclonal antibodies. The results from $(H\text{-}2^b \times H\text{-}2^a)F_1$ progeny which express A^k, A^b, E^k and E^b class II MHC proteins are discussed below. Cell yields of thymocytes, lymph node cells and spleen cells were similar from transgenic and normal mice. The thymocytes from a 6 week-old transgenic mouse and a normal littermate were stained for CD3, or CD4 and CD8 and analysed by flow cytometry (Fig. 2*a*). In the normal mouse three populations of TCR bearing cells can be distinguished, as determined by expression of CD3. Approximately 25% of total thymocytes

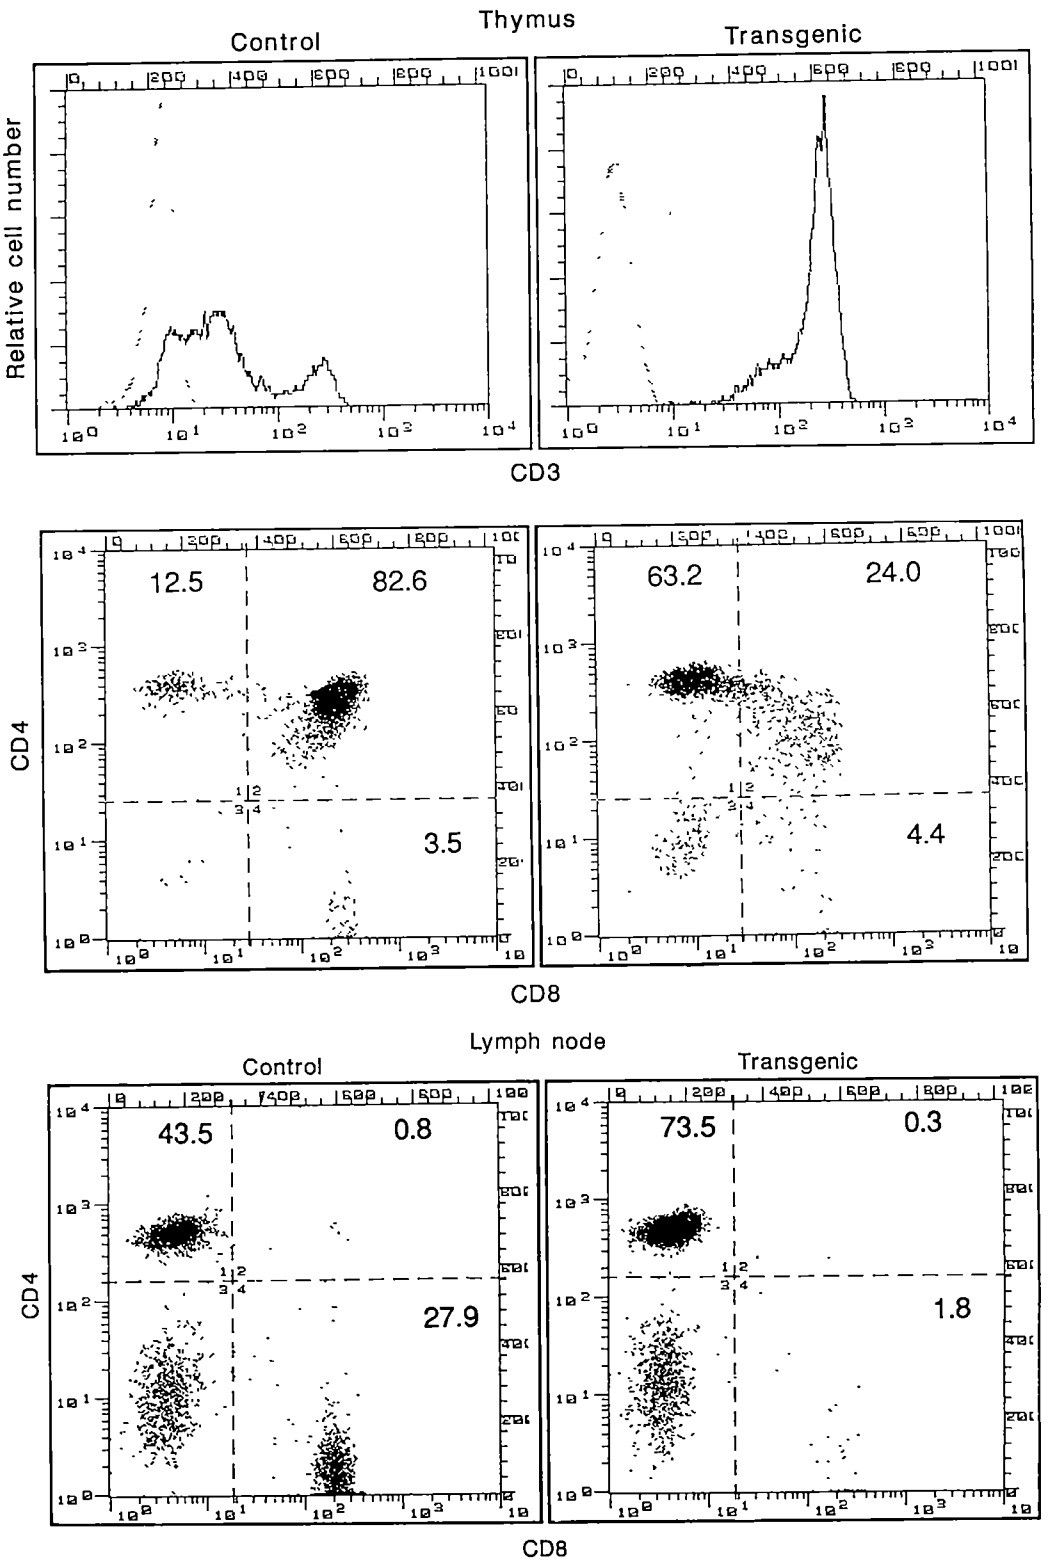

FIG 2 Phenotype of T cells in normal and $\alpha\beta$ transgenic mice. *a*, (Upper panels) thymocytes from a 6-week-old $\alpha\beta$ transgenic mouse or a normal littermate were stained with the anti-CD3 monoclonal antibody 2C11 (ref. 30) followed by FITC-conjugated goat anti-hamster Ig (Caltag) (solid line). Control staining was with secondary antibody alone (broken line). Cells were analysed on a FACScan flow cytometer (Becton Dickinson) using FACScan Research Software. Dead cells were eliminated from the analysis on the basis of forward and sideways light scatter. Each plot represents the results from 5,000 viable cells (Lower panels), thymocytes were stained with a mixture of PE conjugated anti-CD4 and FITC conjugated anti-CD8 (Becton Dickinson) Cells were analysed as above The percentage of total cells in each quadrant is indicated *b*, Lymph node cells were stained with anti-CD4 and anti-CD8 as described above

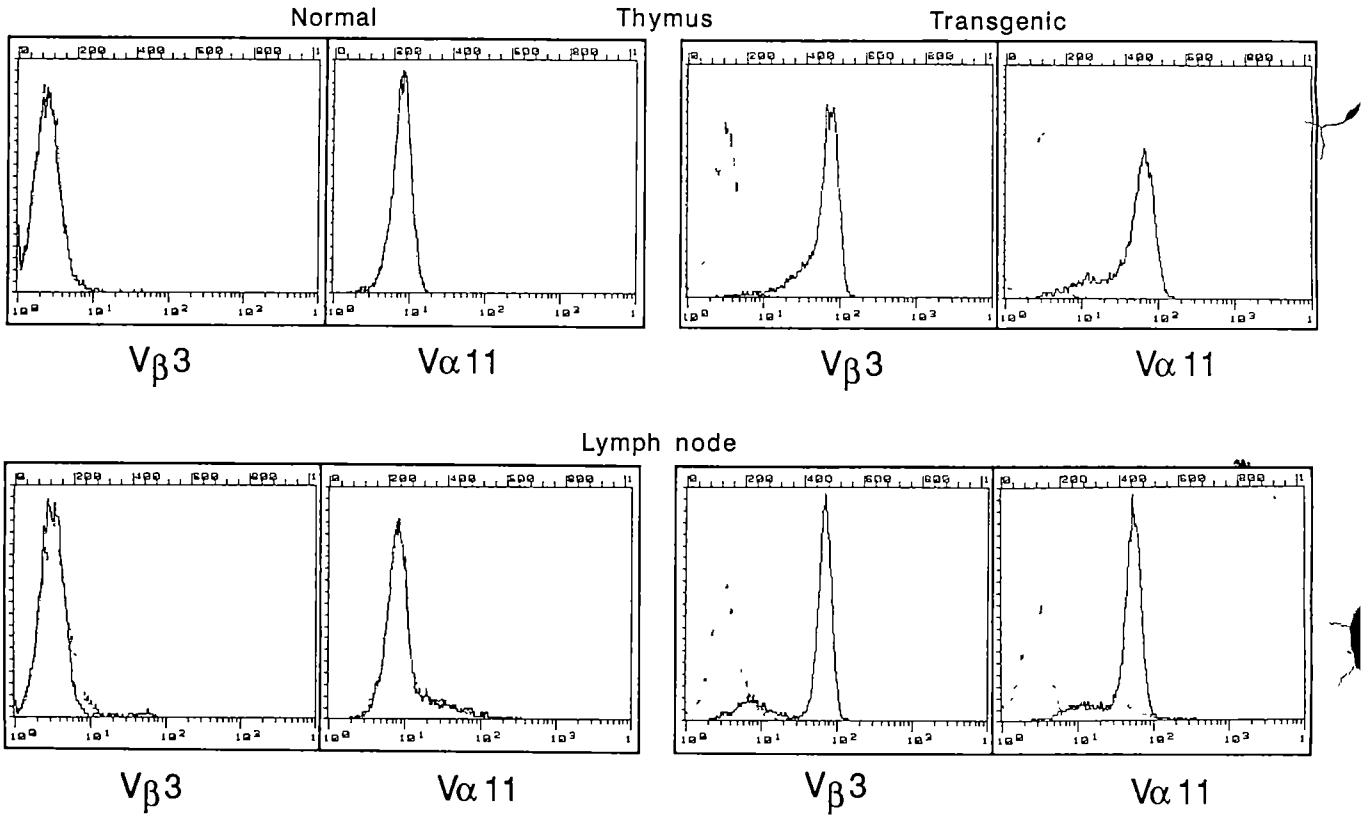

FIG. 3 Expression of $\alpha\beta$ transgenes in thymus and lymph node Thymocytes or lymph node cells from a transgenic or normal littermate mouse were stained with FITC-conjugated anti-$V_\beta 3$ monoclonal antibody KJ25 (ref 24) (solid line) or FITC-conjugated normal rat Ig (broken line) as a control. Alternatively, cells were stained with the hamster anti-$V_\alpha 11$ monoclonal antibody 1F2 followed by FITC-conjugated goat anti-hamster Ig (Caltag) (solid line) Controls for these stainings were with secondary reagent alone (broken lines) Cells were analysed as described in Fig 2.

express no detectable CD3, 57% express low levels and a small population (18%) expresses high levels of CD3 (Fig. 2*a*). This progression of TCR expression from low to high is a component of normal thymocyte maturation[23]. In sharp contrast, thymocytes from transgenic mice (Fig. 2*a*) are 99% $CD3^+$, 75% of these staining brightly and 25% somewhat duller. Unlike normal thymocytes, therefore, the TCR in these transgenic mice is expressed throughout thymocyte development, although there is a modulation of expression level as in normal mice. Similar observations have been reported for other $\alpha\beta$ transgenic mice[18]. The fact that TCR transgenes do not have to undergo the process of V–J rearrangement as do endogenous TCR genes may result in their accelerated expression.

The CD4/CD8 phenotypes are also altered in the transgenic mice, which express a higher than normal percentage of $CD4^+CD8^-$ thymocytes (63% compared with 13%) and a lower than normal percentage of double positive cells (24% compared with 83%) (Fig. 2*a*). Although the $CD4^-CD8^+$ populations in normal and transgenic mice appear similar as presented in Fig. 2*a*, a more stringent gating to eliminate potential $CD4^{low}CD8^+$ cells suggests that there is also a twofold reduction in CD8 single positive cells. An increase in double negative cells is also found in the transgenic thymus (Fig. 2*a*), although the significance of this observation is unclear. Both the CD3 profile and the CD4/CD8 phenotyping are consistent with the presence of a larger than normal fraction of mature thymocytes in these $\alpha\beta$ transgenic mice. In addition, the mature thymocytes are greatly skewed towards expression of CD4. The steady state decrease in the size of the double positive population and the corresponding increase in CD4 single positive cells is consistent with the presence of a positive selection process that is more efficient than normal. The fact that the vast majority of T cells in this mouse expresses the transgenic TCR (see below) supports this idea. Unlike a normal mouse, where positive and negative selection of cells bearing random TCR's presumably eliminate many potential T cells, the selection of these transgenic thymocytes would not be so constrained.

The strong bias for $CD4^+$ cells found in the transgenic thymus is also apparent in an analysis of peripheral T cells. As shown in Fig. 2*b*, lymph node cells from the transgenic mice are severely depleted of $CD8^+$ cells. Most, if not all, of the few $CD8^+$ T cells express $V_\beta 3$ (not shown). Whether these cells express endogenous TCR as well is not known. The expression of endogenous TCR in these transgenic mice has not been deter-

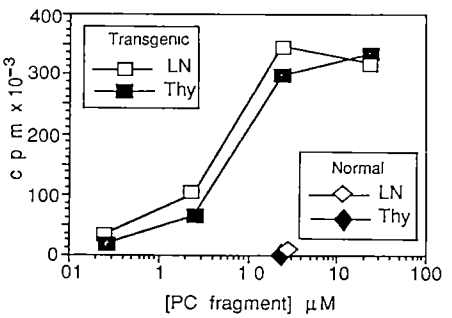

FIG 4 Primary response of normal and $\alpha\beta$ transgenic cells to pigeon cytochrome *c* fragment 5×10^4 thymocytes (closed symbols) or lymph node cells (open symbols) from a transgenic (boxes) or normal (diamonds) mouse were cultured in 96 well flat bottom tissue culture plates in the presence of 3×10^5 mitomycin-c treated autologous spleen cells and various concentrations of a synthetic carboxy-terminal fragment of pigeon cytochrome c, residues 88–104 After 48 h, cultures were pulsed with 1 μCi [^{3}H] thymidine and harvested after an additional 16 h incubation. Data represent mean c.p.m [^{3}H] thymidine incorporation of triplicate cultures. In the absence of pigeon cytochrome-*c* fragment all cultures showed a mean [^{3}H]thymidine incorporation of <400 c p.m.

mined directly. If many of the transgenic TCR bearing cells also expressed random endogenous TCR on their surface, however, we would not have expected to see such a striking enrichment for $CD4^+$ T cells.

In order to assess α and β transgene expression, thymocytes were stained with an anti-$V_\beta 3$ monoclonal antibody KJ25 (ref. 24) and an anti-$V_\alpha 11$ monoclonal antibody 1F2 (S.J. & N.R.J.G., manuscript in preparation). This anti-$V_\alpha 11$ antibody binds T cells expressing $V_\alpha 11.1$-$J_\alpha 84$ and $V_\alpha 11.2$-$J_\alpha 2B4$ but its reactivity against other V_α 11 family members and other $V_\alpha 11$-J_α combinations is unknown. As shown in Fig. 3, expression of $V_\beta 3$ or $V_\alpha 11$ in thymocytes of normal mice of these particular strains is low (3.7% and <0.5% respectively). In a transgenic littermate, however, 97% of thymocytes expressed $V_\beta 3$ and 94% expressed $V_\alpha 11$ (Fig. 3). Similar to the finding with anti-CD3 (Fig. 1) approximately 80% of cells stained brightly with these reagents while 20% stained less brightly.

Because the mice analysed here express E^k, it is expected that cells bearing the transgenic TCR would be positively selected in the thymus and appear in the periphery. This is indeed the case. Less than 2% of lymph node cells from the normal mouse control express $V_\beta 3$, and $V_\alpha 11$ expression was undetectable on these cells (Fig. 3). Conversely, 78% of lymph node cells from the transgenic mouse expressed $V_\beta 3$ and 73% expressed $V_\alpha 11$ (Fig. 3). Given that these lymph nodes contained similar numbers of $CD3^+$ cells (not shown), we conclude that virtually all the T cells in these mice express the cytochrome c specific TCR. In order to test this point and to assess whether the transgenic T cells were functional, we assayed for primary responses to a synthetic fragment of pigeon cytochrome c using autologous spleen cells as a source of antigen presenting cells. As shown in Fig. 4, both thymocytes and lymph node cells gave potent primary respones to the pigeon cytochrome c fragment. There was no detectable response from normal cells. The fact that the transgenic thymocytes were as responsive as peripheral T cells, in the absence of added factors, demonstrates that a large number were functionally, as well as phenotypically, mature.

The $\alpha\beta$ transgenic mice described in this report appear to be almost monoclonal in T-cell antigen specificity as well as CD4 phenotype. Surprisingly, the mice appear quite healthy. It remains to be determined whether these mice are indeed anergic to other antigens and environmental pathogens, and whether there are changes when the mice age. The changes noted in the thymus and periphery of these mice strongly support a positive selection process occurring during T-cell differentiation, linked to downregulation of CD8. It is not clear, however, whether the interaction of MHC and the receptor induces CD8 modulation or whether positive selection operates on transient randomly produced single positive populations. Finally, experiments to directly demonstrate the specificity for class II MHC molecules during positive selection in this system are in progress. □

Peptide-dependent recognition of H-2K^b by alloreactive cytotoxic T lymphocytes

William R. Heath, Melissa E. Hurd, Francis R. Carbone & Linda A. Sherman

Department of Immunology, Scripps Clinic and Research Foundation, La Jolla, California 92037, USA

ANTIGEN-specific T lymphocytes appear to recognize foreign antigens in the form of peptide fragments presented within the antigen-binding groove of class I or class II molecules encoded by the major histocompatibility complex (MHC). Alloreactive T cells also show specificity for MHC molecules, and various reports suggest that residues of the MHC molecules constitute at least part of the ligand to which alloreactive T-cell receptors bind[1–4]. The X-ray crystal structure of the human MHC class I molecule, HLA-A2[5], has provided evidence to strengthen the argument that MHC-bound self-peptide[6] might also contribute to such recognition[7]. We now provide direct evidence for this, showing that at least some alloreactive cytotoxic T lymphocyte clones recognize peptide fragments derived from cytoplasmic proteins. We reasoned that if self-peptides were involved in allorecognition, then the sequence of some of these peptides could vary between species, resulting in species-restricted distribution of the relevant ligand (s)[8–11]. Several alloreactive cytotoxic T lymphocyte clones specific for H–2K^b, expressed by the murine cell line EL4, did not lyse a human-cell transfectant expressing the H–2K^b molecule (Jurkat-K^b cells). However, these clones were able to lyse Jurkat-K^b cells sensitized by preincubation with an EL4 cytoplasmic extract cleaved by cyanogen bromide. The sensitizing activity from this extract was destroyed by protease and appeared to be due to a peptide consisting of 10 to 15 amino acids.

To identify species-restricted recognition of allogeneic MHC molecules, eleven H-2K^b-specific alloreactive cytotoxic T lymphocyte (CTL) clones were tested for their capacity to recognize H-2K^b (K^b) expressed by the murine cell line EL4, but not by transfectants of the human cell line Jurkat. Three clones that expressed this specificity (EL4-K^b-specific) were identified. All three clones were isolated from the same responder, expressed the $V_\beta 8$ segment of the T-cell antigen receptor, and showed similar target specificity, which indicated that they were probably sister clones. The target specificity of a representative EL4-K^b-specific clone (clone 35) is shown in Table 1 (experiment 1). Clone 52 is a representative cross-species reactive clone that was able to lyse both EL4 and Jurkat-K^b cells.

The specificity of the EL4-K^b-specific clones was determined by their ability to lyse the K^b-bearing cell lines C57BL/6.SV40 and B10.A(5R).SV40, but not the H-2^d cell line B10.D2,SV40 (Table 1, experiment 2). The specificity of the clones for K^b was further supported by their ability to release serine esterase in

TABLE 1 Target-cell specificity of K^b-specific alloreactive CTL clones

An EL4-K^b-specific CTL clone (clone 35) and a cross-species reactive K^b-specific CTL clone (clone 52) were analysed in several experiments for their capacity to lyse various K^b-expressing target cells. Target cells were labelled with ^{51}Cr and specific lysis was measured in a 4-h ^{51}Cr-release assay performed as previously described[17]. EL4 is a thymoma of C57BL/6 origin. Jurkat-K^b cells and Jurkat-A2/K^b cells refer to the human cell line Jurkat, transfected as previously described[18] with either a plasmid constructed by transfer of an *Eco*R1 fragment containing the *H-2K*^{b} gene[19] into pSV2neo, or with a plasmid containing an irrelevant chimaeric class I gene, *HLA-A2/K*^{b}, which encodes the α1 and α2 domains of HLA-A2 and the α3, transmembrane and cytoplasmic regions of K^b (ref. 18). Cell line R8 is derived from an Abelson leukaemia virus-transformed lymphosarcoma of (BALB/c × C57BL/6)F_1 origin[20]. LB27.4 cells were produced by fusion of the BALB/c lymphoma A20.2J with T cell-depleted C57BL/10 spleen cells[21]. MC57 cells were derived from a C57BL/6 fibrosarcoma induced by 3-methylcholanthrene[22]. Various SV40-transformed cell lines were derived from spleen cell populations[23]. Concanavalin A blasts were produced by stimulation of spleen cells (10^6 ml^{-1}) with concanavalin A (2.5 μg ml^{-1}) for 3 days at 37 °C. Lipopolysaccharide blasts and thioglycollate-elicited peritoneal exudate cells were produced as previously described[24,26]. EL4-K^b-specific CTL clones 6, 11 and 35 were derived from a (B10.D2 × B10.BR)F_1 mouse 10 days after priming with 2×10^7 EL4 cells. Cells were cloned by limiting dilution using irradiated B10.A(5R) (K^b, D^d, L^d) spleen-cell stimulators[13]. Cross-species reactive clones 52 and M37 were derived by limiting-dilution cloning of spleen cells from a naive or EL4 cell-primed B10.BR responder, respectively. CTL clones were maintained by weekly passage with irradiated C57BL/6 spleen-cell stimulators (3×10^6 ml^{-1}) in RPMI 1640 medium supplemented with 10% FCS, 2 mM L-glutamine, 50 μg ml^{-1} gentamicin, 50 μM 2-mercaptoethanol and 10% concanavalin A-stimulated rat spleen-cell supernatant[26]. The effector-to-target ratios in each experiment were as follows: (1) Clone 35, 10.1; clone 52, 10.1. (2) Clone 35, 12.1; clone 52, 9·1. (3) Clone 35, 10.1, clone 52, 10.1. (4) Clone 35, 6·1; clone 52, 3·1. (5) Clone 35, 8.1; clone 52, 8.1. (6) Clone 35, 13·1; clone 52, 14.1.

response to affinity-purified K^b molecules (derived from EL4 cells) immobilized on a solid support[13].

In an attempt to identify peptide antigen(s) that may be required for recognition of K^b by EL4-K^b-specific CTLs, a cytoplasmic extract was prepared from EL4 cells and subjected to cleavage by cyanogen bromide (CNBr). Jurkat-K^b cells were incubated with the CNBr-cleaved extract during ^{51}Cr-labelling and examined for their susceptibility to lysis by the EL4-K^b-specific CTL clones 6, 11 and 35, and two cross-species reactive clones, 52 and M37 (Fig. 1, panels *a–e*). By contrast with clones 52 and M37, which lysed Jurkat-K^b-cells under all conditions, the EL4-K^b-specific clones gave significant lysis of Jurkat-K^b cells exposed to CNBr-cleaved EL4-cell cytoplasm, but did not lyse cells exposed to uncleaved extract or to medium alone. Control Jurkat cells that were transfected with an irrelevant class I molecule, A2/K^b, were not sensitized by the CNBr-cleaved EL4-cell extract (Fig. 1, panels *f–j*).

The simplest explanation of these results is that the CNBr-cleaved EL4-cell extract contains specific peptide antigen(s) that are required for recognition of K^b by EL4-K^b-specific CTL clones. Another possibility, however, is that the EL4-K^b-specific CTL clones have a low affinity for K^b, and that the exposure

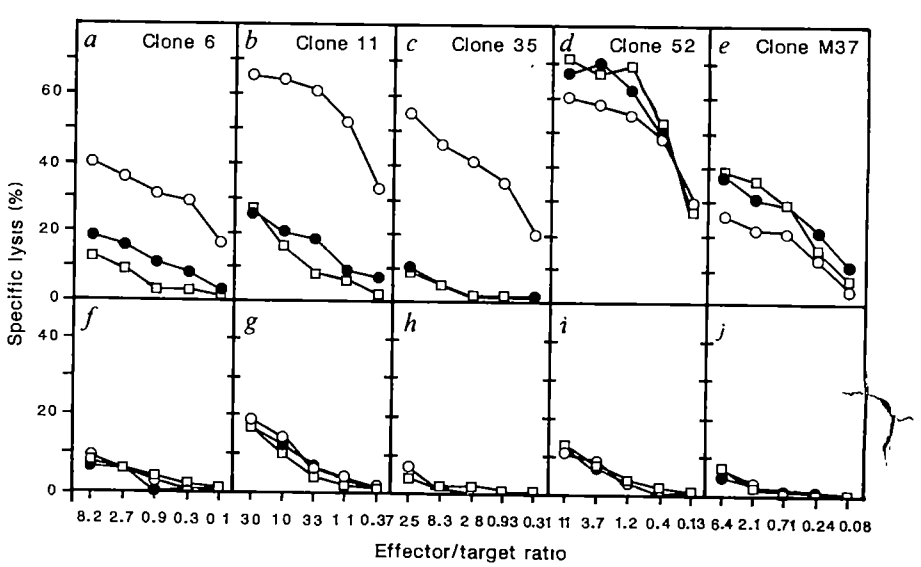

FIG 1 Susceptibility of Jurkat-K^b target cells to lysis after sensitization with a CNBr-cleaved EL4-cell cytoplasmic extract. Jurkat-K^b cells (10^6) (panels *a–e*), or Jurkat-A2/K^b cells (10^6) (panels *f–j*) were incubated with 0.3 ml ^{51}Cr (300 μCi) alone (●) or with 150 μg (200 μl) uncleaved (□) or CNBr-cleaved (○) EL4-cell cytoplasmic extract for 1.5 h at 37 °C.

METHODS. Cells were washed four times and then used as targets for lysis by the EL4-K^b-specific CTL clones 6, 11 and 35, and the cross-species reactive K^b-specific CTL clones 52 and M37. Cytoplasmic extract from EL4 cells was prepared from 10^9 cells. Cell pellets were frozen and thawed three times, then resuspended in 20 ml PBS. Nuclei were pelleted by centrifugation at 3,500*g* for 15 min at 4 °C, and the supernatant collected and centrifuged at 20,000*g* from 30 min at 4 °C. Supernatant from the second centrifugation was lyophylized then either cleaved with 0.5*g* CNBr in 70% formic acid as previously described[27], or left untreated. Extracts were resuspended in water to ~3.0 mg ml^{-1} of protein, filtered and stored in 1 ml aliquots at −70 °C. On the day of assay, aliquots were thawed and diluted to ~750 μg ml^{-1} of protein in PBS.

of Jurkat-K^b cells to the CNBr-cleaved extract can non-specifically enhance the adhesion of Jurkat-K^b cells to CTL effectors. To test this possibility, a CNBr-cleaved extract of the human cell line JY was prepared. This extract did not sensitize Jurkat-K^b cells for lysis by EL4-K^b-specific clone 35 (Fig. 2*a*). Furthermore, we expected that if the adhesion properties of the target were altered, then there might be some increase in the lytic activity of the cross-species reactive clone M37, which lyses Jurkat-K^b cells poorly in comparison to clone 52. The activity of this potentially low-avidity clone, however, was not enhanced by sensitization of Jurkat-K^b cells. (Fig. 1, panels *d* and *e*). In addition, a K^b-restricted CTL clone that was specific for ovalbumin did not show enhanced lysis of Jurkat-K^b cells that were sensitized with CNBr-cleaved EL4-cell extract, either in the presence or absence of ovalbumin peptide (data not shown).

To determine whether the sensitizing activity of the CNBr-cleaved EL4-cell extract was due to a polypeptide, the preparation was exposed to pronase and then tested for its capacity to sensitize Jurkat-K^b target cells (Fig. 2*b*). The sensitizing activity was destroyed under these conditions, indicating its protein origin.

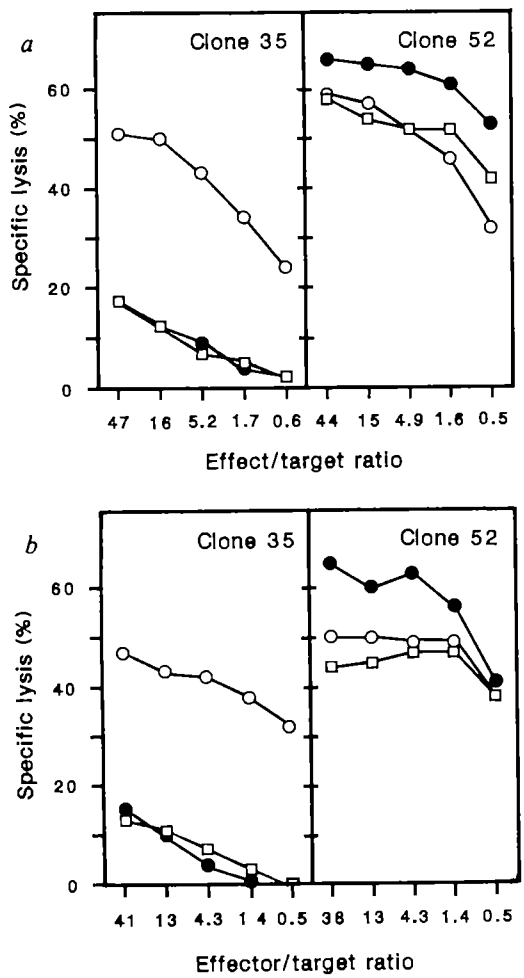

FIG. 2 *a*, Specificity of EL4-K^b-specific CTL clone 35 for EL4-derived extract. Jurkat-K^b-target cells (10^6) were exposed to ^{51}Cr for 1.5 h at 37 °C with medium alone (●), 150 μg (200 μl) CNBr-cleaved extract of EL4 cells (○), or 95 μg (200 μl) CNBr-cleaved extract of the human cell line JY (□), prepared as described in Fig. 1. Target cells were washed four times then examined for lysis by the EL4-K^b-specific CTL clone 35 or the cross-reactive K^b-specific CTL clone 52 *b*, Pronase destroys Jurkat-K^b sensitizing activity of the CNBr-cleaved EL4-cell extract Jurkat-K^b-cells were exposed to ^{51}Cr for 1.5 h at 37 °C with medium alone (●), CNBr-cleaved EL4 extract (○) or extract treated with pronase (□), and examined for lysis by the EL4-K^b-specific CTL clone 35, or by the cross-species reactive clone 52 Jurkat-K^b-sensitization was as described in Fig. 1 Pronase digestion was performed by treating 225 μg (200 μl) CNBr-cleaved EL4-cell extract with pronase (1 U) immobilized on agarose (Sigma) for 3 h at 37 °C Pronase was removed by centrifugation for 5 min at 400*g*

To establish the size of the antigenic peptide(s) present in the CNBr-cleaved EL4-cell extract, the preparation was subjected to gel-filtration chromatography on Sephadex-G25. For all three EL4-K^b-specific CTL clones, Jurkat-K^b-sensitizing activity was identified in the included volume, migrating between markers of relative molecular mass (M_r) 1,300 and 1,700 (Fig. 3). Activity profiles for each clone indicated that all three clones recognize a 10–15-amino-acid peptide.

These results indicate that EL4-K^b-specific CTL clones recognize a peptide of 10–15 amino acids present in murine but not human cytoplasm. Further specificity analysis showed that not all murine cells were lysed by these clones (Table 1). Unlike control clones such as clone 52, which recognized K^b expressed by all of the targets that we tested, EL4-K^b-specific CTL clones lysed only a fraction (20–30%) of murine lipopolysaccharide (LPS) blasts and thioglycollate-elicited peritoneal exudate cells, and failed to lyse concanavalin A (con A) blasts. Most K^b-expressing cell lines were recognized by these clones, including EL4, R8, MC57 and SV40-transformed cell lines, although little reactivity was detected against the LB27.4 cell line. This indicated that expression of the peptide(s) recognized by these EL4-K^b-specific clones may be cell-type specific or tissue-specific. On the basis of these data, we could not attribute expression to a readily identifiable cell type; for example, T lymphoma cells (EL4), but not concanavalin-A-induced T-cell blasts, were susceptible to lysis by these CTL clones. Future experiments will attempt to determine whether this represents qualitative or quantitative differences between these cells. Cell-type specificity has been observed for both class I (ref. 14) and class II (refs 15 and 16)-specific alloreactive T cells. In view of the variability of lysis among murine cells the inability of these CTL clones to recognize Jurkat-K^b cells could be potentially attributable to cell-type specificity, rather than to species specificity.

The studies described here show that the ligand of alloreactive T cells can consist of a complex of peptide and allogeneic MHC molecule, analogous to the complex of peptide and syngeneic MHC molecule recognized by antigen-specific CTLs. Whether this is the general rule is yet to be determined. The experimental system that we have described is limited to identification of only

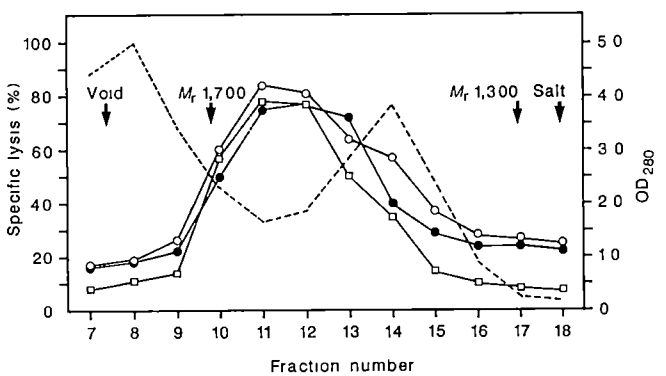

FIG 3 Sephadex-G25 elution profile of the Jurkat-K^b-cell-sensitizing activity present in CNBr-cleaved EL4-cell extract Jurkat-K^b cells were sensitized with CNBr-cleaved EL4 extract fractionated on a Sephadex-G25 column, then examined for recognition by EL4-K^b-specific CTL clones 6 (●), 11 (○) and 35 (□) CNBr-cleaved EL4-cell extract (1.8 mg in 0.6 ml) was loaded onto a 300×16 mm column of Sephadex-G25 Fractions (3 ml) were collected, lyophilized, and resuspended in 300 μl Hank's balanced salt solution Each fraction (100 μl) was used to sensitize 10^6 Jurkat-K^b cells as described in Fig. 1. Arrows indicate the position of peak fractions containing blue dextran (void), a 15-residue peptide (M_r 1,700), a 10-residue peptide (M_r 1,300), and the salt peak, determined in separate experiments Broken line indicates the optical density at 280 nm

those peptides that differ in sequence between human and murine cells or that are cell-type specific in their expression. The use of cell lines that are phylogenetically more distant for transfection with K^b may provide a larger range of antigenic differences. Finally, the approach outlined here provides a strategy that may prove useful for defining the antigenic basis for other types of CTL responses, such as those to minor histocampatibility antigens, xenoantigens and tumour-associated antigens. □

A macrophage Fcγ receptor and the mast cell receptor for IgE share an identical subunit

Chisei Ra, Marie-Hélène E. Jouvin, Ulrich Blank & Jean-Pierre Kinet*

Arthritis and Rheumatism Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, Maryland 20892, USA

Fc receptors for immunoglobulins are found on many immune cells and trigger essential functions of the immune defence system. With the exception of the high-affinity receptor for immunoglobulin E (FcεRI), these receptors were thought to consist of single polypeptides. FcεRI is a tetrameric complex of one α-subunit, one β-subunit and two γ-subunits. Here we report the cloning of a polypeptide identical to the γ-chains of FcεRI, from mouse macrophages that do not express this receptor. Biosynthetic labelling and gene transfer together show that these γ-chains associate with one of the macrophage receptors (FcγRIIa). The human homologue, FcγRIII (CD16), from natural killer cells is also expected to associate with γ-chains. It is possible that these γ-chains and the homologous ζ-chains of the T-cell antigen receptor belong to a new family of related proteins which share a common role in the signal transducing pathway.

Because Fc receptors are structurally and functionally related, the differences in their structural complexity are surprising:

$FcγRIIb_2$*	1,700±150 (n=4)	12 5±10 5 (n=7)	ND
$FcγRIIb_2+γ$*	1,177±342 (n=4)	17.5±11 5 (n=7)	ND
γ*	1±2 (n=3)	0 (n=8)	0 2±0 3 (n=3)
FcγRIIa+ζ	ND	0 (n=1)	ND
FcγRIIa+β+ζ	ND	0 (n=1)	ND

Values are means±standard deviation. The number of experiments is indicated in brackets Binding experiments. Specific binding of ^{125}I-labelled antibody 2 4G2 per 10^6 cells in each assay is given. Experiments of rosetting The number of cells forming rosettes is expressed as the per cent of the total number of cells in the assay When transfected cells were preincubated with antibody 2.4G2, the rosetting was completely inhibited (not shown). Fluorescence-activated cell sorting (FACS) experiments· The results are expressed as the per cent of specifically stained cells after subtraction of fluorescence measured when staining with non-biotinylated 2 4G2 In one of each experiment indicated by an asterisk, the relative amounts of specific transcripts for FcγRIIa and $FcγRIIb_2$ were tested in these transfectants by northern blotting and found to be equivalent A comparable amount of γ-chain transcription was also found in γ-containing transfectants. When it was possible to compare them, the results from the rosetting assay were consistent with those obtained from the FACS analysis This confirmed our previous assessment of the two assays[8]. ND, Not determined

METHODS Overlapping and similar DNA clones for γ-chains in macrophages were isolated using a rat mast cell probe for γ[3] to screen two different mouse libraries· a normal macrophage λgt11 library from Clontech (California) and a λZAP library prepared from J774 mRNA as before[8] The methods used to screen the libraries and to purify, subclone and sequence the positive clones have been described[3]. The following cDNA fragments were subcloned separately into the *Sma*I site of the SV40 promoter-driven expression vector pSVL (Pharmacia): the 834 bp *Alw*NI–*Pfl*MI fragment of FcγRIIa, the 940 bp *Bgl*I fragment of $FcγRIIb_2$, the 910 bp full-length cDNA of FcεRI β and the 389 bp *Nhe*I fragment of γ-chains from macrophage. The origin of the cDNAs for FcγRIIa, $FcγRIIb_2$ and FcεRI β has been given in Table 1 Complementary DNA for ζ-chain of the T cell antigen receptor was a gift from R Klausner. COS-7 cells were transfected with 75–100 μg DNA per 10^7 cells by electroporation at 380 V and 25 μF After 48 h the transfected cells were tested for surface expression of Fcγ receptors In binding experiments, cells were preincubated either with buffer or with a 20-fold excess of unlabelled 2 4G2 antibody for 45 min at room temperature and then incubated with a saturating amount of ^{125}I-labelled 2 4G2 antibody for 2 h at room temperature After centrifugation through oil, cell-bound radioactivity was assessed as described[14] For the IgG-rosetting assay, transfected cells were first incubated in the presence of buffer or with an excess of 2 4G2 antibody as specific inhibitor, and then with trinitrophenyl-derivatized red blood cells which had been preincubated with a saturating amount of rabbit anti-dinitrophenyl IgG (PharMingen, California). The rosetting assay was similarly performed on J774 cells as a positive control (not shown). For FACS analysis, cells were incubated either with uncoupled 2.4G2 antibody or with biotinylated 2.4G2 for 30 min on ice, then extensively washed and incubated with avidin–phycoerythrin for 30 min on ice, then again washed extensively. FACS analysis has been described[8] Northern blots were prepared as described in the legend to Table 1, except that the same probe (corresponding to identical sequences between these receptors) was used to test for FcγRIIa and $FγRIIb_2$

FcεRI has four subunits ($\alpha\beta\gamma_2$) and seven transmembrane domains, and the related Fcγ receptors have only one subunit and one transmembrane domain[1]. This striking difference and the availability of DNA probes for β (ref. 2) and γ (ref. 3) led us to investigate whether subunits like β and γ could be associated with Fc receptors other than FcεRI. Because FcεRI is found exclusively on mast cells and basophils, we looked for messenger RNAs related to β and γ in cell lines that do not express this receptor. Table 1 shows that northern blotting detects γ-mRNA but not β-mRNA in 13 out of 18 cell lines. Furthermore, we detected systematic coexpression of transcripts for FcγRIIa (ref. 4) and the γ-subunit. Notably, the immunoglobulin-binding chain of FcγRIIa shares the most homology with the α-subunit from FcεRI (refs. 5–7). In particular, both proteins share eight consecutive amino acids, including an aspartic residue, in their respective transmembrane domains.

To assess the possible structural differences between the γ-chains from mast cells and their homologues in macrophages, two mouse libraries were prepared, one from normal macrophages and another from the cell line J774. Positive clones were isolated using a rat complementary DNA probe to γ; six of these were characterized and were found to correspond in sequence to γ-cDNA clones isolated from the mast cell line PT18 (ref. 8). Therefore, at least the mRNAs for γ-chains in mouse mast cells and macrophages are identical. This supports our finding that γ-chains are encoded by a single gene[23].

We next investigated whether γ was associated with FcγRII. Using conditions that are known to maintain the non-covalent association of $\alpha\beta\gamma_2$ in FcεRI (ref. 9), biosynthetically labelled J774 cells were reacted with monoclonal antibodies 2.4G2 (specific for FcγRII) and the immune complexes were affinity-purified by a double immunospecific protocol. The immunoprecipitated eluate was then analysed by gel electrophoresis and autoradiography. Figure 1 shows that FcγRII (relative molecular mass, 50,000) co-purifies with a peptide of lower molecular weight (M_r 20,000, or 20K) when the complexes are analysed under non-reducing conditions. When analysed quantitatively, all the counts associated with the 20K component (698 ^{35}S c.p.m.) in non-reducing conditions are recovered in the 10K component (623 ^{35}S c.p.m.) observed under reducing conditions (see legend to Fig. 2). These are the precise characteristics described for the γ-subunit of FcεRI (ref. 10). Because the monoclonal antibody we have used here does not distinguish between FcγRIIa and FcγRIIb$_2$ (ref. 4), both of which are present in J774 cells (ref. 4, and Table 1), it is not possible to assess from these experiments whether the γ-chains are associated with FcγRIIa, with FcγRIIb$_2$, or with both and so we cannot determine its stoichiometry.

Co-transfection of associated subunits has been shown to be a critical factor for efficient surface expression of various portions of multisubunit receptors such as the asialoglycoprotein receptor[11], the T-cell receptor[12], the CD3 complex[13] and FcεRI (refs. 3, 14). For this reason, we compared the efficiency of surface expression of the respective receptors in COS-7 cells transfected with FcγRIIa or FcγRIIb$_2$. We confirmed an earlier report[15] that expression of FcγRIIb$_2$ is much more efficient than expression of FcγRIIa (Table 2). When cells were transfected simultaneously with DNAs encoding γ-subunit and FcγRIIb$_2$, the efficiency of expression of this receptor was not increased. By contrast, co-transfection with the genes for γ and FcγRIIa dramatically increased the efficiency of surface expression of this receptor. Interestingly, the number of rosetting cells expressing FcγRIIb$_2$ or FcγRIIa + γ is comparable. The total number of receptors is higher in cells expressing FcγRIIb$_2$ than in those expressing FcγRIIa + γ, however, although transcription for each receptor was found equivalent (data not shown). This may

The cell lines (numbers 1, 3–6, 15 and 18) were obtained from American Type Culture Collection and their RNA extracted as before[5] The PT18 cell line (2) and the T lymphoma NTD (14) have been described[22] and the other cell lines (7–13, 16, 17) were originally obtained from the Hazelton Laboratory (Rockville, Maryland) and their RNA supplied by K. Huppi. Northern blots and hybridization were as before[5] and used the following cDNA probes the 632 base-pair (bp) *Hin*dIII fragment specific for mouse FcεRIα, the full-length 910 bp fragment of mouse FcεRIβ, the 418 bp *Hin*cII fragment specific for FcεRIγ, the 191 bp *Bam*HI fragment specific for mouse FcγRIIa (ref 4), and the 187 bp *Bam*HI fragment specific for mouse FcγRIIb (ref 4) The sequences of FcεRI α and γ probes described here were chosen so as to avoid any overlap with sequences of homologous portions of FcγRIIa and of T-cell receptor ζ-chains respectively. Cell lines (numbers 1–6, 14, 15 and 18) were also tested in non-stringent conditions (not shown) with the rat cDNA probes for α, β and γ of FcεRI (refs 2, 3 and 5) In these conditions, the results were similar to those described in the Table The original cDNA clones of FcγRII a and b$_2$ were a gift from J. Ravetch Here we use Latin rather than Greek letters to define the different forms of FcγRII to avoid confusion with the subunits associated with FcεRI and FcγRII, for which we use Greek letters. The DNA sequences of the three subunits of mouse FcεRI are reported elsewhere[8] and the cDNAs are available on request. ND, not determined

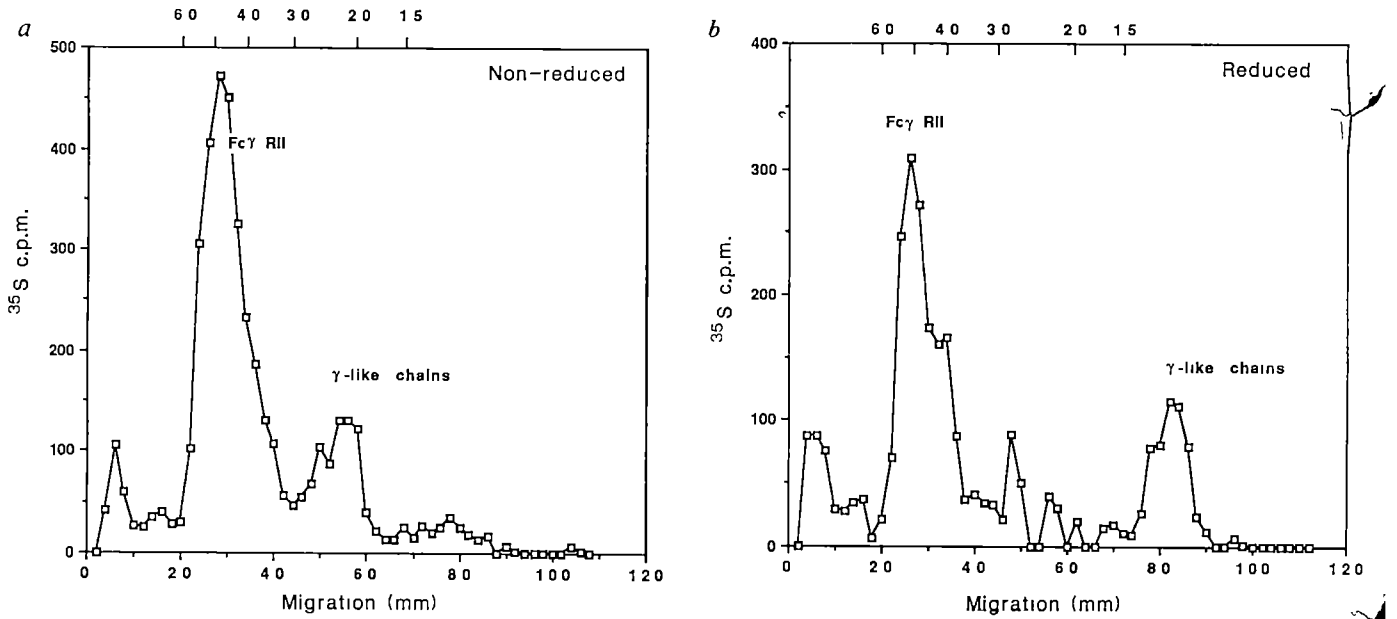

FIG. 1 Association of FcγRII with γ-chains FcγRII receptors were purified from J774 cells labelled with ^{35}S-cysteine in 'non-dissociating' conditions and analysed by gel electrophoresis in *a*, the absence and *b*, the presence of reducing agent. M_r calibration (in thousands) is shown along the top in *a* and *b*

METHODS J774 cells were biosynthetically labelled with ^{35}S-cysteine by methods already described for rat basophilic leukaemia cells[10]. The cells were bound to monoclonal antibody 2 4G2 (ref. 4), which has been derivatized with trinitrophenyl and iodinated with ^{125}iodine[22]. Cells were then washed extensively to prevent low-affinity binding of monoclonal antibodies and solubilized at 5×10^7 cells per ml in borate-buffered saline containing 10 mM CHAPS (3-[(3-cholamidopropyl)dimethyl ammonio]-1-propane-sulphonate) and the same concentration of enzymatic inhibitors as before[9]. The trinitrophenyl–antibody–receptor complexes were reacted with control beads or with Protein A-Sepharose beads that had been coupled with rabbit IgG antidinitrophenyl antibodies[22] and the beads were washed extensively with borate-buffered saline containing 10 mM CHAPS and 2 mM phospholipids extracted from a tumour of rat basophilic leukaemia cells[9]. The trinitrophenyl–antibody–receptor complexes were eluted in the same buffer but containing 5 mM dinitrophenyl-ε-amino caproate and immunoprecipitated with goat anti-rat IgG (Jakson Immuno, Pennsylvania) and protein G beads (Pharmacia). After washing in 2 mM CHAPS, the precipitated material was counted for ^{125}I. The overall yield of antibody-bound receptors at this stage was estimated to be ~10%. For example, in one of four experiments, 12×10^{12} receptor molecules were recovered from 7.5×10^7 cells, assuming divalent binding of 2 4G2 to the receptor. The pellet was then extracted in 1.25% SDS in gel sample buffer (containing 10% β-mercaptoethanol for reducing conditions) and applied to a 12.5% SDS-polyacrylamide gel. After electrophoresis, the gel was dried and autoradiographed. Each lane was cut into 2 mm slices for counting for ^{125}I and ^{35}S. The ^{35}S profiles shown here have been corrected for the overlapping ^{125}I counts arising from labelled antibodies. The eluate from the non-specific affinity column and the control immunoprecipitates were analysed and gave only a few counts at the top of the running gel. In non-reducing conditions, the ^{35}S associated with the γ-like peak gave 698 c.p.m. and the ^{125}I associated with the IgG peak gave 2,472 c.p.m. Under reducing conditions, there were 580 ^{35}S c.p.m. associated with the γ-like peak and 2,300 total ^{125}I counts associated with the heavy and light chains. The c.p.m. in the reduced γ-like peak (580 c.p.m.) can be corrected for the amount of ^{125}I loaded in the non-reduced lane for purposes of comparison (623 c.p.m.)

reflect the requirement imposed on FcγRIIa to assemble with γ-chains.

Taken together, these data demonstrate that FcγRIIa from macrophages share identical γ-chains with the mast cell receptor FcεRI. The γ-chains associated with FcγRIIa have probably not been detected before because of their easy dissociability, noted previously for FcεRI (refs 9, 16 and 17).

It is now established that human FcγRIII in natural killer cells[18,19] is the human homologue of mouse FcγRIIa (ref. 20). With the α-chain of FcεRI, they each share the same eight consecutive residues in the transmembrane domain. Human FcγRIII from natural killer cells will probably also be found to associate with γ-chains. Indeed, preliminary experiments using the polymerase chain reaction indicate that γ-chains are also present in human natural killer cells (M-H.E.J. and J-P.K., unpublished results).

Because γ-chains of Fc receptors and ζ-chains of T-cell receptors[21] not only share homologous segments[14], but are also located on the same mouse chromosome 1 (ref. 23), it is possible that they originate from a common ancestor. If so, their possible functional relationship may help to solve the most interesting question: how do all these receptors work? □

A cytosolic binding protein for the immunosuppressant FK506 has peptidyl-prolyl isomerase activity but is distinct from cyclophilin

John J. Siekierka, Shirley H. Y. Hung, Martin Poe, C. Shirley Lin & Nolan H. Sigal

Departments of Immunology Research and Enzymology, Merck, Sharp and Dohme Research Laboratories, PO Box 2000 Rahway, New Jersey 07065, USA

CYCLOSPORIN A and the newly discovered immunosuppressant, FK-506, are potent inhibitors of T cell activation[1]. In addition to their clinical importance in the prevention of allograft rejection, cyclosporin A and FK-506 represent important reagents for the study of the molecular mechanisms of lymphocyte activation. Cyclosporin A, a cyclic undecapeptide and FK-506, a macrolide, although chemically distinct, inhibit similar lymphocyte activation responses[1,2]. The earliest responses inhibited in the T cell seem to be the expression of early phase T cell-activation genes for interleukins 2, 3 and 4, granulocyte-macrophage colony stimulating factor and gamma interferon[2–4]. Although FK-506 and cyclosporin A seem to inhibit similar signal transduction processes, they do so by interacting with distinct cytosolic proteins[5,6]. We report here the purification to homogeneity of a specific FK-506 binding protein that is distinct from the cyclosporin A-binding protein, cyclophilin[7,8]. In addition, we show that this FK-506 binding protein, like cyclophilin, has peptidyl-prolyl isomerase activity[9,10].

In a preliminary study[6], we found that the potent immunosuppressive agent, FK-506, was rapidly taken up by T cells and was largely associated with a low molecular weight cytoplasmic component. Using cytosol prepared from the JURKAT T-cell line, we purified to apparent homogeneity a specific FK-506 binding protein (FKBP). This binding protein represents ~0.4% of the total cytoplasmic protein in JURKAT cells (Table 1), a value similar to that reported for cyclophilin (0.1–0.4%; ref. 11). A summary of the purification procedure is given in Table 1. Electrophoresis (Fig. 1, lane 2) of the purified FKBP reveals a single homogeneous band with a relative molecular mass of 10,000–11,000 (10–11K), in agreement with the value previously obtained by HPLC gel filtration[6] and lower than the molecular mass of cyclophilin (Fig. 1, lane 3 and ref. 11). Purified FKBP had a specific activity of 26 μg of FK-506 bound per mg of protein, with protein determined by the Bradford assay[12]. The theoretical value expected for a 1:1 molar complex of FK-506 to FKBP is 73–80 μg mg^{-1}; the Bradford protein assay, however, seems to overestimate the actual quantity of FKBP protein by approximately threefold when compared with other methods

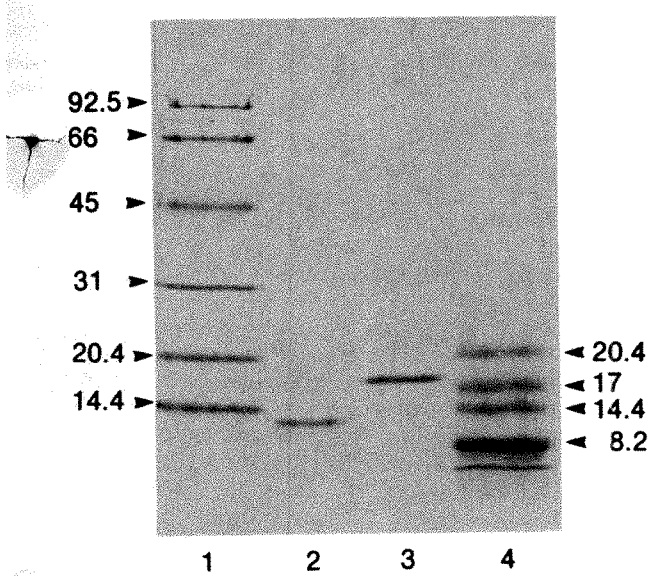

FIG. 1 SDS-PAGE of purified FK-506 binding protein and calf thymus cyclophilin. Lane 1, protein standard; lane 2, FK-506 binding protein; lane 3, calf thymus cyclophilin; lane 4, low molecular weight standards (Enprotech). Molecular weights are shown in thousands.
METHODS. HPLC CM 300-purified FKBP (3 μg) and calf thymus cyclophilin (3 μg)[11] were electrophoresed on a 12% polyacrylamide gel using a Mini-Protean II slab gel apparatus (Bio-Rad). Gels were stained with Coomassie blue.

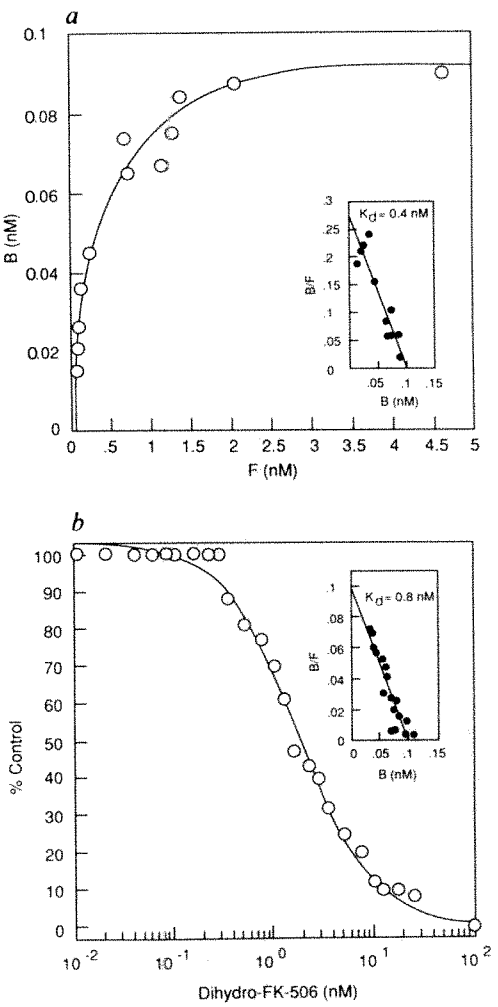

FIG. 2 Binding of [^{3}H]dihydroFK-506 to the cytosolic binding protein. *a*, Direct binding of [^{3}H]dihydroFK-506 to FKBP. *b*, Competitive binding of [^{3}H]dihydroFK-506 with unlabelled dihydroFK-506. Insets illustrate the data plotted in the Scatchard format. *B*, Concentration of [^{3}H]dihydroFK-506 specifically bound; *F*, that which is free.
METHODS. Assays were conducted in 96-well microtitre plates previously treated with the siliconizing agent Sigmacote (Sigma). The assays contained 20 mM sodium phosphate (pH 7.2), 0.5% BSA, 1.25 ng ml^{-1} purified FK-506 binding protein (step V) and the amounts of [^{3}H]dihydroFK-506 indicated. The mixtures were incubated for 20 min at 25 °C and assayed by the LH-20 assay as described (Table 1). Competitive binding assays were the same as direct binding, except that assays contained 1.8 nM [^{3}H]dihydroFK-506 and the indicated amounts of unlabelled competitor. The binding data were analysed using the LIGAND program[13] and the data plotted in the Scatchard format.

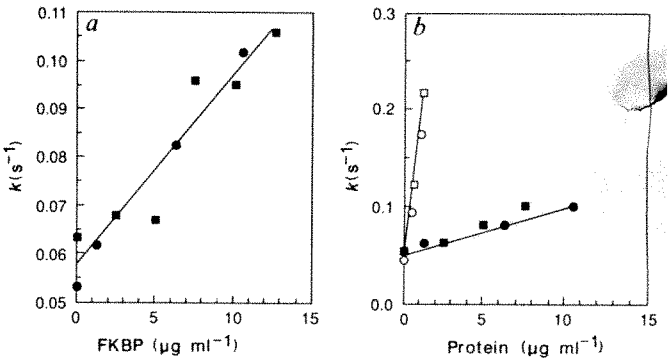

FIG. 3 FKBP peptidyl-prolyl *cis-trans* isomerase activity (PPIase). *a*, PPIase activity as a function of FKBP concentration. Different symbols represent the results of experiments with two different preparations of FKBP (step V). *b*, Comparison of PPIase activity associated with cyclophilin (open symbols) and FKBP (Step V) (closed symbols). Symbols as above.
METHODS. PPIase activity was assayed essentially as described[10]. The assay measures the '*cis*' to '*trans*' isomerization of the proline–alanine peptide bond in the peptide, *N*-succinyl-Ala-Ala-Pro-Phe-*p*-nitroanilide. The '*trans*' form of the peptide is readily cleaved by chymotrypsin with the release of *p*-nitroanilide which is quantitated spectrophotometrically at 405 nm. At equilibrium, 88% of the peptide is present as the '*trans*' form. The remaining 12% of the peptide present in the '*cis*' form is cleaved on enzymatic conversion to the '*trans*' form. Reactions (1.0 ml) were at 25 °C and contained 0.1 mM substrate (Sigma) added as a 30 μl aliquot of a 2.1 mM stock in dimethyl sulphoxide, 100 mM Tris-HCl (pH 7.8), cyclophilin or FKBP (step V, Table 1) and, where indicated, either CsA or FK-506. After 1 min, 30 μl of 2 mg ml^{-1} chymotrypsin (Sigma) in 100 mM Tris-HCl (pH 7.8) was added. After mixing, the increase in absorbance at 405 nm was measured in a Beckman DU68 spectrophotometer at 3 s intervals. The log of the difference between absorbance at steady state and absorbance at time *t* was plotted against time. The first order rate constant, *k* (s^{-1}), is calculated from the slope of the resulting straight line.

such as ultraviolet absorbance and amino-acid analysis (D. Boulton *et al.*, manuscript in preparation). A similar observation has been reported for cyclophilin[11]. Correcting the binding data for this discrepancy would yield a specific activity of 78 μg mg^{-1}, indicating the formation of a 1 : 1 complex of FK-506 and FKBP. Preliminary sequence analysis revealed a single N-terminus, indicating that the protein represents a single homogeneous species. In addition, no homology between this sequence and that of cyclophilin was observed; FKBP does not, therefore, seem to be a processed form of cyclophilin (D. Boulton *et al.*, manuscript in preparation).

Binding of [^{3}H]dihydroFK-506 to FKBP is saturable and of high affinity (Fig. 2*a*). Cyclosporin A (CsA) at concentrations ≤1 μM, failed to compete with FK-506 for binding (data not shown). Scatchard analysis of the direct binding data yields a dissociation constant (K_d) of 0.4 nM for the interaction (Fig. 2*a*, inset). In addition, competition binding data were analysed using the LIGAND computer program[13]. The data best fits a single-site model with a K_d of 0.8 nM (Fig. 2*b*, inset), consistent with the direct binding approach. The K_d values obtained by these two approaches are similar to the concentration of dihydroFK-506 that caused 50% inhibition of interleukin-2 (IL-2) secretion in JURKAT cells stimulated with phorbol myristate acetate /ionomycin (1.1 nM; ref. 6). These results are consistent with the notion that the immunosuppressive activity of FK-506 is mediated by its interaction with this binding protein.

It has recently been demonstrated[9,10] that cyclophilin is identical to peptidyl-prolyl isomerase (PPIase), an enzyme that catalyses the *cis–trans* isomerization of proline residues in proteins and peptides. In addition, CsA was found to inhibit cyclophilin PPIase activity at concentrations similar to those that inhibit T cell activation. The catalysis of proline *cis–trans* isomerization is believed to be important in folding of proteins into their native conformations. It has also been proposed that

TABLE 1 Purification of FKBP from JURKAT Cells

	Purification step	Volume (ml)	Protein (mg ml^{-1})	Specific activity (μg FK-506 bound per mg protein)	Total binding capacity (μg FK-506)	Recovery (%)
I	S-100	127	8.06	0.076	77.8	100
II	56 °C, 20 min	114	2.59	0.17	50.2	65
III	Affigel Blue	2.2	4.59	3.63	39.5	51
IV	TSK-125 HPLC	2.2	0.64	12.90	18.2	23
V	CM 300 HPLC	0.77	0.17	25.66	3.4	4.3

FK-506 and [^{3}H]dihydroFK-506 (specific activity, 49 mCi mg^{-1}) were prepared as previously described[2,6]. Binding of [^{3}H]dihydroFK-506 to JURKAT protein fractions was assayed by the LH-20 assay[7] with 30 nM [^{3}H]dihydroFK-506 and 0.1–10 μg protein. Bound [^{3}H]dihydroFK-506 was separated from free [^{3}H]dihydroFK-506 by chromatography on individual 2 ml Sephadex LH-20 columns (Pharmacia) (ref. 7). Samples (500 μl) were mixed with 3.0 ml Aquasol-2 (New England Nuclear, Boston) and counted in a LS-9000 scintillation counter (Beckman Instruments) at 50% efficiency. JURKAT cells (clone 77. 6.8, a gift from Dr Kendall Smith) were cultured in RPMI 1640 media (Cellgro) containing 1% penicillin/streptomycin, 1 mM glutamine (both from Gibco Laboratories) and 10% heat-inactivated fetal calf serum (Hazleton Biologics). Approximately 70 × 10^9 cells were washed twice with 150 ml PBS and pelleted by low-speed centrifugation. The cells were disrupted by Dounce homogenization in 4 volumes of buffer containing 10 mM Tris-HCl (pH 7.5), 100 mM KCl, 5 mM 2-mercaptoethanol, 0.5 mM PMSF and 1 mM EDTA, and centrifuged at 500*g* for 20 min. After centrifugation for 1 h at 100,000*g*, the supernatant was heated for 20 min at 56 °C, precipitated protein removed by centrifugation and the resulting supernatant concentrated in an Amicon ultrafiltration cell with a YM5 membrane (Amicon). The same procedure was used to concentrate protein in subsequent steps. The concentrated protein was dialysed against buffer containing 5 mM 2-mercaptoethanol, 0.5 mM PMSF, 1 mM EDTA and 10 mM KH_2PO_4 (pH 7.2) and applied to a 1.5 × 40 cm Affigel Blue column (Bio-Rad) equilibrated with the same buffer. Protein was eluted with a linear gradient (180 ml total) of 10–200 mM KH_2PO_4 containing 5 mM 2-mercaptoethanol, 0.5 mM PMSF and 1 mM EDTA. Fractions (2.5 ml) were collected and assayed for FK-506 binding. The peak of activity (at ~50 mM KH_2PO_4) was dialysed against buffer containing 20 mM NaH_2PO_4, 50 mM Na_2SO_4 (pH 6.8), 5 mM 2-mercaptoethanol, 0.5 mM PMSF and 1 mM EDTA, and concentrated and fractionated by HPLC on a TSK-125 gel filtration column (21 × 600 mm, Bio-Rad). Fractions (4 ml) were assayed and the peak of activity pooled and dialysed against buffer containing 5 mM KH_2PO_4 (pH 6.8), 5 mM 2-mercaptoethanol, 0.5 mM PMSF and 1 mM EDTA. The protein was concentrated and fractionated by weak ion exchange on a SynChropak CM 300 column (4.6 × 250 mm, Rainin Instruments). Protein was eluted isocratically at a flow rate of 0.3 ml min^{-1} with buffer of the same composition as the dialysis buffer. Fractions (0.3 ml) were assayed and the peak of activity pooled and concentrated. The purified protein was stored at 0 °C for short periods and −80 °C for extended periods. Protein was determined by the Bradford assay (Bio-Rad) with IgG as the standard.

proline *cis–trans* isomerization may be involved in regulating signal transduction by membrane receptors and membrane transport proteins[14]. It is interesting, therefore that the *ninaA* gene product, which is required for visual transduction in *Drosophila*, has extensive sequence homology to cyclophilin[15]. These observations indicate that cyclophilin may have a regulatory role in T cell signal transduction through its PPIase activity. We have found that FKBP, like cyclophilin, catalyses the *cis–trans* isomerization of the Ala-Pro bond in the peptide, *N*-succinyl-Ala-Ala-Pro-Phe-*p*-nitroanilide (Fig. 3*a*). Cyclophilin, under similar conditions, exhibits a 25-fold greater activity per mg of protein than FKBP (Fig. 3*b*). The lower PPIase activity associated with FKBP is not due to heat inactivation of the catalytic site during purification because FKBP prepared without the heat treatment step had essentially the same activity before and after heat treatment (data not shown); it may, therefore, reflect a more stringent substrate requirement. The physiologically relevant substrates for both cyclophilin and FKBP have not yet been identified. FKBP PPIase activity is specifically inhibited by FK-506 (Fig. 4*a*), whereas CsA at a concentration of 1 μM had no effect. These data rule out the possibility that the FKBP activity is due to contamination by cyclophilin. The large amount of FKBP used in these assays (>7 μg ml^{-1}; 0.7 μM) precludes a valid comparison of the concentration of FK-506 needed for half-maximal PPIase inhibition (IC_{50}) with the IC_{50} for FK-506 in the JURKAT IL-2 assay. Cyclosporin A is a potent inhibitor of cyclophilin PPIase activity (Fig. 4*b*), whereas FK-506 at a concentration of 1 μM gave no inhibition. These data further support our contention that FKBP and cyclophilin are distinct proteins with distinct ligand specificities.

The isolation of a unique protein (FKBP) that binds the potent immunosuppressive agent, FK-506, provides further insight into the molecular basis of T cell activation and immunosuppression. Although FKBP is distinct from cyclophilin by a number of criteria, the two proteins do share several common properties. Both proteins are abundant, are found mainly in the cytoplasmic compartment of cells, have low molecular weights, bind immunosuppressive ligands and exhibit PPIase activity that is specifically inhibited by ligand binding.

Both the immunosuppressive agents FK-506 and CsA share a number of common cell-biological properties. In both T and B lymphocytes, we and others[1,16,17] have been unable to distinguish between the effects of FK-506 and CsA when the cells have been triggered with pharmacological agents or cell-surface molecules that use different intracellular activation pathways. In particular, the ability of either FK-506 or CsA to inhibit these events was found to vary in the same way, according to the mode of cellular activation. In general, only activation pathways that caused a measurable rise in intracellular Ca^{2+} were FK-506/CsA-sensitive[16,18]. For example, FK-506 and CsA inhibited activation through the CD3 pathway, but not proliferation induced through the CD28 pathway, in human lymphocytes[16]. PPIases may interact with such Ca^{2+}-dependent signal transduction pathways by influencing the conformation of protein kinases, ion channels or transcription factors in lymphocytes. The finding that FKBP, like cyclophilin, possesses PPIase activity, is evidence that the PPIase activity of both proteins plays a critical part in T cell activation. The molecular mechanism(s) that involves such an isomerase activity in lymphocyte-specific signal transduction events remains to be discovered. There is genetic evidence that cyclophilin-like molecules participate in a defined signal transduction pathway (visual transduction) and that a photoreceptor cell-specific form of this enzyme may exist[15]. We hypothesize that there are specific substrates or unique forms of the enzyme in lymphocytes which explain the selective sensitivity of this cell type to these immunosuppressive agents. The potential existence of a cyclophilin gene family[15,19,20] supports the hypothesis that cell-specific forms of cyclophilin (and perhaps FKBP) may exist. These observations lead us to suggest that FKBP and cyclophilin, through their peptidyl-prolyl isomerase activity, may be important in T cell activation. □

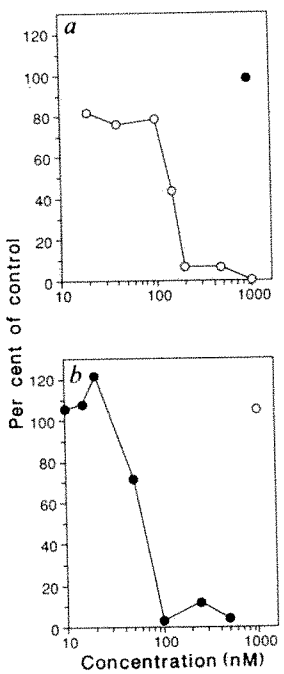

FIG. 4 Effect of FK-506 and CsA on FKBP and cyclophilin PPIase activity. *a*, Inhibition of FKBP (step IV) PPIase activity by FK-506, open circles; CsA, closed circle. *b*, Inhibition of cyclophilin PPIase activity by CsA, closed circles; FK-506, open circle.

METHODS. PPIase activity was assayed as described for Fig. 3. Stock solutions of FK-506 and CsA (1 mg ml^{-1}) were prepared in ethanol and diluted with assay buffer to the concentrations indicated. Step IV (Table I) FKBP was present at 31.4 μg ml^{-1} in *a*. Step IV FKBP was used to facilitate the quantitation of FKBP PPIase activity at lower enzyme concentrations. Cyclophilin was present at 0.44 μg m^{-1} in *b*. Addition of ethanol had no effect on the PPIase assays.

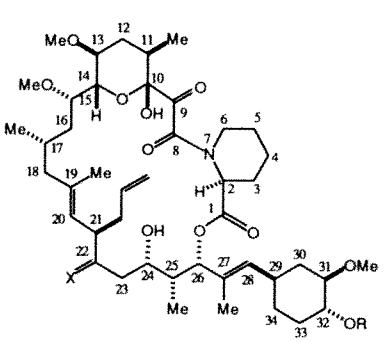
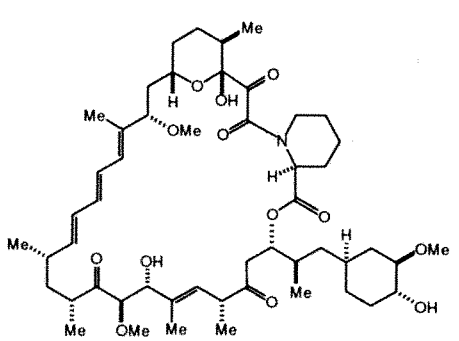
A receptor for the immunosuppressant FK506 is a *cis–trans* peptidyl-prolyl isomerase

Matthew W. Harding, Andrzej Galat,† David E. Uehling† & Stuart L. Schreiber†



Division of Organ Transplantation and Immunology, Department of Surgery, Yale University School of Medicine, 310 Cedar St, New Haven, Connecticut 06510, USA
† Department of Chemistry, Harvard University, 12 Oxford Street, Cambridge, Massachusetts 02138, USA



THE structurally novel macrolide FK506 (refs 1,2) has recently been demonstrated to have potent immunosuppressive activity[3–7] at concentrations several hundredfold lower than cyclosporin A (CsA). Cyclosporin A, a cyclic peptide, has found widespread clinical use in the prevention of graft rejection following bone marrow and organ transplantation[8]. The mechanisms of immunosuppression mediated by FK506 and CsA appear to be remarkably similar, suggesting that these unrelated structures act on a common receptor or on similar molecular targets, perhaps the CsA receptor, cyclophilin[9–11], which has recently been shown by Fischer *et al.*[12] and Takahashi *et al.*[13] to have *cis–trans* peptidyl-prolyl isomerase activity. We have prepared an FK506 affinity matrix and purified a binding protein for FK506 from bovine thymus and from human spleen. This FK506-binding protein (FKBP) has a relative molecular mass (M_r) of ~14,000(14K), a pI of 8.8–8.9, and does not cross-react with antisera against cyclophilin. The first 40 N-terminal residues of the bovine and 16 residues of the human FKBP were determined; the 16-residue fragments are identical to each other and unrelated to any known sequences. This protein catalyses the *cis–trans* isomerization of the proline amide in a tetrapeptide substrate and FK506 inhibits the action of this new isomerase. The FKBP and cyclophilin appear to be members of an emerging class of novel proteins that regulate T cell activation and other metabolic processes, perhaps by the recognition (and possibly the isomerization) of proline-containing epitopes in target proteins.

FK506 (Fig. 1; *1*) and CsA (Fig. 1; *6*) affinity matrices were prepared using an FK506 amino derivative, synthesized as described in the legend to Fig. 1, and an 8′-ornithine CsA derivative, respectively. When cytosol extracts of bovine thymus and of human spleen were adsorbed onto the FK506 matrix and the column eluted with FK506, a single protein of ~14K was obtained (Fig 2, lanes 1 and 5). FK506 also displaced a 14K protein from the FK506 matrix in experiments with cytosol extracts of bovine kidney, human and murine liver, and EL4 cells. Analogous experiments with the CsA matrix eluted with CsA produced bovine and human cyclophilins, a 14K bovine protein, and human proteins of M_rs 15K, 36K and 40K (Fig. 2, lanes 2 and 6). No proteins were retained in a control experiment with a non-derivatized matrix (Affigel-10 capped with ethanolamine). The similarity of FK506 and CsA binding proteins was analysed by immunoblotting. Affinity-purified rabbit anti-cyclophilin IgG reacted strongly with bovine and human cyclophilins and the bovine CsA displaced 14K protein (Fig. 2, lanes 4 and 8), but did not react with the bovine and human FK506-displaced 14K proteins (Fig. 2, lanes 3 and 7). These data indicate that the FKBP is antigenically unrelated to cyclophilin. The 15K, 36K and 40 K human spleen proteins were not recognized by the antiserum (Fig. 2, lane 8).

The bovine FKBP was found to have an N-terminal sequence of H_2N-Gly-Val-Gln-Val-Glu-Thr-Ile-Ser-Pro-Gly-Asp-Gly-Arg-Thr-Phe-Pro-Lys-Arg-Gly-Gln-Thr-Cys-Val-Val-His-Tyr-Thr-Gly-Met-Leu-Glu-Asp-Gly-Lys-Lys-Phe-Asp-Ser-Ser-Arg-. The first 16 residues of the human protein were determined and found to be identical to the corresponding bovine sequence. Isoelectric focusing of the bovine and human FKBPs revealed a pI of 8.8–8.9. Comparison of the N-terminal 40-amino-acid sequence (*vide supra*) with the NBRF protein sequence database (release 20.0, 3/89) and of the human and murine complementary DNA sequences corresponding to amino acids 7–29 (unpublished results of R. F. Standaert, G. L. Verdine and S.L.S.) with the GenBank (release 59.0, 3/89) and EMBL (release 18.0, 2/89) databases failed to identify any significant similarity to known sequences. These FK506-binding proteins appear to represent a previously unidentified class of conserved proteins.

In order to examine drug binding to the native protein, a chromatographic procedure (without use of the affinity reagent; see Fig. 1; *4*) was developed that gave rise to homogeneous drug-free bovine and human FKBP (Fig. 2*c*). The identity of

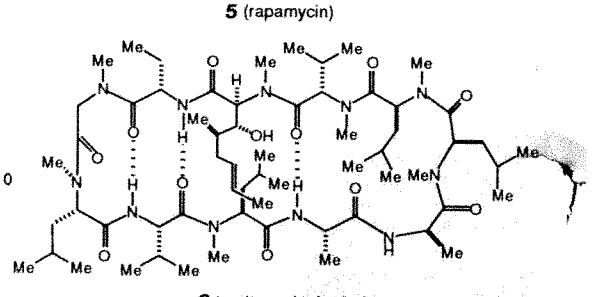


FIG. 1 Structure of FK506, *1*; rapamycin, *5*; cyclesporin A, *6*; the reaction sequence for the synthesis of FK506-affigel, *3*; and [^{14}C]benzoyl derivatives, *4*.
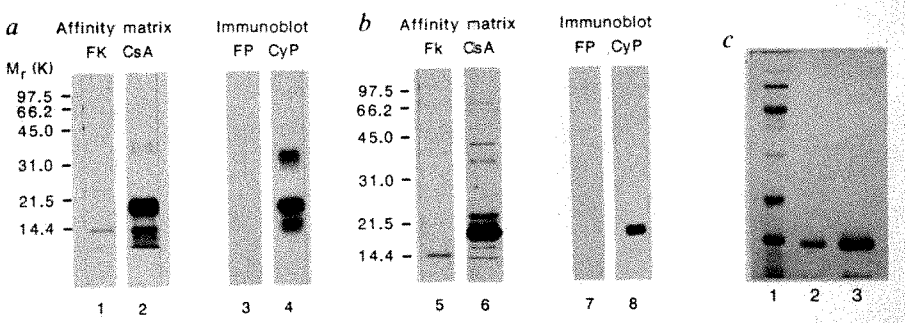
METHODS. The synthesis of the FK506-affinity reagent began with the stereoselective reduction of the C(22) ketone in *1* with L-Selectride[20] and generated the tetraol, *2*. Selective acylation of the C(32) hydroxyl with β-azidoproprionic acid was achieved by the conversion of this reagent to the corresponding acid chloride followed by a reaction with *2*. Chemoselective reduction of the azide proceeded under the conditions of Knowles[21] and generated an FK506-amino derivative (structure not shown). For preparation of the affinity matrices, the FK506-amino and 8′-ornithine CsA derivatives were diluted in ethanol to 1 mg ml^{-1} and mixed with an equal volume of Affigel 10 (BioRad) for 4 h at room temperature with 0.1 N $NaHCO_3$. Unbound drug was recovered by washing the resins with isopropanol. Unreacted groups were blocked by shaking for 4 h with 200 mM ethanolamine·HCl in 0.1 N $NaHCO_3$. TLC analysis of wash fractions indicated > 85% coupling of FK506. The efficiency of CsA coupling was not quantitated but was presumed to be similar. 32-[1-^{14}C]-labelled FK506 analogue *4* was prepared by selective benzoylation of *1*.

the proteins obtained in this manner with the material eluted from the affinity matrix was determined by N-terminal amino-acid sequencing. The binding of 32-[1-^{14}C]-benzoyl-FK506 (Fig. 1;*4*) shows a linear dependence on the FKBP concentration (Fig. 3*a*), but [^{3}H]-labelled CsA does not bind to this protein (data not shown). Titration with unlabelled FK506 (Fig. 1;*1*) displaces the radioligand from its complex in a concentration-dependent manner (Fig. 3*b*). In a competitive LH-20 binding assay[14], CsA was not displaced from cyclophilin, even by a 500-fold molar excess of FK506. Specificity of FK506 and CsA



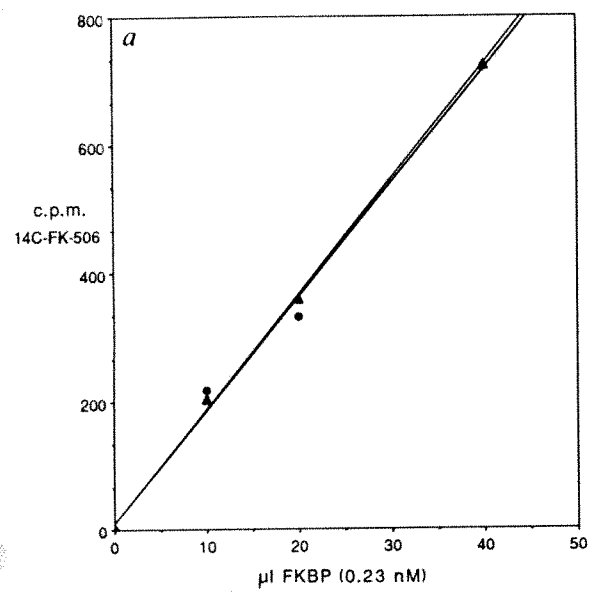


FIG. 2 Purification of FK506 and CsA-binding proteins from bovine thymus, *a*, and human spleen, *b*, tissue by affinity adsorption and ligand displacement. Bovine (lane 1) and human (lane 5) FKBP were obtained by elution with FK506. Cyclophilins and other putative CsA-binding or cyclophilin-associated proteins were purified from thymus (lane 2) and spleen (lane 6) by elution with CsA. Bovine (lane 3) and human (lane 7) FKBP do not react with affinity purified rabbit anti-cyclophilin IgG. Bovine (lane 4) and human (lane 8) cyclophilin and a 14K bovine protein react with anti-cyclophilin IgG. The 15, 36 and 40K human proteins (lanes 6 and 8) appear to be antigenically unrelated. *c*, Silver staining of homogeneous bovine FKBP purified by chromatographic methods. Samples of 1 μg (lane 2) and 2.5 μg (lane 3) were resolved by SDS-PAGE (12.5% gel).

METHODS. Calf thymus and human spleen tissue were homogenized (1:4 w/v) in 10 mM Tris-HCl (pH 7.4), 120 mM KCl, 5 mM 2-mercaptoethanol and 1 mM PMSF. Homogenates were centrifuged at 8,000*g* for 20 min, then at 21,000*g* for 45 min and supernatants were clarified by filtration through a 0.45 μm membrane. Filtrates were diluted to 2–3 mg protein ml^{-1} and 45–50 ml passed through 0.5 ml FK506 or CsA Affigel columns. After extensive washing with phosphate-buffered saline–0.05% Tween 20 (50 ml) and then 5 mM Tris-HCl (pH 7.4), 5 mM 2-mercaptoethanol (5 ml), the proteins were recovered by batch elution of the affinity resin with FK506 (500 μg ml^{-1}), rapamycin (500 μg ml^{-1}) or CsA (100 μg ml^{-1}) in a total volume of 1 ml. Approximately 15–30 μg of drug-binding proteins were recovered in each affinity matrix experiment. Elution fractions were lyophilized, and the proteins were resolved by reducing SDS-PAGE (12.5% gels) and identified by silver staining. Drug additions were made from stock solutions at 10 mg ml^{-1} in 100% ethanol. Drug concentrations for elution were chosen to equal the concentration of matrix-bound drug. At this concentration, CsA formed a microcrystalline solution which was completely effective at receptor displacement. For purification of drug-free FKBP, clarified tissue homogenates were heated at 60°C for 20 min. Supernatants harvested after centrifugation at 20,000*g* were concentrated, dialysed against 20 mM Tris-HCl (pH 7.4) and chromatographed on a DEAE Sepharose column (1.6 cm internal diameter × 40 cm) equilibrated with dialysis buffer. The void fractions were recovered, concentrated and molecular weight fractions separated on a Sephacryl S100HR column (2.5 cm internal diameter × 90 cm) equilibrated with 20 mM Tris-HCl (pH 7.4), 150 mM NaCl. The low molecular weight (10–20 K) fraction was recovered and dialysed extensively against 5 mM Tris-HCl (pH 6.9) and the resulting proteins were resolved on a Synchropak CM-300 HPLC column (4.6 mm internal diameter × 25 cm) by isocratic elution with 5 mM Tris-HCl (pH 6.9), 5 mM NaCl at 1 ml min^{-1}. The FK506 binding activity of resolved proteins was monitored by Sephadex LH-20 partition assay as described[9] and the FKBP was associated with a single peak with a retention time of 7 min. Homogeneity of human and bovine FKBP was verified by silver staining after SDS-PAGE (panel *c*), isoelectric focusing and N-terminal sequence analysis. This protocol achieved a recovery of approximately 2 μg FKBP mg^{-1} of protein in the original clarified tissue homogenates. For immunoblotting, proteins were electrotransferred[22] to nitrocellulose and blots were developed with affinity-purified rabbit anti-cyclophilin IgG (1 μg ml^{-1}) and ^{125}I-protein A (2 × 10^{5} c.p.m. ml^{-1}). For sequence analysis, proteins were electroblotted to PVDF membranes as described by Matsudaira[23] and membrane pieces were loaded into the cartridge of an Applied Biosystems Model 477A gas phase sequencer with on-line PTH amino-acid analysis. Initial couplings and repetitive yields of 207pmol/89% and 21 pmol/87% were calculated for the bovine and human sequences, respectively.

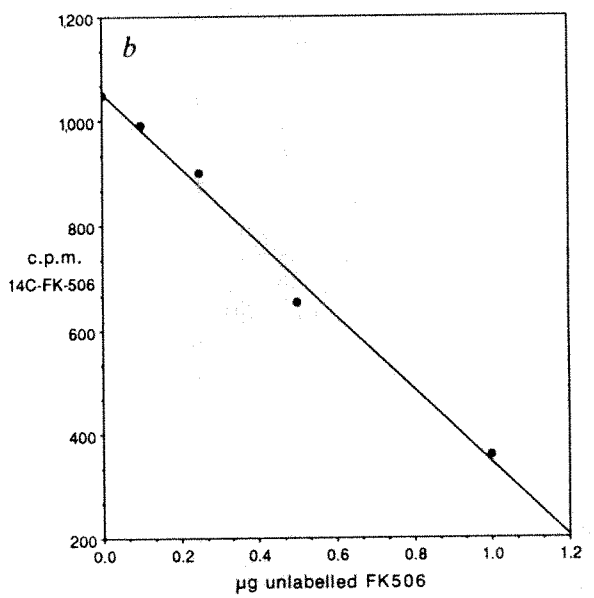

FIG. 3 *a*, Linear binding of 32-[1 − ^{14}C]-FK506 (Fig. 1,*4*) to increasing amounts of the bovine FKBP; *b*, titration with unlabelled FK506 (Fig. 1,*1*).

METHODS. Increasing amounts of bovine FKBP (63, 126 and 252 ng) were mixed with 1 μg of *4* (Fig. 1; 2.5 × 10^{6} c.p.m. μg^{-1}) in a total vol of 100 μl. FKBP/*4* complexes were recovered by a Sephadex LH-20 partition assay[9]. Titration of FK506 binding to a constant amount of the FKBP was performed by addition of 0.1, 0.25, 0.5 and 1.0 μg unlabelled FK506 to the *4*/FKBP reaction mixture, which resulted in a proportional displacement of radioligand from the complex.

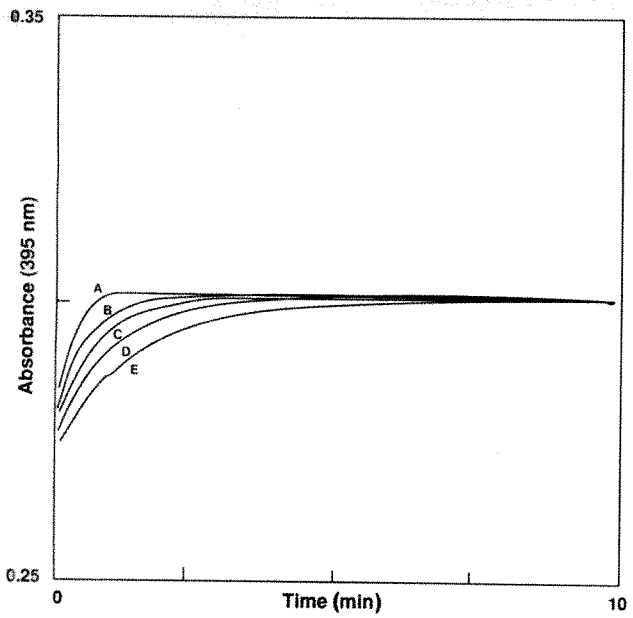

FIG. 4 Isomerase activity of human FKBP and its inhibition by FK506. *Cis–trans* isomerization of succinyl-Ala-Ala-Pro-Phe-4-nitroanilide (27 μM final concentration) was measured in a coupled assay with chymotrypsin, which hydrolyses the anilide bond in the *trans* (but not *cis*) isomer of the alanyl-prolyl containing peptide[12]. The test peptide was preincubated with (*a*) or without (*e*) 0.67 nM FKBP at 10°C and the reaction initiated by addition of chymotrypsin (27 μM final concentration). Reactions were in 100 mM Tris-HCl (pH 8.0) and the hydrolysis of the 4-nitroanilide in the *trans* isomer of the peptide substrate was monitored at 395 nm with a Kontron Uvicon 860 spectrophotometer. FK506 at final concentrations of 27 nM (*b*), 54 nM (*c*), and 270 nM (*d*) resulted in increasing levels of inhibition. Whereas 5 μM FK506 resulted in complete inhibition of enzyme activity, 5 μM CsA had no observable effect.

binding was also shown with affinity matrix-purified FKBP and cyclophilin by equilibrium exchange drug-binding assays. Analogously, in affinity matrix-drug elution experiments, the FKBP was not eluted from the FK506 matrix by CsA (100 ug ml^{-1}) and cyclophilin was not eluted from the CsA matrix by FK506 (500 μg ml^{-1}). In contrast to these findings, rapamycin (Fig. 1;*5*), an immunosuppressive macrolide antibiotic structurally related to FK506 (refs 15,16), readily displaced FKBP from the FK506 affinity matrix, providing further evidence of the specificity of this protein for structures related to FK506.

The similar immunosuppressive properties of FK506 and CsA and the presence of an α-keto (homo)proline amide linkage within the structures of FK506 and rapamycin suggested the possibility that the FKBP could catalyse the interconversion of proline rotamers. Accordingly, the assay of Fischer *et al.*[12] was used to test this hypothesis. In the presence of 0.67 nM human FKBP, the rate of *cis–trans* alanyl-prolyl isomerization of succinyl-Ala-Pro-Phe-4-nitroanilide was significantly increased. In a parallel experiment under identical conditions, a 10–20-fold lower concentration of cyclophilin was sufficient to achieve a comparable level of catalysis[12]. Addition of 5 μM FK506 completely inhibited the isomerase activity of the FKBP, whereas CsA (5 μM) had no effect. Similarly, FK506 was shown to have no effect on the isomerase activity of cylophilin (R. E. Handschumacher, personal communication). Experiments with concentrations of FK506 in the range of 27–270 nM showed partial inhibition of the isomerase activity and suggest a K_i of approximately 50 nM (Fig. 4).

The discovery that the CsA receptor cyclophilin functions as an isomerase raised the possibility that the recognition, or perhaps the actual isomerization, or proline-containing epitopes may be relevant to the regulation of intracellular signalling events in T cell activation[12,13]. The findings reported here support this proposal. Two immunosuppressive agents with no structural similarity bind to different proteins (immunophilins) that share a common enzymatic property. Each isomerase is inhibited by its respective ligand and these ligands do not exhibit cross inhibition. The apparent structural difference between the FKBP and cylophilin may reflect the existence of a spectrum of structurally distinct isomerases which may include the *ninaA* gene product[17,18] and a *Neurospora* mitochondrial protein[19], two recently described cyclophilin homologues. We suggest that proteins of the isomerase (rotamase) class may be components of a biochemical regulatory network that is important for T cell activation and other metabolic processes. □

Note added in proof: Complementary DNA that encodes the FKBP has been cloned from Jurkat cells (R. F. Standaert, G. L. Verdine and S.L.S.). From the deduced amino-acid sequence, the molecular weight of FKBP is calculated to be 11,805.

Characterization of a homologue of bithorax-complex genes in the leech *Hirudo medicinalis*

Joanna W. Wysocka-Diller, Gabriel O. Aisemberg, Miriam Baumgarten, Michael Levine & Eduardo R. Macagno*

Department of Biological Sciences, Columbia University, New York, New York 10027, USA

WE report the isolation and characterization of the *Hirudo medicinalis* homoeobox gene *Lox2*. Sequence analysis shows that it contains a region that has homology to *Drosophila* and vertebrate homoeodomains of the *Antennapedia* class. In addition, *Lox2* shares homology with sequences in the bithorax complex *Ultrabithorax* (*Ubx*) and *abdominalA* (*abdA*) genes in a region adjacent to the C-terminus of the homoeodomain. Whole mount *in situ* hybridization of embryos of various ages demonstrates that during early development this gene has temporally and spatially restricted patterns of expression that resemble those of the homoeotic genes

* To whom correspondence should be addressed.

of the *Drosophila* bithorax complex and of many vertebrate homoeobox genes. The largest accumulation of transcripts was seen in the posterior two-thirds of the developing leech central nervous system in 7–14-day-old embryos. Adult leeches also express *Lox2*. We propose that in *Hirudo*, *Lox2* represents the ancestral gene of the *Ubx* and *abdA* genes of the bithorax complex of *Drosophila*.

The *Lox2* gene fragment of *Hirudo medicinalis* was isolated by low stringency hybridization to a probe derived from the *Sex combs reduced* (*Scr*) gene of *Drosophila*. The *Lox2* fragment was found to contain, within a 354-base pair (bp) open reading frame (Fig. 1*a*), a 180 bp sequence that showed extensive homology with the homoeoboxes of the *Antennapedia* (*Antp*) class, particularly to those present in the *Drosophila* genes *Antp* (ref. 1) (52/60 amino-acid identity), *abdA* (ref. 2) (52/60) and *Ubx* (ref. 3) (51/60); the murine genes *Hox*1.1 (ref. 4) (52/60), *Hox2.2* (ref. 5) (51/60) and *Hox2.3* (ref. 6) (52/60); the human genes *HOX1A* (51/60) and *HOX2C* (ref. 7) (51/60); and the *Xenopus* gene *XlHbox2* (ref. 8) (52/60), among others. In addition, the region of homology between *Lox2* and *Ubx* was found to extend 33 nucleotides beyond the 3′-end of the homoeobox. In this stretch, 9 of the 11 resultant amino-acid residues are identical in *Lox2* and *Ubx* products and a tenth residue shows a conservative change (Fig. 1*b*). The homology between *Lox2* and *abdA* products is lower but significant in this region (4 amino-acid identities and 4 conservative changes; F. Karch, W. Bender and B. Weiffenbach, personal communication). Also, a search through the entire translated Genbank database (6/89) for homology to the *Lox2* 11 residue peptide selected the corresponding *Ubx* peptide as the best match; lesser matches were found (6/11 amino acid identity or less), but only to proteins with no other homology to either *Ubx* or *Lox2* products. The homology between these genes ends just at the beginning of a repetitive region of the *Ubx* protein that is rich in glutamine. The C-terminal end of the *Lox2* protein is rich in serine and threonine and might be phosphorylated *in vivo*. These regions could, therefore, be transcriptional activation domains[9]. A splice acceptor sequence located upstream of the *Ubx* and *abdA* homoeoboxes is also present in the leech gene (Fig. 1*a*). The similarities presented here lead us to propose that *Lox2* is the leech homologue of a bithorax-complex (*BX*-C) gene or genes.

To confirm this homology, we studied the expression of *Lox2* by *in situ* hybridization of whole-mount preparations of embryos. Embryogenesis in *Hirudo* takes ~30 days at 22–23 °C. Segment formation begins at 5–6 days, with ~6 segments clearly visible by the end of day six[10]. During the next four days, the remaining segments are added sequentially, from anterior to posterior, with the full complement of 32 segments present by day 10. Differentiation begins anteriorly at 6–7 days and also proceeds with an anterio-posterior temporal gradient. By day 13, most of the definitive tissues can be identified.

We did not detect any expression of *Lox2* in 5- or 6-day-old embryos. Evidence for the earliest expression, faint bands of medially positioned silver grains in the primordia of body segments 7 to 12, was observed in late 7-day-old embryos (data not shown). In 8-day-old embryos the signal was seen to extend further caudally, to about body segment 15, and to be the strongest in the segmental ganglia of the ventral nerve code (Fig. 2*a*). By day 9 of embryogenesis the signal extended from body segment 7 to about body segment 20 (Fig. 2*b*) and, by day 11, strong signals were present on body ganglia 7 to 21, with somewhat weaker signals on the tail ganglion (Fig. 2*c*). In addition, we detected two clusters of silver grains in the posterior margin of body ganglion 6 (Fig. 2*d*). Some signal above background was also detectable on the remainder of the germinal plate during these stages (Fig. 2*a–c*), but we could not assign it to any specific peripheral organs or tissues using this *in situ* hybridization technique. Expression of *Lox2* showed a relative decrease in the most posterior ganglia between days 11 and 14, by which time the strongest signal was found in the ganglia of body segments 7 to 14, with lighter signals more posteriorly (data not shown). We were not able to examine older embryos with this technique, but expression of *Lox2* in adult leeches has been detected by northern blot hybridization (data not shown), indicating a continued expression of this gene in later stages.

Comparison of the expression patterns of *Lox2* and the BX-C genes *Ubx* and *abdA* shows that they are all active early in development. Activation of *Lox2* coincides with the time of segment formation, and that of *Ubx*, for example, with the late syncytial blastoderm stage[11]. These genes continue to be expressed throughout development and into adulthood. A striking feature of the *Lox2* domain of expression is the stability of

FIG. 1 Partial sequence of *Lox2*. *a*, Nucleotide sequence and conceptual translation of the most 3′ exon of *Lox2*. The homoeobox is underlined and a splice site that has been identified by RNase mapping (data not shown) is indicated by an arrowhead. The coding region of *Lox2* ends at the underlined stop codon TGA. *b*, Comparison with the most 3′ exon of *Ubx*. Colons indicate identities; single dots, conservative changes. The *Ubx* homoeodomain is underlined.

METHODS. A *Hirudo* genomic library was constructed in the λ EMBL3 vector[16]. The library was screened at low stringency with a *Scr* *Sac*I–*Xba*I fragment containing the homoeobox[13]. Selected subfragments from a positive clone were subcloned into the plasmid pIBI31 (IBI) and into the phages M13mp18 and M13mp19 (ref. 17). The sequence was obtained according to the chain termination method[18], using a modified T7 phage DNA polymerase (USB Corp.).

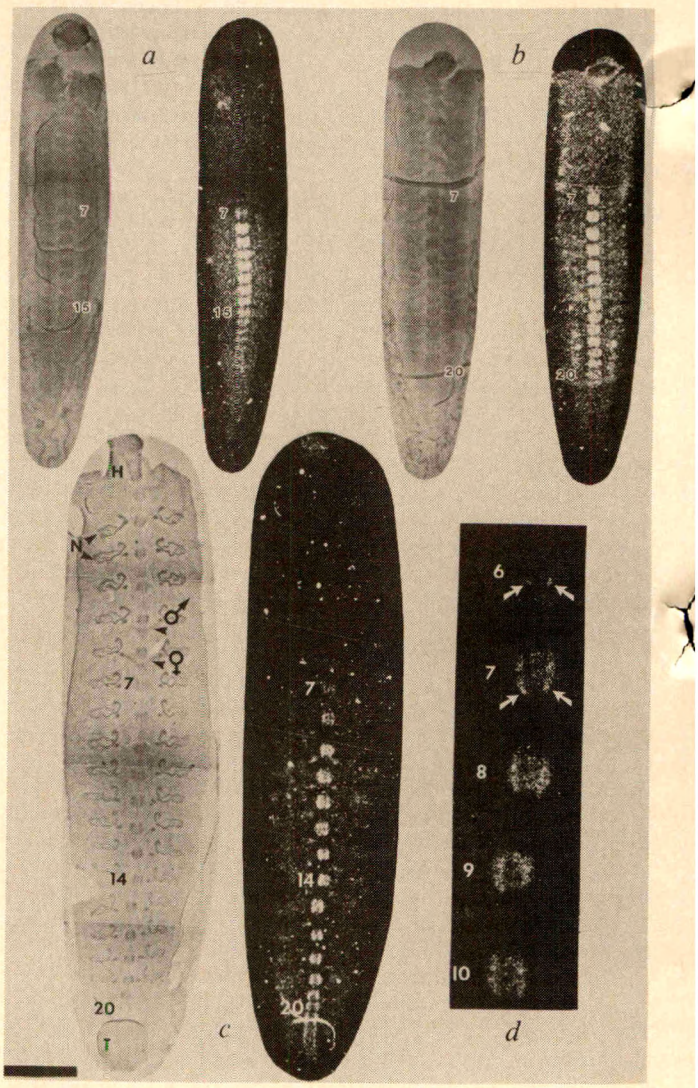

FIG. 2 Localization of *Lox2* transcripts in leech embryos. Dorsal views of whole mounts of embryos of different ages hybridized to ^{35}S-labelled riboprobes. The left side of each panel (*a*–*c*) shows a bright-field micrograph of an embryo and the right side its corresponding dark-field micrograph. The numbers on the pictures indicate the position of some of the twenty-one body ganglia. Anterior is at the top. *a*, Late 8-day-old embryo. The medial region is occupied by the ventral nerve cord, with ganglia that are more differentiated in anterior segments. Some body segments posterior to body segment 16 can be discerned but the tail segments have not yet formed. The highest *Lox2* expression is in the ventral nerve cord from body segment 7 to body segment 15. In this and the following embryos, a diffuse signal can be seen outside the CNS in the segments that express *Lox2* and a weak hybridization is also distinguishable in the primordia of a few, more posterior ganglia. *b*, A 9-day-old embryo. All body segments are present by this age and the tail segments are just beginning to differentiate. Strong *Lox2* expression is present in body ganglia 7 to 20. *c*, An 11-day-old embryo. The neuromeres that contribute to the head ganglion (H) have fused, whereas those that make up the tail ganglion (T) are in the process of fusing. The primordia of the male and female genitalia and the bilateral nephridia (N) can be seen. The highest level of *Lox2* transcript accumulation is in the body ganglia 8 to 19. *d*, Dark-field micrograph showing at higher magnification body ganglia 6 to 10 of a 10-day-old embryo probed with *Lox2*. Arrows indicate posterior cell clusters expressing *Lox2* in ganglia 6 and 7. Clusters in the same position seem to express *Lox2* in more posterior ganglia.
METHODS. Germinal plates and cryptolarvae of dissected leech embryos were fixed in paraformaldehyde, rinsed several times with PBS and permeabilized with pronase[19]. The embryos, mounted on polylysine-coated slides, were re-fixed and acetylated[20]. Finally, slides were rinsed with PBS and dried at room temperature. RNA probes labelled with ^{35}S were synthesized from a plasmid containing a *Lox2 Eco*RI-*Cla*I fragment[21] (see Fig. 1). A probe with the most 3′ 414 nucleotides including only the last quarter of the homoeobox was used with identical results (data not shown). Each embryo was covered with 15μl of hybridization solution (50% formamide, 10% dextran sulphate, 10 mM DTT, 0.3 M, NaCl, 10 mM Tris-HCl, 10 mM sodium phosphate buffer, pH 6.8, 5 mM EDTA, 1x Denhardt's solution and 0.2 mg ml^{-1} transfer RNA) containing ~2 ng (2×10^5 c.p.m.) of the appropriate riboprobe (adjusted to ~100-bases long by limited alkaline hydrolysis) and incubated overnight at 60 °C. The slides were then washed with 2 changes of low-salt buffer[22] for 30 min at 65 °C and treated with RNase A (20μg ml^{-1}) in NTE buffer (0.5 M NaCl, 10 mM Tris-HCl and 1 mM EDTA) for 1.5 hr at 37 °C. The slides were rinsed again briefly with NTE and washed overnight at 55 °C with several changes of 50% formamide, 2 × SSC, 100 mM 2-mercaptoethanol, then rinsed several times in 1 × SSC, dried and dipped in Kodak NTB emulsion for autoradiography and exposed for 8 days. After development the embryos were counter stained with Giemsa and mounted with Permount.

its anterior boundary as compared with the dynamic nature of its less sharply defined posterior limit, which shifts caudally at first and then recedes, as the more posterior segments are formed and differentiate. These temporal changes aside, the domain of expression of *Lox2* extends over at least 8 or more segments during the period between 8 and 14 days of development. The embryonic domain of strong *Ubx* expression also changes with time: it is restricted to parasegment (PS) 6 in the cellular blastoderm and in the late embryo, but extends from PS6 to PS12 between these stages; weaker expression in PS5 and PS13 is seen during this time[11–13]. Finally, *Lox2* is expressed most strongly in the central nervous system, at least in the embryonic stages we have studied. By contrast, *Ubx* is expressed strongly in epidermal and mesodermal tissues as well as the nervous system, at least in early stages.

The identification of a putative BX-C gene cognate in the leech contradicts an important aspect of previous models for the evolution of the homoeotic genes of the fly[14,15]. These models are based on the idea that insects are derived from a myriapod-like ancestor with very similar trunk (thoracic + abdominal) segments. They presume that BX-C genes such as *Ubx* and *abdA* arose later in evolution, by the duplication of an *Antp*-like gene, to suppress the action of anterior homoeotic genes within the presumptive abdomen. The finding of *Lox2* in the leech indicates that a BX-C gene homologue was present much earlier than these models propose. As the *Ubx* and *abdA* homoeoboxes are more homologous to each other (56/60 amino-acid identity) than either of them is to *Lox2*, it is possible than an ancestor of *Lox2* gave rise to both fly genes only after the split of arthropods and annelids. The higher homology found between *Lox2* and *Ubx* also indicates that *Ubx* is the fly gene most closely related to this proposed ancestral gene. Also, it has been proposed that *Antp*, *Ubx* and *abdA* arose from a single gene by duplication during arthropod evolution[15]. It would be interesting to know whether there is an *Antp* homologue in the leech in addition to *Lox2*, or whether this gene is the only one that specifies positional information in the central and posterior body segments. □

Fluorescence energy transfer shows that the four-way DNA junction is a right-handed cross of antiparallel molecules

THE four-way junction between DNA helices is the central intermediate in recombination[1–10], and the manner of its interaction with resolvase enzymes can determine the genetic outcome of the process. A knowledge of its structure is a prerequisite to understanding the interaction with proteins, and there has been recent progress[11–14]. Here we use fluorescence energy transfer to determine the relative distances between the ends of a small DNA junction, and hence the path of the strands. Our results are consistent with the geometry of an 'X'. The interconnected helices are juxtaposed so that the continuous strands of each helix generate an antiparallel alignment, and the two interchanged strands do not cross at the centre. The acute angle of the X structure is defined by a right-handed rotation of the helical axes about the axis perpendicular to the X plane, as viewed from the centre of the X.

The *in vitro* construction of defined DNA junctions[11,15–17] has been essential to the understanding of the structure of the four-way junction. The structure introduces a sharp bend in the DNA[11]. Using a technique related to that of Cooper and Hagerman[12], we studied the configuration of a series of junctions[13] and proposed a general model for the helical junction—the stacked X structure. The molecular geometry of the X at the junction is formed by the pairwise stacking of the helical arms, resulting in quasi-continuous helices. Helix–helix stacking was first proposed by Sigal and Alberts[18]. The symmetry of our structure is consistent with results of hydroxyl radical probing of synthetic junctions[14]. The choice of stacking partners is governed by the sequence at the junction, and the pattern of cleavage by phage resolvase enzymes is dependent on the isomeric form adopted for a given DNA sequence[13,19]. In the absence of metal ions, junctions of any sequence adopt a structure close to square-planar, in which the four arms are unstacked and maximally extended.

Four stereochemical arrangements of the stacked X structure are possible (Fig. 1). Gel electrophoresis experiments indicated that a non-crossed structure was correct[13], but this conclusion rested on assumptions about the electrophoretic mobility of DNA. Here we have used an independent approach, employing fluorescence energy transfer techniques to measure relative end-to-end distances in the junction. The stacked X-model predicts that two of the end-to-end distances from the possible six will be shorter than the others, and identification of these will distinguish between crossed and non-crossed structures. Two fluorescent dyes attached to a macromolecule can exhibit an overlap of emission (donor) and excitation (acceptor) frequencies, when energy transfer then becomes possible from donor to acceptor. The transfer is dependent on the distance between the donor and acceptor (in the size range from 30 to 70 Å); the efficiency of transfer (E) is given by $E \propto (1+(R/R_0)^6)^{-1}$, where R is the distance between the dyes, and R_0 is the distance where the efficiency of transfer is 0.5 (refs 20, 21).

We attached fluorescein and tetramethyl rhodamine to the 5′ ends of selected oligonucleotides used for the assembly of junctions to investigate the energy transfer across the six possible end-to-end distances, each of which could be studied in both directions. These experiments were carried out for a variety of arm lengths, but the best results were obtained using junctions constructed from oligonucleotides of 34 bases, giving junctions of arm length 17 base pairs (see below). As the strength of a dipole–dipole interaction is dependent on orientation as well as distance, at least one of the dyes had to be relatively mobile. Hence we used a C_6 linker to attach the dye to the DNA. Subsequent measurements of fluorescence anisotropy indicated that there was some interaction between the dyes and the ends of the arms, so we included a 5′ CpC on each arm to maintain a constant environment for the dyes. As we can unfold the junction by the removal of ions[13], the energy transfer can be measured before and after the addition of magnesium while keeping all other factors constant.

The junction sequences chosen for these studies were essentially those of junctions 1 and 2 (ref. 13), previously shown to have different isomeric conformations. The central sequences are given in Fig. 2*a*. The ratios of fluorescence energy transfer for junctions 1 and 2 with and without the addition of 5 mM magnesium ions are shown in Fig. 2*b*. For junction 2, the largest increase in energy transfer upon addition of Mg^{2+} was for the doubly labelled arms B–H or R–X. By contrast, the results for junction 1, with the opposite isomeric configuration[13], show the largest increase for the B–X and H–R labelled arms (Fig. 2*b*). Both these results verify the conclusions of our earlier gel electrophoresis experiments[13]. In addition, the relative energy

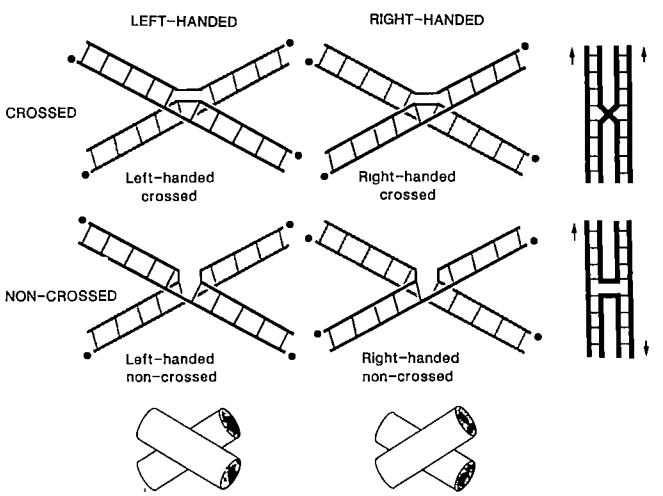

FIG. 1 Possible topology of strands and helices in the stacked X structure of the four-way junction The strands can be drawn as non-crossed or crossed, generating an antiparallel or parallel alignment of the sequences respectively (indicated by the arrows) Because of the non-planarity of the X, the helices can cross in either a right-handed or a left-handed form (the convention for the handedness indicated is based on the definition of dihedral angles[24]) The helices at the back are stippled The combination of these variables generates four possible structures. The 5′ termini of strands are indicated by filled circles, and are designated in such a way that all interconversions can be carried out in the plane of the page

transfer in the presence of Mg^{2+} between all the doubly labelled permutations of the derivatized junction 1, and similarly for junction 2, corroborate these results. The relative energy transfer, and its increase by Mg^{2+}, are consistent with only the non-crossed structure. Using estimates of the optical parameters of the dyes, we can calculate the distance between the shortest ends of the stacked X to be $\sim 1.5\ R_0$. Using R_0 values from the literature[22], this gives $R = 55$–65 Å, which is a reasonable estimate if the acute angle is 60°. We stress, however, that this calculation includes several parameters that are not yet accurately determined for our experimental conditions, and therefore is subject to error. The strength of our conclusions about the stereochemistry of the four-way junction rests upon the comparison of the extent of energy transfer within a large group of nearly identical molecules, not upon a calculated value of R. The energy transfer experiments thus confirm all the details of our proposed model for the DNA junction. The observation of just two short distances is consistent with the X shape, and in the absence of cation these distances lengthen. The stacking partners are dependent on the sequence at the centre of the junction, exactly as we have described, and, most important, our results confirm that the X structure approximates most closely to the non-crossed, or anti-parallel, structure.

Can these results be translated into a structure that is stereochemically reasonable? Exploration of the four potential X structures (Fig. 1) using DNA models shows one arrangement to be particularly satisfactory, in that it avoids clashes between the deoxyribophosphate backbones in the vicinity of the point of joining. This is the right-handed cross, with non-crossed strands (Fig. 3). If the two long arms of the X are orientated at ~60° to each other, the strands of one helix are aligned with the grooves of the other, and vice versa. Any other arrangement of the helices leads to unfavourable clashes between the backbones.

The stereochemical analysis predicts that the stacked X structure should be right-handed. Inspection of the right-handed, non-crossed model for junction 2 reveals that the phosphate situated 18 bases from the junction on the 5′ strand of arm B is closest to the H arm. We therefore prepared a series of labelled junctions in which fluorescein was attached to this position on arm B. In this series, we varied the length of the H arm (while maintaining the 5′ CpC sequence) between 12 and 21 base pairs,

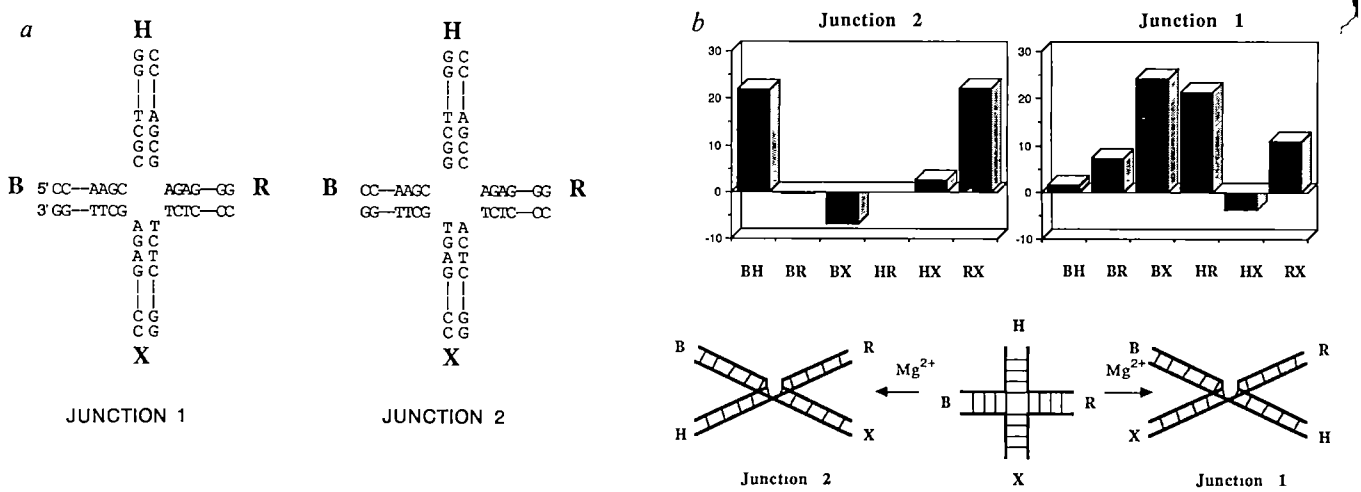

FIG 2 Magnesium-induced changes in fluorescence energy transfer ratios measured for two junctions of different isomeric structure *a*, Central sequences of the junctions used in these studies The sequences of the central 15 base pairs of each arm were identical to those of junctions 1 and 2 used in gel electrophoresis experiments[13]. The arms are labelled B, H, R and X The junctions differ only in the reversal of two central base pairs, and previous experiments have indicated that this is sufficient to induce a change in stacking partners Thus in junction 1, the B arm is stacked to form a co-linear helix with the H arm, whereas in junction 2, the B and X arms are stacked[13] The full sequences of the four oligonucleotides comprising junction 2 are CCTCCGTCCTAGCAAGCGGCTGCTACCGGAAGGG, CCCTTCCGGTAGCAGCCAGAGCGGTGGTTGAAGG, CCTTCAACCACCGCTCTACTCAACTGCAGTCTGG and CCAGACTGCAGTTGAGTGCTTGCTAGGACGGAGG *b*, Changes in fluorescent energy transfer on addition of magnesium ions. The emission spectra between 500 and 525 nm of the doubly labelled junctions are due only to the emission of the fluorescein label and thus the fluorescein contribution to the spectrum can be subtracted, leaving only a rhodamine spectrum containing emission which is due both to direct excitation and to energy transfer from fluorescein The following values were then selected from the excitation spectrum and the fluorescein-subtracted emission spectrum $F_{490/600}$ (emission at 600 nm with excitation at 490 nm), contains both direct excitation ($F^{dir}_{490/600}$) and energy transfer ($F^{tran}_{490/600}$), $F_{565/600}$, contains direct rhodamine excitation only The ratio R is thus measured

$$R = F_{490/600}/F_{565/600} = (F^{dir}_{490/600} + F^{tran}_{490/600})/F^{dir}_{565/600} = R^{490/600}_{565/600} + F^{tran}_{490/600}/F^{dir}_{565/600}$$

The ratio $R^{490/600}_{565/600}$ is constant and only involves the absorption coefficients As this is relatively small, R measures the ratio of the fluorescence due to energy transfer to the direct fluorescence of rhodamine These values were measured in the presence and absence of magnesium ions, and their difference is presented graphically When this was measured for a doubly labelled isomer with both permutations of labels, an average is shown As there is a linear relation between the absorption and fluorescence of rhodamine for all samples, this ratio normalizes the extent of transfer for all the samples, and the ratio is proportional to the per cent transfer Only the optical constants of the dyes determine the proportionality constant The schematic drawings below the graphs for junctions 2 and 1 illustrate the interpretation of the fluorescent energy transfer changes. For junction 2, the distances that shorten on magnesium-induced folding, causing increased transfer, were B–H and R–X, indicating a non-crossed structure with co-linear B on X and H on R arms For junction 1, the shortened distances are B–X and H–R, indicating a non-crossed structure with co-linear B on H and R on X arms METHODS Preparation of dye-conjugated junctions Oligonucleotides were synthesized on an Applied Biosystems 381A DNA synthesizer using β-cyanoethyl phosphoramidite chemistry[25,26] A C_6 linker with a free amine group was incorporated at the 5′ end of the molecule by a final coupling with *N*-trifluoracetal-2-aminohexyl(2-methoxy)-*N,N*-diisopropylamino phosphite[27] (Applied Biosystems) Crude oligonucleotides were purified on an anion exchange column (Nucleogen, Diagen), followed by a C_8 reverse-phase column (Aquapore, Applied Biosystems) Each oligonucleotide (one absorbance unit at 258 nm) was reacted with 3 μl of 50 mg ml^{-1} of the *N*-hydroxy-succinimide ester of tetramethylrhodamine (Applied Biosystems) in dimethylsulphoxide with 0 2 M carbonate buffer (pH 9 5) to give a total volume of 15 μl for 4–12 h at room temperature in the dark, and, in a separate reaction, with 20 μl of 10 mg ml^{-1} fluorescein isothiocyanate (Sigma) in dimethylformamide with 0 3 M carbonate buffer (pH 9 5) for 4–12 h at room temperature in the dark After separation of unreacted dyes on Sephadex G25, conjugated oligonucleotides were purified by electrophoresis in a 20% polyacrylamide gel containing 7 M urea In order to construct junctions, oligonucleotide solutions (0 04 absorbance units at 258 nm) were hybridized in appropriate combinations in 2 mM $MgCl_2$, 3×SSC at 65 °C, and slowly cooled to 10 °C Junctions were purified by electrophoresis in 8% polyacrylamide gels in 90 mM Tris-borate (pH 8 3), 2 mM $MgCl_2$, with circulating buffer Junctions were excised, electroeluted and ethanol-precipitated Fluorescence spectroscopy Fluorescence spectra were recorded using an SLM 8000S fluorimeter Excitation and emission spectra were corrected for lamp variation and instrumentation factors, and polarization artefacts were eliminated using magic angle conditions. Data were acquired and analysed with a DEC-LSI/23 computer Dye concentrations were generally between 50 and 150 nM, per cent labelling was estimated from absorption spectra to be constant at 100% for all the samples The absorption spectra of fluorescein, rhodamine and DNA were linearly related among all the samples and the excitation spectrum maxima that were due only to directly excited rhodamine were linearly related to the corresponding absorption spectra The assembled dye-labelled junctions were dissolved in 90 mM Tris-borate (pH 8 3), 0 1 mM EDTA, for spectroscopy, conditions were identical to those used in gel electrophoresis experiments[13] Magnesium chloride was added from a concentrated stock solution

and attached rhodamine to the 5′ ends. This has the effect, shown diagramatically in Fig. 4*a*, of 'walking' the rhodamine dye around the H arm helix. Consideration of the right-handed model suggests that the two dyes should be closest when the rhodamine is attached to base 16, so energy transfer should exhibit a maximum for this junction. For a left-handed cross the situation is reversed, with these phosphates located on opposite sides of the helix. The results are presented graphically in Fig. 4*b*. The energy transfer exhibited a maximum when the rhodamine was attached to phosphates 15 to 16, in agreement with the prediction based on the right-handed structure. We therefore conclude that the four-way junction is indeed a right-handed, non-crossed structure.

A number of biological implications follow from the structure we have deduced for the four-way junction. Geneticists are accustomed to drawing the Holliday junction with the homologous DNA molecules aligned in a parallel manner, but this does not seem to be the natural energetic preference of DNA. Accessory proteins may influence the structure of recombination intermediates in the cell, but if that is so, then we have identified an important role for them. Antiparallel Holliday junctions would have consequences for branch migration. The 60° cross implies that the point of contact between homologous DNA molecules is limited to a very small region around the junction. Antiparallel junctions complicate synapsis between homologous sequences, but not fatally, given the long-range flexibility of DNA molecules. Antiparallel orientation might simplify certain site-specific recombination processes: for example, the topology of integration and excision of phage λ becomes symmetrical in both directions if the junction is drawn in the non-crossed form[23]. As physical information is available directly from fluorescence energy transfer experiments on nucleic acids, the technique might be applied profitably to related systems, such as the analysis of curved DNA in solution. □

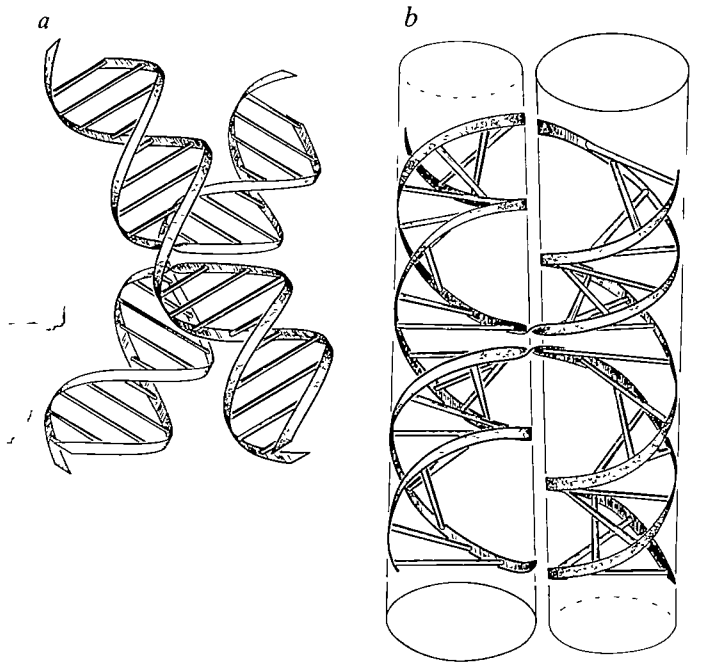

FIG 3 A non-crossed, right-handed structure avoids unfavourable phosphate–phosphate interactions *a* and *b*, Front and side views of the structure this relative orientation of the two quasi-continuous helices, it can be seen that the continuous strands are accommodated in the major groove of the opposite helix, at the position closest to the centre of the junction This point may be appreciated most readily by examination of two simple DNA models inclined correctly Molecular mechanics calculations (E v K, D M J L and S.D , manuscript in preparation) indicate that the non-crossed right-handed structure does not violate stereochemical principles, and a related packing of helices has recently been found in a crystal of a double-stranded DNA oligonucleotide (D. Moras, personal communication)

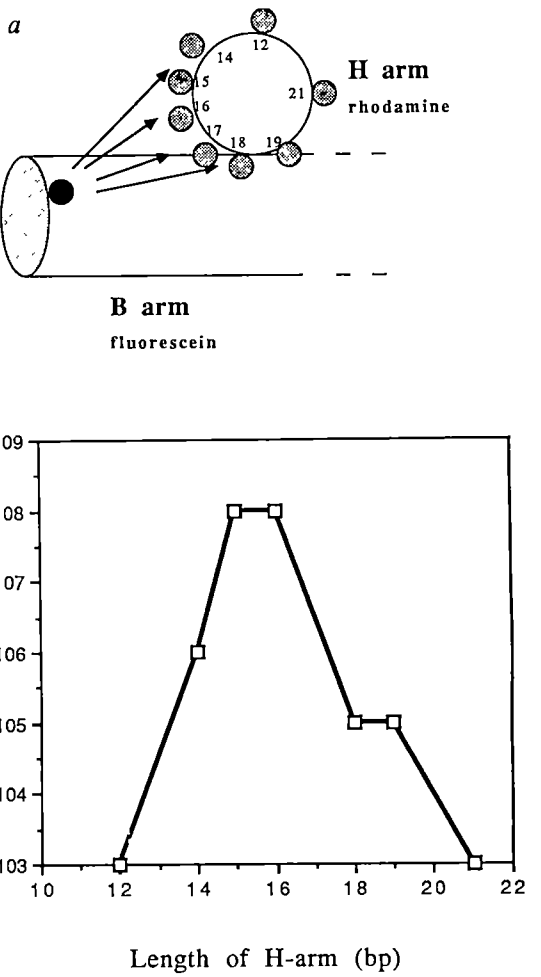

FIG 4 Fluorescence energy transfer indicates that the helices cross in a right-handed manner. Junctions based on the central sequence of junction 2 were constructed with arm lengths of B (18 base pairs), H (12 to 21 base pairs), R and X (both 15 base pairs). These were prepared with dye-conjugated oligonucleotides as before, with fluorescein attached to the 5′ end of the B arm, and rhodamine on the H arm *a*, Schematic to illustrate the relative dispositions of the B arm and H arm dyes for a right-handed cross Model building indicates that the smallest dye–dye distance should occur when the H arm is ~16 base pairs. *b*, Energy transfer as a function of the position of rhodamine attachment Plot is of fluorescence transfer ratio against the length of the H arm, for the junctions in the presence of 5 mM magnesium ion The transfer is clearly maximal for an H-arm length of 15–16 base pairs, in agreement with the prediction of a right-handed X structure. Equivalent results were obtained (data not shown) for the reverse direction, $H_{(fluorescein)} - B_{(rhodamine)}$.

CORRECTION

Correlation between the anaesthetic effect of halothane and saturable binding in brain

A.S. Evers, B.A. Berkowitz & D. A. d'Avignon

Nature **328**, 157–160 (1987).

IN a previous issue of *Nature*, we reported that the anaesthetic effect of halothane correlated with the occupancy of a saturable chemical environment in rat brain[1]. We have extended these observations by examining the equilibration of halothane between cerebral cortical brain slices and anaesthetic-equilibrated buffer, an experimental paradigm in which whole-animal physiology cannot influence brain anaesthetic uptake. These studies showed that brain-slice halothane concentration was, with only minor deviation, a linear function of buffer concentration. This discrepancy between *in vitro* and *in vivo* equilibration studies led us to re-examine *in vivo* uptake of anaesthetic by simultaneously measuring brain and blood halothane concentrations in rats anaesthetized with various inspired concentrations of halothane. These studies showed higher brain and plasma halothane concentrations than those we originally reported (Fig. 1): this results from improved calibration technique and possibly, in plasma, from reduced loss of halothane by volatilization during sample preparation. Brain and blood halothane concentrations were seen to rise in parallel as a function of inspired concentration, and the brain/blood halothane ratio (inset of Fig. 1) was constant over the entire inspired concentration range studied. The observed nonlinear relationship between inspired and blood halothane concentrations was not the result of blood saturation, as *in vitro* halothane/gas partition coefficients (37 °C) were the same (2.78±0.08) at 1% (v/v) and 3% halothane. These data indicate that anaesthetic-induced depression of halothane uptake into blood is predominantly responsible for the apparent saturation of brain observed *in vivo*; the apparent saturation reported earlier[1] is not the result of a limited number of binding sites in brain.

We have also reported the existence of two chemical environments for halothane (and for other volatile anaesthetics) in brain[2], as defined by ^{19}F-NMR spin–spin relaxation behaviour[1]. The two environments are differentially occupied as a function of both inspired anaesthetic concentration and duration of

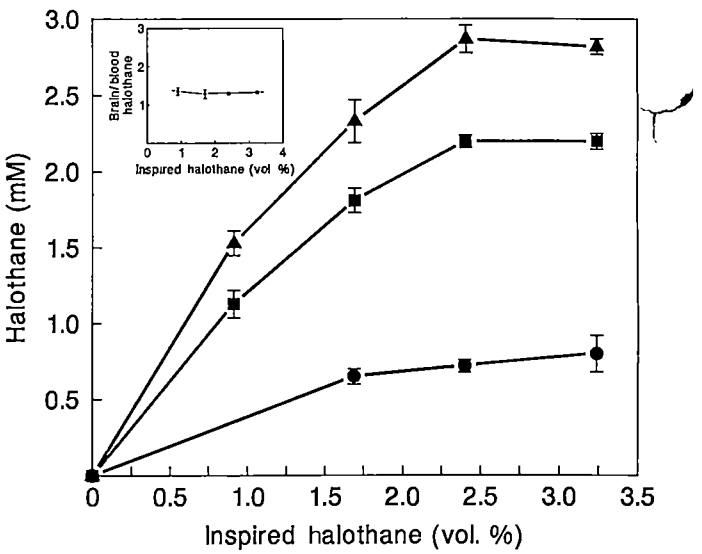

FIG. 1 Brain and blood halothane concentrations simultaneously measured in spontaneously ventilating rats. Rats were allowed to breathe various inspired concentrations of halothane (measured by gas chromatography) for 1 hour Arterial blood was withdrawn and the animals were decapitated. Blood halothane concentrations (■) were measured by gas chromatography, and brain halothane concentrations (▲) were measured both by gas chromatography and by NMR (ref. 1). Gas chromatography and NMR measurements of brain halothane gave identical results In parallel experiments, plasma halothane concentrations (●) were measured by gas chromatography. Note that plasma halothane concentrations were reasonably well predicted by our *in vitro* measurement of the rat plasma/gas partition coefficient of ~1 3 The inset shows the brain/blood halothane concentration ratio plotted as a function of inspired concentration. All data are the mean ± s d. of 3–6 determinations.

delivery; occupancy of one of these environments (that with a short T_2) correlates with the anaesthetic effect of halothane. In light of our recent findings, it is apparent that occupancy by halothane of the short T_2 environment scales with total brain concentration; this environment is not saturable over the range of concentrations attainable *in vivo*. The other (long T_2) halothane environment represents an increasing proportion of total brain halothane concentration as a function of increasing inspired concentration and duration of anaesthetic administration. The basis for differential occupancy of the two halothane environments is not known, but could be the result of time- and concentration-dependence of either anaesthetic-induced membrane disruption[3] (producing the long T_2) or changes in regional blood-flow distribution (for example, to white and grey matter). Although the physical chemical basis for the ^{19}F-NMR relaxation behaviour of anaesthetics in brain remains unknown, this relaxation behaviour is likely to be pharmacologically relevant, as evidenced by the strong correlation between volatile anaesthetic potency and ^{19}F-NMR T_2 values in brain[2]. We are continuing to investigate the structural basis for and the pharmacological relevance of anaesthetic ^{19}F relaxation behaviour in brain. This letter is submitted to correct the record as regards our previous report[1]. □

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously.

Nature is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature*'s staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully.

Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words.

CATEGORIES OF PAPER

Review Articles survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications.

Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

News and Views articles are intended to inform non-specialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules.

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only. Four copies are required, each accompanied by lettered artwork. Four copies of half-tones should be included. Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered. Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such. Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers.

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters. Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes.

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number. Original artwork should be unlettered. Ideally, no figure should be larger than 28 by 22 cm. Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome. Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published.

Colour Artwork. A charge of £500 a page is made for 4-colour figures. Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained.

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible. The figure should be described first, then, briefly, the method. Reference to a method described elsewhere is preferable to a full description. Methods should not be described in detail in the text.

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends. Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited. All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate). Text should not be included in the reference list. References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65). The first and last page numbers should be cited. Reference to books should clearly indicate the publisher and the date and place of publication.

Abbreviations, symbols, units and Greek letters should be identified the first time they are used. Acronyms should be avoided as much as possible and, when used, defined. Editors will shorten words if necessary. In case of doubt, SI units should be used.

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named.

Acknowledgements should be brief. Grant numbers and contribution numbers are not allowed.

Submission. *All manuscripts may be submitted to either London or Washington. They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT).*

THE LATEST ON ALZHEIMER'S DISEASE RESEARCH

Eleven 30-45 min. presentations with dialogues involving key scientists on current research directions, available on Videotape.

INCLUDES:

PROTEIN-NUCLEIC ACID INTERACTION

Volume 10 Topics in Molecular and Structural Biology

Edited by W. Saenger and U. Heinemann.

The book contains articles highlighting the rapidly evolving field of protein-nucleic acid interactions. Individual chapters demonstrate the diversity of biological systems to which protein-nucleic recognition is of central importance
There are chapters on the interaction of small proteins with DNA and RNA as well as on chromatin organisation. Care has been taken to include accounts of many different experimental approaches to studying the subject All articles are written by scientists actively involved in the research they describe and considered experts in their respective research areas The book is well-illustrated and contains extensive bibliographic information to provide easy access to the original literature

July 1989 £40.00 214pp 234 x 156mm 0-333-45321-2

This book is available from your usual bookseller or from.

Computers in behavioural research

L. P. J. J. Noldus, E. L. H. M. van de Loo and P. H. A. Timmers

Event recording methods have evolved from stopwatches and checksheets, through chart recorders and dedicated electronic event recorders, to flexible systems based on off-the-shelf microcomputers.

MANY types of behavioural research, in disciplines ranging from ethology and behavioural ecology to pharmacology, toxicology, psychology and psychiatry, require accurate timing and recording of sequences of events. For a long time, the most common recording method consisted of timing with a stopwatch in combination with hand-written notes on a checksheet. Mechanical chart recorders, introduced in the 1960s, allowed more accurate timing of rapidly occurring streams of events. Consequently, observations could be of greater complexity with regard to the number of different events and subjects observed. However, as both methods involve considerable manual data processing, there exists an ongoing interest in electronic event recording systems. These offer two major advantages over earlier methods: they save time and they reduce the occurrence of errors because data do not have to be transcribed.

Over the past two decades, several types of electronic event recorders have been developed. These typically consist of a specially designed keyboard with a number of pushbuttons and/or switches, the state of which is internally scanned at very short time intervals. Most early types of event recorders encode observations on magnetic tape for later storage and analysis on a mini or mainframe computer. More recent types have battery-powered electronic memory, which allows operation away from a permanent data storage device and, thus, increases portability. Several event recorders have become commercially available, for example, the Datamyte 900 (Electro/General Corp., Minnetonka, Minnesota)[1], the SSR System 7 (Semeiotic Systems Corp., Madison, Wisconsin)[2], the OS-3 (Gagetalker Corp., Bellevue, Washington) and The Assistant (Human Technologies, Inc., St Petersburg, Florida)[3].

Although these recorders are well adapted to the task for which they were designed, each has its limitations. All of them are dedicated systems. Further, commercially available models are expensive, while others have to be assembled from electronic circuits and, therefore, require technical expertise and considerable input of labour. The maintenance of such equipment also requires specialized personnel.

Use of microcomputers

Commercially available microcomputers that allow data to be entered directly into the computer render custom-designed keyboards largely unnecessary. Moreover, one can rely on dealer networks for maintenance. Perhaps most important of all, is the great flexibility offered by microcomputers — they can be programmed more easily, in high-level languages such as BASIC, Pascal and C. Most are equipped with a printer port, allowing a hard copy of collected data directly after an observation session, and a reasonably sized screen, allowing direct visual feedback during operation. Interaction via the screen also helps alleviate the concern about the 'invisibility' of computer-collected data. Most of these options are not available with dedicated event recorders.

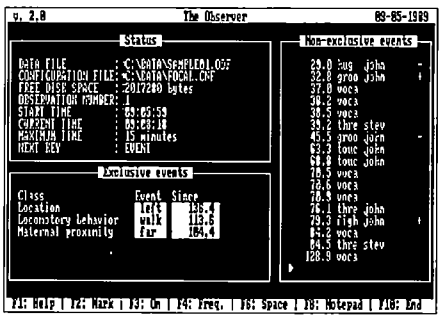

FIG 1 Screen of a personal computer during an observational data collection session.

Today's researcher can choose from a range of different computers for behavioural observations. In fact, any computer that is equipped with a real-time clock can be used as an event recorder. With the aid of alternative input devices — contact sensors and infrared detectors — connected to a communication port or an add-in board, a computer can be used as an activity monitor. In observational research, the type of computer selected depends on various aspects of the study, such as experimental design and location of observations. For instance, complex observations in a laboratory environment may benefit most from a powerful desktop PC, while field studies require a small portable device. As far as permanent data storage and analysis are concerned, today's PCs are powerful enough to perform most of the tasks that required a minicomputer less than a decade ago. Thus, in some circumstances the same device can be used for event recording and data analysis. However, where no direct hardware-compatibility exists between the apparatus on which data are collected and that on which they are to be analysed, a data transfer medium is also necessary.

With computers becoming more powerful, more compact and relatively less expensive, computer event recorders can be applied in an increasing number of different research settings. There are, however, minimum size requirements for direct data entry via a keyboard. For instance, the Psion Organiser II (Psion PLC, London) can store 320 Kbyte and yet weighs only 250 g, but its keys are so small that it does not appear very practical for use as an event recorder.

The accuracy of computerized event recording through manual data entry ultimately depends on the human observer. Most systems time events through the computer clock, which implies that user errors with regard to timing cannot be fixed exactly. If precise timing is at a premium, one solution is to make a video recording and store the real time on the audio track of the video tape. With a specific hardware interface and appropriate software the complete behavioural record can then be edited afterwards at the level of single video frames with the original times still available. Such systems also allow subsequent passes through a video recording for coding of multiple events to a common time base[4] (Mr. R. Kruk, personal communication).

Event-recording software

As computers replace each other in rapid succession, the availability of software becomes the limiting factor in the widespread use of computer event recorders. An event-recording program should be adapted to the machine on which it has to be run, as well as to the experimental design for which it will be used. The flexibility of microcomputers and high-level programming languages facilitates programs with, for example, trapping and correction of user input errors, distinction between frequency versus duration events, mutually exclusive versus non-exclusive events, and storage of independent variables. However, the use of compact portable computers with limited memory and processing speed restricts the size and level of sophistication of event-recording programs.

Event-recording software has been developed for several commercial microcomputers. Some of these programs have been designed for data collection and analysis on a desktop computer, such as the Apple II[5], Macintosh[6] or IBM PC[7]. Most programs operate on a specific combination of a small portable computer for

data collection and a larger computer for analysis, for example, the TRS-80 Model 100/TRS-80 Model 4[8] or Epson PX-8/BBC Model B[9]. Other systems use the IBM PC as a host computer with, for example, a NEC PC-8201A, PC-8300[10], or Epson HX-20[11] as an event recorder. Data-collection software has even been developed for HP41 and HP71 pocketcomputers[12]. However, with the current short lifetime of computer models, specific programs written for a particular type of computer run the risk of soon becoming obsolete.

As most behavioural scientists lack programming expertise, there is a need for general-purpose event recording and data analysis software. Such software should (1) be very flexible with regard to hardware and experimental design, (2) be intuitively understandable and require no programming by the user, (3) be robust against user errors, and (4) produce data in a format compatible with commercially available analysis software.

The Observer (Fig. 1), a recently developed software package for observational research[13], represents an attempt in this direction. This program runs on any IBM-type PC. The user can configure the event recorder accurately to many different experimental designs. With the information entered by the user, the PC can be used directly as an event recorder. In addition, four types of non-IBM compatible portable computers are supported as event recorders: TRS-80 Model 100, Tandy 102, Olivetti M10, and Epson PX-8. For these computers, The Observer generates event-recording programs specifically adapted to the machine and experimental design chosen by the user. As the programs contain only code essential to the current task, they remain compact and occupy a minimum amount of memory in the portable computer. The program transfers generated programs to the portable event recorder and retrieves collected data files. The Observer also analyses observational data and provides the user with statistics in printed reports.

The trend in software is towards computer-user interaction at an increasingly higher level. Ideally, the user should merely have to specify what the problem is, not how it should be solved. The development of such high-level software opens new possibilities for computer-aided behavioural research. With the arrival of computer programs that do the programming, the behavioural scientist can concentrate better on the actual research. □

Lucas P. J. J. Noldus is at the Dept of Entomology, Agricultural Univ. Wageningen, The Netherlands. Erik L. H. M. van de Loo is at the Dept. of Clinical and Health Psychology, Univ. of Leiden, and the Inst. for Human Resource Management, The Netherlands. Paul H. A. Timmers is at Philips Data Systems BV, Apeldoorn, The Netherlands. For more information, fill in the reader service number 100.

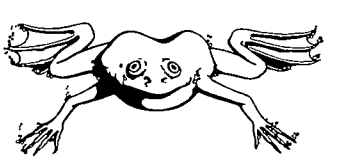
New tools for neuroscience

Exhibits at next week's American Society for Neuroscience Annual Meeting in Phoenix, Arizona include eicosanoid EIA kits and an activity monitor.

THREE new **eicosanoid enzyme immunoassay kits** for the measurement of prostaglandin E_2, thromboxane B_2 and 6-keto-prostaglandin $F_{1\alpha}$ are available from Advanced Magnetics, Inc. (*Reader Service No. 101*). These solution-phase assays are based on the competition of variable amounts of analyte with a fixed amount of alkaline phosphatase-labelled analyte for a limited number of rabbit antibody binding sites. The addition of magnetic goat anti-rabbit antibody, followed by magnetic separation or centrifugation, separates antibody-bound from unbound analyte. The resulting pellet is reacted with para-nitrophenyl phosphate substrate and the absorbance read at 405 nm: sample concentration is determined from a standard curve. AMI says, the prostaglandin E_2, thromboxane B_2 and 6-keto-prostaglandin $F_{1\alpha}$ can detect 0.13 pg, 4.0 pg and 0.12 pg per 0.1 ml sample, respectively. The $295 (US) kits contain enough reagents for 100 assay tubes, including standard curves, says AMI, who will be in booth 425.



Data acquisition

HVS Image will be exhibiting, in booth 2011, their VP118 Super Track Unit **activity monitor** for monitoring the behavioural activity of animals, particularly rodents (*Reader Service No. 102*). The VP118 receives input from a video camera positioned over an open field, water or radial maze. Positional information from the image is extracted by the VP118 and relayed to the user's IBM PC/XT/AT. Super-Track software analyses data for path length, positional preference, and percentage time spent moving. The system can track two animals together, which is useful for studying social interaction, and can also measure rotational activity. In quad mode, the VP118 can track up to four trials at once.

World Precision Instruments, Inc., exhibiting in booths 923-927, will be showing off the PolyGraf/8 data aquisition system, which provides real-time 'gapless' multichannel **data collection, display and storage** in the form of a data logger or scrolling strip chart recorder (*Reader Service No. 103*). The $1,695 (US) PolyGraf/8 system includes a plug-in data acquisition card for a MacII, IIx or IIcx, providing eight channels of single-sided bipolar input, a BNC signal manifold, user-friendly software, and cable assembly. Special features include storage of data files and data display during aquisition and in playback mode, adjustable forward and reverse scrolling speed for visual tracking in playback mode, and multiple channel overlay. With PolyGraf/8, the user can 'mark' data points and take snapshots of points of interest for incorporation into word processing documents. □

APPLICATIONS LABORATORY MANAGER

VG MassLab is a world leader in the manufacture and sale of Organic Quadrupole Mass Spectrometers.

Career progression has created an exciting opportunity at a senior level for a practical self-starter.

The successful candidate will be qualified to at least first degree level, preferably with a PhD, and will be experienced in a wide variety of mass spectrometric techniques.

Proven leadership qualities and the ability to communicate in a commercial environment are essential. VG Instruments plc offers a rapid and stimulating career path with ample scope for original contributions to international symposia.

The position offers a negotiable salary together with the usual benefits package.

Applicants should write with full CV to:

VG MASSLAB
automated mass spectrometry
A VG INSTRUMENTS GROUP COMPANY

Bill McKnight,
VG MassLab Ltd.,
Tudor Road,
Altrincham,
WA14 5RZ,
UK.

(1941)A

MEDICAL RESEARCH COUNCIL
NATIONAL INSTITUTE FOR MEDICAL RESEARCH

POSTDOCTORAL SCIENTIST

Applications are invited for a short-term (three-year) postdoctoral appointment in the Laboratory for Leprosy and Mycobacterial Research which is within the Infections and Immunity Group.

The project will involve studying the recognition of bacterial antigens by the immune system and the mechanisms involved in protective immunity against intracellular parasites. The successful candidate will be expected to interact with molecular biologists, protein chemists and bacteriologists within the Laboratory. Further information about the nature of the work can be obtained from Dr M J Colston on 01-959 3666 extension 2354. The salary will be in the range £12,381 to £20,469 (starting salary dependent on experience) plus £1,650 per annum London Allowance. MRC Pension Scheme option.

Applications including a curriculum vitae, list of publications and the names and addresses of two professional referees should be sent to **Mr C R Russell, Administrative Manager, National Institute for Medical Research, The Ridgeway, Mill Hill, London, NW7 1AA**, not later than 17th November 1989 quoting reference number ILR/0716.

The MRC is an Equal Opportunities Employer. (1938)A

University of Tromsø

PROFESSOR OF BIOCHEMISTRY

AT THE WORLD'S NORTHERNMOST UNIVERSITY.

The position of professor of biochemistry is open at the Institute of Medical Biology (IMB), the University of Tromsø. IMB has research groups in Biochemistry, Cell biology, Medical physiology, Arctic biology, Pharmacology, Experimental pathlogy and anatomy, Normal and Pathological Anatomy, Immunology, Microbiology, Virology, Biotechnology and Clinical chemistry.
There are good opportunities for cooperation between research groups as well as with the University Hospital.
The institute has modern laboratory equipment. There are joint service functions for the Institute, including: glass wash, media preparation, cell culture, electronic, mechanic and carpenter, workshop etc., animal facilities, central storeroom, audio-visual department and electron microscopy.
It is desirable to increase the competence in the areas of protein chemistry, protein engineering and enzymology. National research councils will give considerable support to the advancement of these areas of research in Tromsø. Research and teaching background relevant to our current programmes will be taken into consideration in our evaluation of the applicants. Emphasis will also be given to the ability to collaborate and motivate others for scientific activity.
If the following scenario appeals to you, Tromsø could be the best choice you ever made: clean air and water, unspoiled nature, splendid scenery, exiting wild life and exellent possibilities for outdoor life summer and winter. Tromsø, with its population of 50000, offers you a good selection of restaurants as well as musical and theatrical events. The University of Tromsø has 3500 students and a scientific staff of 350. (W6640)A

The gross salary is at present NOK 276.792 per year. Applications including a complete c.v. and list of publications, should be sent in 5 copies together with the relevant certificates to:
The University of Tromsø, The University Director, Breivika, 9000 TROMSØ, NORWAY
Closing date for applications: 15. November 1989
Full directives for application and further information about the professorship can be obtained at the University at the abovementioned address, or from Dr. Bjarne Østerud, Institute of Medical Biology, University of Tromsø, P.O.Box 977, N-9001 Tromsø, NORWAY. Tel.47 83-44733

University of California, Los Angeles

CLINICAL IMMUNOLOGISTS

Immediate opening available for 2 Clinical Immunologists with experience in HLA typing preferred and research interests in HLA serology and genetics M.D. or Ph.D. required Projects will include supervision of HLA typing, research in HLA typing applications to clinical transplantation Salary range: $37,000 – $47,100 per year commensurate with experience

Send CV, statement of research interests and names of 3 references to **Paul I. Terasaki, Ph.D., UCLA Tissue Typing Laboratory, 950 Veteran Ave., Los Angeles, CA 90024**

UCLA is an Equal Opportunity/Affirmative Action Employer.

Senior Scientists in Biomedical Science — Kanagawa, Japan

We invite applications and/or nominations for the positions of senior scientists of the Institute for Biomedical Science. The Institute, now being reorganized, will consist of four divisions: and we call candidates for the following three divisions:

1. Division of Molecular and Cell Biology
2. Division of Bioengineering and Biomedical Materials
3. Division of Artificial Organs and Organ Transplantation

The Institute is one of the three Centers constituting the parent center, Terumo R & D (Director General: Tetsuzo Akutsu, M.D., Ph D. and 500 researchers). The new R&D building (44,146 sq. meter) is under construction and will be open in December, 1989. It is located in the town of Nakai, Kanagawa Prefecture, one-hour drive away from Tokyo. The town is situated on one of the best geographical environments to live in Japan with an excellent view of Mt. Fuji in the west and Sagami Bay in the south.

TERUMO CORPORATION is a leading manufacturer with an extensive product lineup including artificial organs, pharmaceuticals, transfusion and infusion products, medical electronics, labo products and medical disposables. Terumo has manufacturing R&D and distribution facilities in Japan, U.S.A., Belgium and Australia.

QUALIFICATIONS include a Ph.D., and at least seven-year experience in one of the three above-described specialized areas, and an excellent record of scientific achievement. Successful candidates will have a chance to be promoted to the Division Chief, who is expected to have supervisory responsibilities directing junior staff.

SALARY will be commensurate with experience and qualifications. We offer house accommodation, and benefits package together with the opportunity to work in our newly constructed superb facilities equipped with modern technologies.

A letter of application, C V., list of publications, three professional referees, and your portrait should be sent by the end of November, 1989 to the following address:

Yutaka Tomita, Managing Director,
Technical R & D Division,
Terumo Corporation,
44-1, 2-chome, Hatagaya,
Shibuya-ku, Tokyo 151, Japan.
Phone: 03(374)8020, Fax: 03(374)7493.

Applications will be reviewed continuously until suitable candidates are hired. Promising candidates will be contacted for further discussions on the terms of employment contract.

(W6595)A

TERUMO CORPORATION

THE UNIVERSITY OF NOTTINGHAM
INSTITUTE OF ENGINEERING SURVEYING & SPACE GEODESY

RESEARCH APPOINTMENTS

Applications are invited from suitably qualified persons for several post-doctoral and post-graduate research assistantships, and one SERC-CASE research studentship. These posts are connected with a number of recent research council awards and industrial contracts to the University of Nottingham They cover a wide range of topics, all connected with the Global Positioning System (GPS), and its engineering and geophysical applications

Ideally candidates for the post-doctoral appointments will have a PhD in geodesy, geophysics or surveying, but exceptionally persons with a PhD in other physical sciences will also be considered Salaries will be on the appropriate university salary scales, depending on age and qualifications. The posts will involve a certain amount of travel for fieldwork and to visit other research establishments in the United Kingdom and overseas.

Further details may be obtained from: **Professor V Ashkenazi, Institute of Engineering Surveying and Geodesy, University of Nottingham, Nottingham NG7 2RD. Tel: 0602 484848, ext 2672.** (1933)A

The AFRC Institute of Horticultural Research
Temporary Higher Scientific Officers
(3 year appointments)

Plant Geneticist — East Malling

A vacancy exists, funded under the AFRC Plant Molecular Biology Programme, for a Plant Geneticist/Plant Pathologist with experience in gene identification and mapping. The person appointed will work with Dr Ian Crute to identify genes for resistance to fungal pathogens of Arabidopsis thalliana and to locate such genes on existing linkage maps of the species. The work will involve the development of appropriate inoculation and pathogen-handling techniques, investigation of variation for response to fungal inoculation, inheritance studies and linkage analysis with particular emphasis on RFLP's. Expertise in RFLP identification and analysis desirable. Ref: 91/EM

Molecular Biology — Littlehampton

A Higher Scientific Officer is required to join a small team developing the molecular biology of the edible basidiomycetes, in particular the cultivated mushroom Agaricus bisporus. The principal objective is to develop a transformation system for Agaricus bisporus which will permit the introduction and manipulation of genes of agronomic value both from within the species and from other species and genera. Experience in the techniques of molecular biology will be an advantage. Ref: 43/L

Qualifications: First or Upper Second Class honours degree in biological sciences including a substantial component of plant pathology and genetics, with at least 2 years' relevant post-qualifying experience.

Salary: In range of £10,678-£14,909.

Further details and appliction form quoting relevant reference number from **The Personnel Officer, Institute of Horticultural Research, Bradbourne House, East Malling, Maidstone, Kent ME19 6BJ.** Closing date: 16th November 1989.

The AFRC is an equal opportunities employer. (1919)A

Applications are invited for two tenure track positions available for September 1990. The positions are at the assistant professor level. We are particularly interested in candidates who specialise in

"a synthetic and experimental approach to the study of vertebrate reproductive biology"

"molecular biology of the nervous system and behaviour, with strong developmental and/or genetic components"

Please submit curriculum vitae (including biographic data), short statement of research objectives, names of at least 5 referees, and selected reprints to **The Chairman, Department of Zoology, University of Texas, Austin, TX 78712-1064, USA, before January 1, 1990.**

THE UNIVERSITY OF TEXAS AT AUSTIN IS AN EQUAL OPPORTUNITY/AFFIRMATIVE ACTION EMPLOYER. (NW4402)A

UNIVERSITY OF LONDON
Department of Biochemistry St Bartholomew's Hospital Medical College and University College London
RESEARCH ASSISTANT IN MOLECULAR BIOLOGY

Applications are invited for a postdoctoral or postgraduate research assistant to work on a CRC-funded project in the laboratories of Dr I R Phillip and Dr E A Shephard. The successful applicant will join a group working on the regulation of expression of members of the cytochrome P-450 gene superfamily and the function of their protein products (many of which are of central importance in the metabolism of drugs and carcinogens) Experience in some aspect of molecular biology would be an advantage Salary in the range of 1A or 1B, according to age and qualifications. The post is available immediately. Applications with CV and the names of two referees to **Dr E A Shephard, Department of Biochemistry, University College London, Gower Street, London WC1E 6BT.** As soon as possible. (1931)A

Senior Biochemist

We have just created a post for an ambitious, innovative biochemist, preferably with relevant experience in the drug industry, to establish and lead an important new team in the Biochemistry Department of our Cellular and Molecular Sciences Division.

You will initiate and develop programmes to find immunomodifying drugs for use in auto-immune disease, allergy and asthma. Although a knowledge of immunology would be useful, your primary practical experience will have been in protein characterisation and enzymology.

This is an ideal career opportunity with scope for managerial advancement for an ambitious individual with the right profile of experience and the ability to focus on drug targets.

Glaxo Group Research operates a performance related pay system which will reward your achievement and success in this post. Salary (starting range £19,500 to £23,000) is inclusive of profit related bonus, and is complemented by subsidised sports, social and cafeteria facilities, a non-contributory pension and generous relocation assistance where appropriate.

To apply send a full CV and covering letter which emphasises your major scientific achievements to date to Ted Smith, Research Personnel Manager, Glaxo Group Research, Greenford Road, Greenford, Middlesex UB6 OHE. Telephone: 01-422 3434, ext. 2934, fax number: 01-422 4205. Previous applicants will be automatically reconsidered.

Glaxo Group Research

FEDERAL VACCINE – INSTITUTE, BASEL
EIDG. VAKZINE – INSTITUT, BASEL

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the above post available immediately or on an agreed date. The project, funded by the Swiss National Science Foundation, involves studies on the

molecular basis of the biological variability of classical swine fever virus

Experience in molecular biology is required.

The initial appointment will be for one or two years. Salary is according to the Swiss National Science Foundation (starting with SFr. 57.000 per annum).

Please send CV, bibliography, a brief statement of research experience, plus names and addresses of two references to:

Eidg. Vakzine-Institut
Postfach CH-4025 BASEL

Informal enquiries about the post may be made by telephone to Dr. M. Ackermann (0041-61-322 8220). (W6591)A

ASSISTANT/ASSOCIATE PROFESSOR

The Department of Microbiology and Molecular Genetics at the University of Medicine and Dentistry of New Jersey-New Jersey Medical School is seeking several outstanding scientists (Ph.D. or M.D.) for tenure-track, assistant or associate professor positions to be filled in 1990-1991. Successful candidates will be expected to establish a strong basic research program that is molecular in its approach and to participate in Medical and Graduate School teaching. The Department has excellent facilities and is part of a large medical complex. We are particularly intersted in candidates studying either the molecular bases of microbial pathogenesis, retroviruses (especially HIV) or other viral systems. However, we encourage all qualified individuals with interest in molecular biology to apply.

Send a curriculum vitae, a statement of research interests and names and addresses of three references to: **Dr. Lynn S. Ripley, Faculty Search Committee, Department of Microbiology and Molecular Genetics (N), UMDNJ-New Jersey Medical School, 185 S. Orange Avenue, Newark, NJ 07103.**

UMDNJ is an Equal Opportunity/Affirmative Action Employer (NW4442)A

BIOLOGICAL OCEANOGRAPHER

The Department of Organismic and Evolutionary Biology and the Committee on Oceanography at Harvard University seek to make an appointment in biological oceanography at the rank of assistant professor Preference will be given to candidates with interests in phytoplankton processes In addition to research interests in oceanography, the applicants should be prepared to teach oceanography at the undergraduate and graduate levels, and in the area of phycology at the introductory level. Applicants should send a curriculum vitae, statement of research interests, and the names of three references to **James J. McCarthy, Chairman, Search Committee for Biological Oceanography, MCZ, Harvard University, Cambridge, MA 02138**

Harvard University is an Affirmative Action/Equal Opportunity Employer (NW4452)A

Post Doctoral Position

Two positions are available to study the mechanism and regulation of protein secretion in gram positive bacteria. Experience in molecular biology and/or biochemistry in a related field is desirable

The position is initially for up to 3 years with possible prolongation Salary is according to BAT

Send curriculum vitae, list of publications and the names or letters of 2 references to

Dr. Roland Freudl
Institut fur Biotechnologie 1;
Kernforschungsanlage Jülich GmbH
Postfach 1913
5170 Julich
Federal Republic of Germany. (W6449)A

UNIVERSITY COLLEGE LONDON
Department of Biology
WO APPOINTMENTS IN PLANT PATHOLOGY/MYCOLOGY

1 A post-doctoral research assistant is required immediately to study the morphological and biochemical basis of the resistance of wheat to the fungal pathogen *Fusarium graminearum*. Work on the project will be in collaboration with an Agricultural Station in Uruguay and CIMMYT, Mexico. Candidates should have good practical experience of general biochemical techniques.

The appointment, which is funded by the Overseas Development Administation, is for three years and will be on the RA 1A scale. The initial salary will be determined by age and experience and will be up to a maximum of £14,169 + £1,650 London Allowance.

2. A post-graduate, who may register for the Ph.D. degree, is required to investigate the occurrence of moulds and mycotoxins in oilseed rape at harvest, during storage and following conversion into cake Work on the project will be in collaboration with the Overseas Development and Natural Resources Institute and laboratories in Italy and Pakistan Candidates should have some knowledge of the culture and identification of fungi and the quantitative analysis of biologically active compounds.

The appointment, which is for three years, is funded by the EEC The successful candidate will be renumerated at the standard SERC studentship rate (currently £4690 + travel allowance).

Further particulars may be obtained from **Dr. R. N. Strange, Department of Biology, Darwin Building, University College London, Gower Street, London WC1E 6BT** to whom applications, including cv and the names and addresses of two referees should be sent. (1921)A

University of Mainz
Institute of Toxicology
Research Associate
Biochemist

We are a multidisciplinary team working on control factors in chemical carcinogenesis and are inviting applications of biochemists to work on the above topic particularly including the purification and biochemical and toxicological characterization of soluble and membrane-bound foreign compound metabolizing enzymes.

Evidence of ability to establish and conduct an innovative and vigorous research program in biochemical toxicology or related fields is expected.

We are interested in individuals with profound experience in enzymology and protein (bio)chemistry and basic experience in molecular biology. Modest participation in teaching courses of Pharmacology and Toxicology will be part of the duties. Basic knowledge of German is required.

Salary is equivalent to BAT IIa depending on age and family status. The position is available for three years (then extendable) starting 1 December, 1989. Habilitation is encouraged.

Send a resume including research experience and letters of reference to **Prof. Oesch, Institute of Toxicology, University of Mainz,** Obere Zahlbacher Straße 67, D-6500 Mainz, FRG. (W6641)A

IMMUNOLOGISTS

The University of Washington seeks highly-qualified applicants for tenure-track appointments in the newly formed Department of Immunology. Applicants must have demonstrated their ability to establish strong independent research programs in immunobiology. The Department of Immunology offers superb new laboratory space with access to flow cytometry, biopolymer synthesis, and transgenic animal facilities. Send curriculum vitae, a brief description of proposed research, and three letters of recommendation (by December 1, 1989) to **R.M. Perlmutter, M.D. Ph.D., Chairman, Department of Immunology, SL-05, University of Washington, Seattle, WA 98195.**

The University of Washington is an Equal Employment/ Affirmative Action Employer. (NW4287)A

WOLFSON RESEARCH PROFESSORSHIP

The Wolfson Research Professorship, held by Professor Dorothy M.C. Hodgkin, O.M., from 1960 to 1977 and by Professor A.R. Fersht from 1978 to 1989, is now vacant and applications are invited by the Council of the Royal Society for appointment from 1 October 1990 or thereafter. The professorship will be for research in physics or chemistry at their interfaces with biology.

The appointment will be subject to the Society's General Regulations governing Royal Society Research Professorships. Candidates must be British citizens or citizens of independent Commonwealth countries and must hold the appointment in a university or other research institution in the United Kingdom.

Salary and conditions of tenure

The salary will be on the prevailing professorial minimum for professors in United Kingdom universities plus one-third (making a current total of £33 044 p.a. with London Allowance £1650 p.a. where appropriate) and tenure is for five years in the first instance, renewable thereafter until age 65. Superannuation benefits will be provided and there is provision for research expenses (currently £13 500 p.a.), support of a research assistant or technician and start-up expenses (up to £35 000).

Method of application

Intending applicants should write for further details, which will be issued up to 4 December 1989, (there is no application form) to:

Mrs U.M.A. Tokle, The Royal Society,
6 Carlton House Terrace, London, SW1Y 5AG.

Closing date: 15 December 1989. No applications arriving after 4 p.m. on 15 December will be considered. (1840)A

Post Doctoral Molecular Biologist
at AFRC, Institute of Animal Physiology & Genetics Research Babraham, Cambridge

Post doctoral research fellow required for a productive, multi-disciplinary group studying interferon gene expression in the early embryo in cattle and sheep using bovine genomic promoter sequences Techniques to be applied include construction of hybrid reporter gene, transfection and culture of eukaryotic cells and assay of transcription Experience in this field would be an advantage but training could be given The position, available for two years, supported as part of the University of Nottingham AFRC Research Group on Hormones and Farm animal Reproduction, would suit a young post doctoral biochemist wishing to contribute to an exciting and expanding project with important commercial implications which arise from the central role of trophoblast interferons in early pregnancy in domestic species. Salary £12,381-£16,665 pa Further details from Professor A P F Flint (tel: 01 722 3333) or Dr H J Stewart (tel: 0223 832312)

Applications with the names of three academic referees to **Professor G E Lamming, Department of Physiology & Environmental Science, University of Nottingham, Sutton Bonington, LOUGHBOROUGH, LE12 5RD** *Closing date* 23 November 1989. (1917)A

BAKER MEDICAL RESEARCH INSTITUTE
MOLECULAR BIOLOGIST/ BIOCHEMIST

Applications are invited from Molecular Biologists/Biochemists for the position of Staff Scientist or Post Doctoral Research Fellow at Australia's largest cardiovascular research institute The successful applicant will join the biochemical pharmacology laboratory and participate in studies on paracrine and autocrine mechanisms affecting vascular smooth muscle growth and on vascular hypertrophy in hypertension. Appointment at the staff scientist level will initially be for 12 months and after this qualifying period can be made permanent. Staff scientist salary· @A31,039-@A36,384 p a. Appointment at the post doctoral research fellow level @A28,500-@A30,500 p.a.

Applications including curriculum vitae and two letters of reference sent to· **Ms S.A. James, Baker Medical Research Institute, P.O. Box 348, Prahran, Victoria, Australia.** (1959)A

UNIVERSITY OF OTAGO
Dunedin, New Zealand

CHAIR OF PHARMACEUTICAL CIENCES IN THE DIVISION OF HEALTH SCIENCES

pplications are invited for ppointment to the Chair of harmaceutical Sciences in the niversity of Otago which ecomes vacant with the resigna-on of Professor M S Roberts. his is one of two Professorial ppointments within the Depart-ent of Pharmacy; the other being eld by Professor P F Colville who also Administrative Head. Prof-sorial salaries are fixed at arious points within the present nge NZ$76,000 per annum to Z$95,000.

Further particulars are available om Appointments (37066), ssociation of Commonwealth niversities, 36 Gordon Square, ondon WC1H 0PF; or from the egistrar, University of Otago, . Box 56, Dunedin, New land.

Applications quoting reference umber A89/48 close on *31 ecember 1989.*

Equal opportunity in employ-ent is University policy.

(W6637)A

INTERDISCIPLINARY RESEARCH GROUP IN FETAL AND NEONATAL HEALTH AND DEVELOPMENT UNIVERSITY OF WESTERN ONTARIO LONDON, ONTARIO, CANADA

The Medical Research Council of Canada has recently established an Interdisciplinary Research Group to study the biology of **Fetal and Neonatal Health and Development.** The research interests of the group range from basic molecular biology/biochemistry and physiology to biophysical monitoring of fetal health. The group is serviced by a number of specialized facilities including a large animal service unit and a molecular biology core/training laboratory. Research training opportunities are now available at the **Postdoctoral** and **Graduate Student** levels in the laboratories of one or more of the following participating faculty:

John Challis
Fetal-maternal endocrinology, control of parturition

Alan Booking
Uterine blood flow and fetal growth and development

Geoffrey Hammond
Steroid hormone action and control of mammalian gene expression

Victor Han
Insulin-like growth factor gene expression and function in development

David Hill
Hormonal control of tissue growth and differentiation

David Olson
Eicosanoid (prostaglandins, leukotrienes) synthesis, regulation and biological actions in relation to parturition and pulmonary physiology

John Patrick
Assessment of Fetal Health

Fred Possmayer
Structure and function relationships of pulmonary surfactant associated proteins. Control of lipid metabolism

Bryan Richardson
Fetal cerebral metabolism. Biological and pathological development

Interested candidates should send a resume indicating any preference for particular areas of research to: **Dr. J.R.G. Challis, Director, MRC Group in Fetal & Neonatal Health and Development, Lawson Research Institute, 268 Grosvenor Street, London, Ontario, N6A 4V2.** (NW4441)A

POSTDOCTORAL FELLOW NEUROSCIENCE

Available Jan, 1990 or later in laboratory studying mechanisms of synaptic plasticity and transmitter action in mammalian CNS. Standard Electrophysiological techniques including patch clamp are utilized. Collaboration with neurochemists/molecular biologist possible.

Send C.V. and names of 3 references to:

Dr. Robert Malenka,
Dept. of Psychiatry & Physiology,
LPPI, Box F-0984, University of California,
San Francisco, CA. 94143.

(UCSF is an affirmative action/equal opportunity employer. Women and minorities are encouraged to apply.) (NW4437)A

MOLECULAR BIOLOGIST-MICROBIOLOGIST

Twelve-month tenure-track faculty position. Should be interested in studying bacterial disease pathogenesis, microbial virulence factors or host defenses mechanisms. Seek scientist to apply modern molecular biology techniques to the study of bacterial diseases involving respiratory, enteric or reproductive systems of food producing animals. Will be expected to develop a competitive research program and participate in training graduate students.

Start-up funds, technical support and excellent laboratory and animal isolation facilities (BL2 and BL3) are available. Requires DVM (or equivalent) and Ph.D or Ph.D in an appropriate discipline. Rank and salary will be commensurate with record of accomplishments.

Send curriculum vitae and statement of research/career interests by January 3 to: **Dr. John A. Schmitz, Head, Department of Veterinary Science, University of Nebraska-Lincoln, Lincoln, Nebraska 68583-0905. (402) 472-2952.**

Affirmative Action/Equal Opportunity Employer. (NW4436)A

FACULTY POSITIONS IN PHARMACOLOGY

The Department of Pharmacology at the University of Texas Southwestern Medical Center at Dallas seeks applicants for tenure-track positions at the level assistant or associate professor. Applicants must have a relevant Ph.D. or . degree and postdoctoral training and must show evidence of a firm commitment to a career in independent research. We are particularly interested in applicants who plan to apply techniques of cellular or molecular biology or biochemistry to fundamental problems of pharmacological interest. Responsibilities include teaching graduate and/or medical students after the first year of employment. Send curriculum vitae, list of 3 referees and a brief description of proposed research to **Alfred G. Gilman, Chairman, Department of Pharmacology, University of Texas Southwestern Medical Center at Dallas, 5323 Harry Hines Boulevard, Dallas, Texas, 75235-9041.** *An Equal Opportunity/Affirmative Action Employer* (NW4289)A

MEDICAL RESEARCH COUNCIL
MAMMALIAN DEVELOPMENT UNIT

Applications are invited for the position of NON-CLINICAL SHORT-TERM SCIENTIST, interested in gene expression or some aspect of post-implantation development in mice. Candidates should hold a PhD or equivalent.

Remuneration will be at an appropriate point on the MRC non-clinical scientific scale. Further information may be obtained from Dr Anne McLaren, MRC Mammalian Development Unit, Wolfson House (UCL), 4 Stephenson Way, London NW1 2HE, Tel: 01-387 9521 with whom applications — including a full CV, detailed research proposals and the names of two professional referees — should be lodged by November 16th 1989. Medical Research Council

APPLIED BIOCHEMIST

VG MassLab manufacture quadrupole mass spectrometers for applications in areas such as toxicology, environmental monitoring and biochemistry.

An exciting new technique for the analysis of large bio-polymers, especially proteins, has recently been introduced. As a result a vacancy has arisen for an applied biochemist to carry out research and development into the applications of this new method.

Experience of preparative methods such as LC separations and enzymatic digests would be an advantage, as would a knowledge of mass spectrometry.

As an employee of VG Instruments plc, one of the world's major scientific instrumentation companies, the successful applicant can look forward to a rewarding career with opportunities for advancement within this fast-growing, ambitious company. Some overseas travel will be involved.

Salary will be in line with experience and qualifications, and the usual company benefits are offered.

Please apply in writing to:

Brian Green,
VG MassLab Ltd.,
Tudor Road,
Altrincham,
WA14 5RZ,
UK

VG MASSLAB

A VG INSTRUMENTS GROUP COMPANY

(1940)A

UNIVERSITY OF GLASGOW
ROBERTSON INSTITUTE OF BIOTECHNOLOGY
DEPARTMENT OF GENETICS

LECTURESHIP IN BIOTECHNOLOGY

Applications are invited for a University Lectureship in Biotechnology in the Robertson Institute of Biotechnology within the Department of Genetics. The Robertson Institute is being built adjacent to the Institute of Genetics and will share facilities with it. The Intitute was created by a recent generous benefaction and will house the Robertson Professor of Biotechnology (Professor R.W. Davies) and three University biotechnology lecturers (including the successful applicant)

Applicants should have a proven research record in an area that augments the research activities of the biotechnologists and geneticists within the Department. Applications from those with an existing or planned research programme using higher organisms in a Health-Care related field, would be particularly welcome The Department is very active and well equipped for research in molecular genetics using a variety of microbial and animal systems and will shortly have a facility for work with transgenic animals. The major areas of research by the biotechnology staff are. applied molecular neurobiology (Professor R.W Davies); differential gene expression in animal systems (Dr K. Kaiser); and gene expression and secondary metabolism in *Streptomyces* (Dr I.S. Hunter)

Salary will be within the range £10,458 - £20,469 on the Lecturers' scale with placement according to age, qualifications and experience Informal enquiries may be made to Professor Davies, Professor Sherratt or Dr Sutcliffe, Department of Genetics (Tel: 041-330 5113).

Further particulars can be obtained from the Academic Personnel Office, University of Glasgow, Glasgow, G12 8QQ, where applications (8 copies), a short research proposal and the names and addresses of three referees, should be lodged on or before 15th November, 1989. In reply please quote Ref No: 6730. (1897)A

(NW3837)A

UNIVERSITY OF LONDON
The Medical College of St Bartholomew's Hospital
West Smithfield, London EC1A 7BE

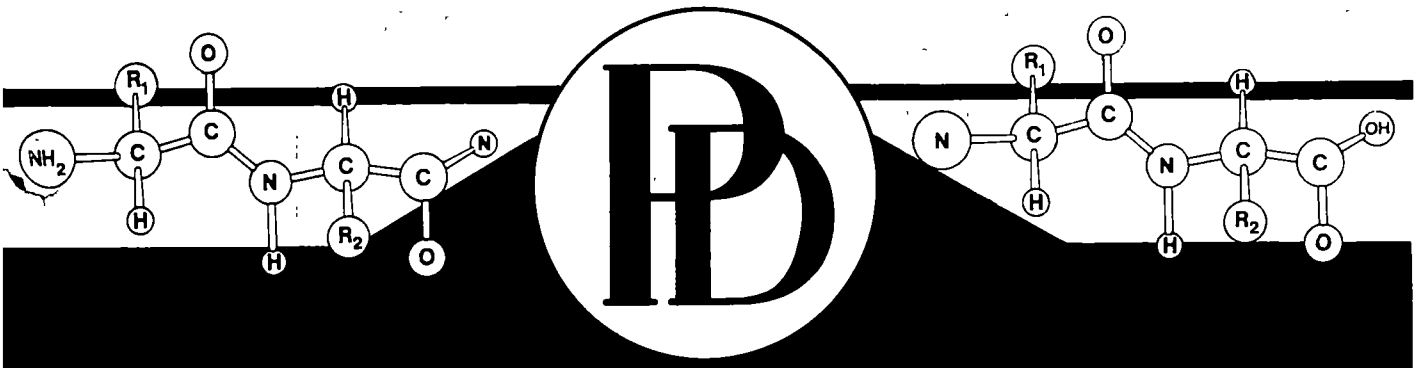
LECTURESHIP IN BIOCHEMISTRY
AT QUEEN MARY AND WESTFIELD COLLEGE (QMW)

Applications are invited for the above position tenable from 1st October, 1990 in a new Department of Biochemistry at QMW formed by the merger of the Departments of Biochemistry of the Medical Colleges of St Bartholomew's Hospital and The London Hospital The Department will be situated in a purpose built and newly equipped building designed to house the Faculty of Basic Medical Sciences of QMW as part of an exciting development in biomedical sciences within the framework of the City and East London Confederation (CELC), comprising QMW and the two Clinical Schools, St Bartholomew's HMC and The London HMC.

Applicants should have a PhD and postdoctoral experience in Biochemistry or any closely related discipline ranging from Molecular Biophysics to Cell Biology. Preference will be given to candidates with a proven track record involving substantial publication and the ability to attract research grant income.

Salary according to age and experience on either Grade A or Grade B Lecturer scale. Copies of the job description can be obtained from the Medical College (tel 01-606 7404) quoting reference JR.123.

Applications in the form of a curriculum vitae (9 copies please) should be sent to the **Dean of St Bartholomew's Hospital Medical College** together with the names of three referees, by *1st December 1989.*



(1910)A

HYDROGEOLOGY
UNIVERSITY OF MARYLAND, COLLEGE PARK

The Department of Geology, University of Maryland, College Park, invites applications for faculty positions in the general area of groundwater or surficial hydrogeology. Candidates with strong modeling backgrounds are particularly encouraged to apply

Higher education in Maryland has recently undergone reorganization, and the College Park campus has been officially designated as the flagship campus of the University of Maryland system The growth and development of Geology at College Park is part of this overall plan. The Department offers B.S , M.S., and Ph D degrees, and research is conducted in a number of areas within the department including glacial geology and geomorphology, tectonics, igneous and metamorphic petrology, nuclear waste isolation, geochemistry, experimental petrology and mineralogy, sedimentation and economic geology. Further there are numerous federal and private laboratories in the Washington, D C area including USGS National Center, NASA, DTM, Geophysical Laborato NIST (NBS) and the Smithsonian Institution

Appointments will begin August, 1990. The Ph.D. is required The rank and salary are open, but our preference is to appoint at a senior level. The successful candidates will be expected to develop strong research and teaching programs. Applicants should send a detailed resume, a statement of research and teaching interests and the names of three references to **Chair, Hydrogeology Search Committee, Department of Geology, University of Maryland, College Park, MD 20742.** For full consideration applications should be received by February 1, 1990. The University of Maryland is an equal opportunity/affirmative action employer. Women and minorities are encouraged to apply. (NW4445)A

Parke Davis Research Unit, Cambridge.

DIRECTOR: DR JOHN HUGHES

RESEARCH ASSOCIATES IN NEUROPHARMACOLOGY/ELECTROPHYSIOLOGY

This unique Unit is developing new generation drugs for the treatment of nervous and neurohormonal disorders. Our basic research interests centre on the function and mechanism of actions of hormones and neurotransmitters at the behavioural, cellular and molecular levels with particular reference to peptides. We have a number of strong research programmes involving permanent staff, Ph.D. students and Post-Doctoral Fellows. Collaborative projects with various University, Research Council and Hospital research groups are also in progress.

The opportunity has arisen for two young, highly motivated neuroscientists or pharmacologists to join a team studying the electrophysiological actions of neuropeptides and centrally-acting drugs using brain slices and cultured neurons. Applicants for these tenured positions should hold, or be expecting to obtain, a good first degree in Pharmacology/Physiology, Neuroscience or a related subject. Full training can be provided for a suitable candidate who may not have extensive experience in electrophysiological and tissue culture techniques but who wishes to develop their expertise in these areas. The successful candidates will be encouraged to contribute to the active publication programme of the research group and to participate at scientific meetings. These positions, which are available immediately, carry a salary on a scale rising to £21,061 per annum. Starting salary will be dependent upon qualifications and experience. Other benefits include relocation assistance where appropriate.

Applications should be accompanied by a full up-to-date curriculum vitae describing research experience, together with the names of two scientific referees and be sent to Dr. Chris Bruton, Parke-Davis Research Unit, Addenbrookes Hospital Site, Hills Road, Cambridge, CB2 2QB, to arrive as soon as possible and in any event by 10th November 1989.

WARNER LAMBERT

(1915)A

ansto

AUSTRALIAN NUCLEAR SCIENCE AND TECHNOLOGY ORGANISATION

DIRECTOR

RESEARCH AND DEVELOPMENT IN ENVIRONMENTAL SCIENCE

The Australian Nuclear Science and Technology Organisation (ANSTO) is Australia's major centre of competence and expertise in nuclear science and associated technologies and is located at Lucas Heights, some 30 km south of Sydney. It has an annual budget of $65 million which is directed to the development and application of nuclear science and technology in industry, medicine, agriculture and other fields.

Opportunities exist for interaction, collaboration and co-operation with outside organisations to facilitate technology transfer.

ANSTO's Strategic Plan outlines the basis for the provision of "Nuclear Technology for the Benefit of the Community and Commerce". ANSTO therefore has two roles

- the principal role is the research and development of strategic nuclear scientific knowledge and the maintenance of Australia's nuclear competence; and
- the commercial application of ANSTO's skills, equipment and facilities to support Australia's industrial and technological development.

A SCIENTIST OF STATURE IS SOUGHT TO HEAD THE ENVIRONMENTAL SCIENCE PROGRAM.

The program area comprises around 65 scientists and support staff and projects span the diverse field of physics, biology, microbiology, chemistry and chemical engineering Major project areas include hydrogeochemical and atmospheric transport; ecotoxicology; radioecology; chemistry of ground, surface and marine waters; water and wastewater treatment processes; hydrometallurgical processing; bioleaching of ores and wastes, waste treatment, management, disposal and rehabilitation A major aim of the program is to transfer the derived technology to industry via consultancies and collaborative research.

The program investigates the processes controlling the release and the water and airborne dispersion of mining and industrial pollutants, and assesses their biological impact on the environment. It assists in minimising the environmental impact of industry through the development of more efficient methods for processing uranium and other ores and for the management and rehabilitation of wastes.

Much of the work of the program has been associated with the nuclear industry and in particular uranium extraction. More recently, however the program has diversified into Research and Development on related but more generic problem areas in support of Australian industry and on natural processes relevant to general environmental degradation.

The Director has responsibility for and is accountable for the management of the Program. The Director is required to provide strong leadership in its research activities and is required to determine the future directions of research within the Strategic Plan.

The person will be of an outstanding scientific standing and have made a major contribution in at least one of the research areas outlined above A good working knowledge of the major issues in the environmental area and demonstrable expertise in linking Research and Development to industrial needs. The position calls for a visible leader who has highly developed analytical abilities, exercises commercial judgement, is able to motivate and manage scientific staff and provide corporate direction.

The salary with other benefits of superannuation, allowances and car provides for a total package in the order of A$75,000. Financial assistance is available for relocation if the successful applicant is from outside of Sydney.

Further enquiries may be made to Mr D. R. Davy, General Manager Scientific, on telephone (02) 543 3702 or Facsimile (02) 543 6907.

Written applications should be forwarded to the Executive Liaison Officer, ANSTO, Private Mail Bag 1, Menai, NSW 2234, Australia.

For permanent appointment applicants must be Australian citizens. Other applicants will be considered pending completion of citizenship requirements

Closing date for applications is 24 November 1989.

ANSTO IS AN EQUAL OPPORTUNITY EMPLOYER (W6444)A

AGRICULTURAL AND FOOD RESEARCH COUNCIL

INSTITUTE FOR ANIMAL HEALTH
COMPTON, NEWBURY, BERKS
RG11 0NN

POST-DOCTORAL MOLECULAR BIOLOGIST

HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER required to work on the prion protein (PrP) gene. Initially he/she will construct recombinant plasmids and viruses in order to obtain *in vitro* expression of PrP. The project will examine the properties of PrP expressed from recombinant viruses and analyse, through *in vitro* mutagenesis, the functional and structural domains of the protein.

PrP is a normal protein which has a key role in the pathogenesis of transmissable encephalopathiesis, such as scrapie and Creutzsfeldt-Jakob disease. Knowledge of PrP structure should define its function in the cell and the molecular lesions in the protein which lead to the expression of degenerative disease.

This is a three year appointment initially with a view to permanency.

Qualifications: A good honours degree in an appropriate subject with at least three years relevant post graduate experience and preferably a PhD.

Salary: Higher Scientific Officer £10,678-£15,504. Senior Scientific Officer £13,254-£19,619.

Non contributory pension. Up to £5,000 assistance with removal expenses.

Application forms from the Personnel Office at the above address.

An Equal Opportunities Employer. (1914)A

Duke University

2 tenure track positions — Geophysicist: Asst. or assoc. prof level; Hydrogeologist: Asst. prof. Send c.v., statement of research interests and names of 4 referees by Dec. 15. **Search Committee, Dept. of Geology, Duke Univ., Durham, NC 27706 USA.** (NW4412)A

MAX-PLANCK-INSTITUTE FOR BRAIN RESEARCH

NEUROBIOLOGIST

The successful candidate will run a small independent research group within the department of neuroanatomy. Candidates with an interest in the biochemistry of the vertebrate retina *in vitro* will be preferred. The position is limited to five years.

Applications to: **Heinz Wassle, Max-Planck-Institute fur Hirnforschung, Deutschordenstr. 46, D-6000 Frankfurt 71, West Germany.** (W6454)A

POST DOCTORAL POSITIONS IN CHEMICAL CARCINOGENESIS

One position for research on molecular mechanisms of tumor induction by N-nitroso compounds. Experience in techniques of molecular biology an advantage, but not essential. Second position for research on isolation and characterisation of agents in food responsible for initiation and/or promotion of colon cancer using new short terms assays. Send CV and names of references to: **Dr. Michael C. Archer or Dr. W. Robert Bruce, Department of Medical Biophysics, University of Toronto, Ontario Cancer Institute, 500 Sherbourne Street, Toronto, Canada M4X 1K9.** (NW4462)A

POST-DOCTORAL POSITIONS IN PHYSIOLOGY OF EYE

Two positions available 1 Jan 1990 to study photoreceptor adaptation (J Physiol **416**, 215–243), ganglion cell synaptic receptors (J Physiol **418**, 53–82) or cell physiology of ciliary epithelium (J Physiol **418**, 83–103). US $23,000 plus health. **Gordon L. Fain, Professor and Associate Director, Jules Stein Eye Institute, UCLA Sch. Med., Los Angeles, CA 90024-1771.** *EOE/AA* (NW4434)A

Postdoctoral Position

available immediately for a recent Ph D. in biochemical pharmacology with interest in cellular nucleoside/nucleotide metabolism and membrane transport. Experience in recombinant DNA techniques an asset. This position is funded by an RO1 grant for up to 3 years (Salary range $18,000-$24,000) Please send CV and a letter describing research interest and salary requirements to. **Dr. Thomas Chan, Lynn Hall, Purdue University, W. Lafayette, IN 47907, U.S.A.** (Purdue University is an equal opportunity employer). (NW4443)A

POSTDOCTORAL POSITIONS IN MOLECULAR DEVELOPMENTAL BIOLOGY

● **Paul F. Goetinck, Ph.D., Program Director,** Role of cell surface components and extracellular matrix in morphogenesis. (Molecular characterization of interactions of membrane associated heparan sulfate proteoglycans and other cell surface components with extra-and intracellular ligands and molecular analysis of the regulation and assembly of macromolecules of the extracullar matrix of cartilage).

● **José Luis Millán, Ph.D.** Tissue-specific expression, regulation and function of human and mouse alkaline phosphatases. (Gene regulation studies to identify DNA sequences responsible for germ-cell and placental-specific expression. Generation of a mouse model for hypophosphatasia using homologous recombination).

● **Barbara Ranscht, Ph.D.** Selective expression, molecular interactions and function of cell surface components in nerve guidance. (*In vitro* mutagenesis and gene transfer into heterologous mammalian cells and vertebrate embryos to study interactions and developmental role of twin novel cell adhesion molecules expressed during nerve fiber growth; mechanisms of tissue-specific expression of these genes by identifying regulatory DNA elements).

● **William B. Stallcup, Ph.D.** Role of cell surface components in the developing nervous system. (Biochemical, molecular, and cell biological techniques to study cell-cell and cell-matrix interactions mediated by molecules such as NILE glycoprotein, NG2 chondroitin sulfate proteoglycan, and D1.1 ganglioside).

The La Jolla Cancer Research Foundation, designated by the National Cancer Institute as a Basic Science Cancer Center, is engaged in research at the interface of cancer biology and developmental biology. The campus is located in the La Jolla scientific community.

Candidates must have a Ph.D. or M.D. and a strong background in developmental, cell and/or molecular biology. Submit curriculum vitae and three references to the individual faculty members or program director.

Ph. D. Research Scientist

UCB - a leading European Industrial Group located in Belgium enjoying international expansion.

UCB - 80 units worldwide : research centers, manufacturing plants, marketing, sales and distribution units specialised in the fields of pharmaceuticals, fine chemicals and chemical specialties, and packaging films.

UCB - turnover of 35 billion BEF in 1988.
The group employs some 7,600 people of whom 2,000 in the pharmaceutical division.
Research expenditure in pharmaceuticals reaches 1,1 billion BEF.

UCB-Pharmaceuticals has got a long term commitment to research & development in the fields of cardio-vascular deseases, disturbances of the Central Nervous System and immunology.

We are looking for a (W6448)A

to be responsible for the electrophysiological studies in animals in the Neuropharmaceutical Department of the R&D division located near Brussels.

The ideal candidate will have some experience of C.N.S. electro-physiology. However, consideration will also be given to candidates possessing related qualifications, who are interested in entering a new field. Opportunities for acquiring the relevant background and training will be provided.

UCB offers competitive remuneration with excellent opportunities for professional recognition and career progression.

Please send your application with detailed C.V. to Mr. J. HAMELS, Recruitment and Selection Manager, UCB-Pharmaceuticals, Chemin de Foriest, B-1420 Braine l'Alleud.

UNIVERSITY OF ULSTER

LECTURESHIP IN MICROBIOLOGY

at Coleraine
Ref: C89/260

To contribute to the teaching of microbiology and related areas, to participate in course development and administration, and to undertake relevant research.

Applicants should hold a first or upper second class degree, and preferably a higher degree, in a relevant discipline and should have had research experience in an applied area, such as the molecular biology, genetics, or biochemistry of medically or industrially relevant micro-organisms

Salary will be determined by age, qualifications and experience within the Lecturer A or Lecturer B scale: £10,458-£15,372 and £16,014-£20,469 per annum respectively.

Further details and application forms may be obtained from the **Staffing Officer, University of Ulster at Coleraine, Cromore Road, Coleraine, Co Londonderry BT52 1SA (telephone. Coleraine (0265) 44141, ext 4348).** Closing date: 17 November 1989. An equal opportunity employer. (1935)A

RESEARCH FACULTY POSITION

The Public Health Research Institute (PHRI) invites applications for appointment as a member of its research faculty at either the junior or senior level. Candidates must have training and experience of the highest quality and an exciting research program addressing fundamental questions in eukaryotic or prokaryotic cell biology, virology, or molecular genetics The research program must be funded or, in the case of a junior applicant eminently fundable.

The PHRI is an independent, not-for-profit research organization founded in 1942. Its current programs center on basic molecular biology and molecular genetics.

The PHRI offers an excellent research environment and laboratory facilities, start-up funds, and a generous benefits package. Salary is negotiable.

Candidates should submit curriculum vitae, a statement of research interests and accomplishments, and a list of at least three references. Review of applications will begin on 11 December 1989, but applications will be accepted until the position has been filled. Applications should be sent to: **Dr. Leonard Mindich, Chairman, Recruitment Committee, Public Health Research Institute, 455 First Avenue, New York 10016.**

The PHRI is an Equal Opportunity Employer

POSTDOCTORAL POSITION

Available from Jan 1990 for two years

to study mesoderm differentiation of Drosophila (see Leiss *et al.*, Development **104**, 525 (1988) and Gasch *et al.*, PNAS **86**, 3215 (1989).

Applicants should be recent PhD's with experience in developmental genetics and/or molecular biology.

Applications, including CV, two letters of recommendation, short description of experience and interest should be sent to:

Dr. Renate Renkawitz-Pohl, Genecenter, Max-Planck-Institute for Biochemistry, D-8033 Martinsried, FRG. (W6451)A

Phd Neuroscientists

Merck Sharp & Dohme Research Laboratories, an international leader in pharmaceutical research, has established the Neuroscience Research Centre in pleasant countryside near Harlow in Essex. The Centre is one of the world's largest laboratories dedicated to neuroscience research and has an active Medicinal Chemistry group engaged in the synthesis of novel molecules designed to interact with specific enzymes and neurotransmitter receptors in the central nervous system.

As part of our continued development, we have vacancies for two senior neuroscientists in the Biochemistry Department The successful candidates should possess a keen interest in the application of biochemical techniques to the discovery and evaluation of novel drugs acting on the central nervous system, and a proven record of innovative research.

Candidates for these positions should be post-doctoral scientists in the neuroscience field. Experience in one or more of the following areas would be an advantage:– receptor autoradiographic techniques, *in situ* hydridisation and immunocytochemistry, study of ion channels in the nervous system, the application of neural cell culture techniques. Previous employment in the pharmaceutical industry would be welcomed.

Write with details of your research experience to: Cathy Woodbine, Personnel Manager, Merck Sharp & Dohme Research Laboratories, Terlings Park, Eastwick Road, Harlow, Essex, CM20 2QR.

BIOMOLECULAR NMR SPECIALIST, FACULTY OPENING IN BIOCHEMISTRY

UNIVERSITY OF ILLINOIS

The Department of Biochemistry at the University of Illinois is seeking applicants for a faculty position to be filled by a researcher specializing in the study of biological macromolecules by high resolution NMR spectroscopy. The position, which can be at a level of Assistant, Associate, or Full Professor, will be available starting August 1990.

The successful applicant must have demonstrated excellence in research, and must exhibit exceptional potential for establishing or have already established an independent research program. The University and the Department will make a substantial commitment in equipment and funds to assist the new staff member in building a research program.

Candidates will also be judged on their ability to participate effectively in the teaching program of the Department. The teaching assignment for the academic year is a one-semester lecture or laboratory course at the advanced undergraduate-graduate level. The starting salary is competitive and dependent upon the experience and qualifications of the applicant. The Department of Biochemistry has 15 full-time faculty members and 5 faculty members from allied areas serving with joint appointments. There are approximately 130 doctoral students, 30 postdoctoral fellows, and 200 undergraduate biochemistry majors in the Department

Applications and requests for further information should be directed to. **Professor Robert B. Gennis, Chairman, The Biochemistry Search Committee, Department of Biochemistry, University of Illinois, Box 15 Noyes Laboratory, 505 South Mathews Street, Urbana, Illinois 61801,** Telephone: (217) 333–9075.

Applicants should submit a curriculum vitae, with a list of publications and a brief description of future research plans, and should have letters of recommendation from three qualified scientists sent to the Search Committee. Completed applications should be received by January 1, 1990, in order to receive full consideration.

The University of Illinois is an Affirmative Action/Equal Opportunity Employer. (NW4458)A

AFRC INSTITUTE OF ANIMAL PHYSIOLOGY AND GENETICS RESEARCH EDINBURGH RESEARCH STATION

TWO MOLECULAR BIOLOGISTS

PROJECT LEADERS: ANIMAL DEVELOPMENT

The Research Station occupies new laboratories near Edinburgh and carries out basic research in animal genetics, molecular biology, physiology and development There are close links with the Biology Departments of the University of Edinburgh and the Institute's Research Station at Babraham, Cambridge

The Research Station is continuing to expand its programme and two permanent posts are available within the field of molecular genetics of mammalian/chicken development; this work is complemented by a large programme in transgenic biology.

1. **A MOLECULAR GENETICIST** is required to provide scientific leadership in the Head of Station's laboratory. Current projects include the molecular analysis of the role of growth hormone, insulin-like growth factors and their receptors and polyamine synthesis in muscle growth in chickens and mice This work takes advantage of the availability of animals with large genetic differences in growth rate and transgenic mice. Technical assistance is available. Contact. Dr Grahame Bulfield, 031 440 2726.

2. **A MOLECULAR BIOLOGIST** is required to initiate a research programme on the mechanism of sex determination in birds. The experimental approach is flexible, although an interest in the role of anti-mullerian hormone and/or transcriptional factors may be an advantage Technical assistance is available Contact: Dr Peter Sharp, 031 440 2726

QUALIFICATIONS A first or upper 2nd class honours degree in a relevant discipline is required: 2 years post qualifying experience is required for entry at HSO level and 5 years post qualifying experience for entry at SSO level, a Ph.D in molecular genetics would be an advantage.

SALARY: in scale £10,678-£14,909 HSO grade, 22 days annual leave, or in scale £13,254-£18,864 SSO grade, 25 days annual leave

APPLICATION FORMS (specify which post) can be obtained from **Mrs L Hunter, AFRC, Institute of Animal Physiology and Genetics Research, Edinburgh Research Station, Roslin, Midlothian EH25 9PS,** and should be completed and submitted together with a CV and publication record by 27th November 1989. (1950)A

GLAXO INSTITUTE FOR MOLECULAR BIOLOGY

The Geneva biotechnology research unit of the largest U.K. pharmaceutical group is recruiting

CELLULAR-IMMUNOLOGIST

to study the role of cell surface membrane molecules in adhesion and extravasation

The successful applicant will be expected to contribute substantially to driving the cell biology research in this program and will interact closely with molecular biologists in the research team. The ideal candidate will have a PhD and several years of postdoctoral experience with a significant publication record. Additional experience in related disciplines would be an advantage.

The Glaxo Institute for Molecular Biology carries out basic long term innovative research directed to facilitate the process of drug discovery. The Institute has an international staff of over one hundred, grouped in small multidisciplinary teams.

We offer an excellent salary and benefits package, with opportunities for career development in one of the most attractive parts of Europe.

If you are interested in this position, please send your Curriculum vitae with a list of publications and the names of three references to : Rita Gloor, Personnel Manager, GLAXO IMB S.A., 46, route des Acacias, 1211 Geneva 24, Switzerland.

(W6633)A

INSTITUTE OF OPHTHALMOLOGY
DEPARTMENT OF PATHOLOGY
GRADUATE OR POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the position of graduate or postdoctoral research assistant to work on the medical control of scar tissue formation with particular reference to glaucoma surgery. The position requires aspects of tissue culture, biochemistry and electron microscopy and is funded by Action Research for the Crippled Child and the British Council for the Prevention of Blindness. The work involves the investigation of mechanisms of fibroblast invasion including migration, proliferation, contraction and synthesis. In addition analysis of extracellular fluids for growth factors and chemoattractants will be undertaken. The successful applicant will work with a small team of researchers investigating the pharmaceutical manipulation of wound healing. The appointment will be for two years and can be made on either the University 1B scale (starting at £9,816 plus £1,650 LA) for graduates or 1A scale (starting at £10,458 plus LA) for those with a PhD.

Applications with a c.v. and the names and addresses of two referees should be sent to:— **Professor Ian Grierson, Department of Pathology, Institute of Ophthalmology, 17-25 Cayton Street, London, EC1V 9AT.** (1920)A

PROFESSOR OF BIOCHEMISTRY AND CHAIR
DEPARTMENT OF BIOCHEMISTRY
SCHOOL OF MEDICINE,
EAST CAROLINA UNIVERSITY

Nominations and applications are invited for the position of Professor and Chairperson of the Department of Biochemistry at the East Carolina University School of Medicine. The department is responsible for the education of medical and graduate students and consists of 9 tenured or tenured-track faculty. The department is well-funded and well-equipped. We are seeking candidates with an outstanding record of achievement in any field of biochemistry or molecular biology to provide strong leadership to an excellent department. Candidates should have a doctorate in biochemistry or a related discipline, experience in an academic medical center and a record of scientific excellence. Candidates should submit a curriculum vitae and the names and addresses of three references to: **Dr. Wallace R. Wooles, Chairman, Biochemistry Search Committee, Department of Pharmacology, East Carolina University School of Medicine, Greenville, North Carolina 27858.** Applications should be received by February 1, 1990. East Carolina University is an Equal Opportunity Employer and encourages the application of women and minorities. (NW4409)A

FACULTY POSITION IN VISUAL SYSTEM NEUROPHYSIOLOGY

The UCLA Psychology Department seeks a (tenure-track) faculty member engaged in research on central nervous system processing of visual information. Applicants must have a strong background in single unit electrophysiology and their research should be directed toward understanding the neural computations leading to perception and pattern recognition. Although we expect to hire a visual system physiologist, applicants working on other senses will be considered. Please send a curriculum vita and have three letters of reference sent to: **Physiological Search Committee (F.B. Krasne, Chair), Department of Psychology, UCLA, Los Angeles, CA** 90024–1563. A typical reprint would also be welcome. Deadline for receipt of applications and letters of reference is January 1, 1990. *The University of California is an Equal Opportunity/Affirmative Action Employer.* (NW4439)A

POSTDOCTORAL POSITIONS

In the Department of Microbiology, University of Texas at Austin, Austin, TX 78712.

Topics: (1) Site-specific recombination DNA-protein interactions and catalytic mechanism; (2) Photoregulation and development regulation of gene expression

Experience in protein biochemistry and enzymology desirable

Apply to. **Dr. Makkuni Jayaram, Dept Molecular Biology, MB-3, Research Institute of Scripps Clinic, 10666 N Torrey Pines Road, La Jolla, CA 92037,** (619) 554–8009 EOE/AA. (NW4388)A

Postdoctoral Position
YALE UNIVERSITY
Gene targeting of cellular oncogenes

Applications are invited to join genetic studies using targeted homologous recombination in tissue culture model systems aimed at elucidating the function of proto-oncogenes (*c-myc, c-raf,* and *rb*) in normal cellular physiology.

(NW4451)A

Asthma Research in Sandoz, Basle/Switzerland

The asthma research programme at Sandoz seeks to relate clinical experience of anti-asthma drugs to the pharmacology of laboratory mammals when subjected to acute provocation stimuli (allergen, cytokines, PAF, or pharmaceuticals) or to chronic exposure (asthmatic chemicals, PAF, allergens or infectious agents). Measurements of pulmonary function, eosinophil accumulation, mucociliary clearence and novel tests involving platelet activation are used for drug evaluation. Considerable emphasis has been given to electronic capture and processing of data, so that work stations are integrated as a local area network and will be linked to complementary laboratories within Switzerland and Japan. A primate laboratory equipped to clinical intensive care standards has been established in order to relate preclinical research to clinical pharmacology and a long term collaborative relationship has been initiated with a clinical research group specialising in asthma, based in the Swiss Institute of Allergy and Asthma Research in Davos.

An opportunity has arisen for an

experienced scientist

to join preclinical asthma research.

Applicants (aged less than 35 will be expected to direct research projects and hence should have undertaken a period of independent post-doctoral research.

Applications including curriculum vitae should be sent to:

(W6634)A

FACULTY POSITION: The Marine Sciences Research Center (MSRC), SUNY Stony Brook, is accepting applications for an assistant professor position within the Center's Living Marine Resources Institute (LIMRI). Candidates are sought with a strong background in the population biology of commercially-and/or recreationally-exploited marine species. We are most interested in individuals with expertise in population dynamics and/or in shellfish biology. However, we encourage applicants from other specialized fields, such as genetics, behavioural biology, physiological ecology, etc. This is tenure-track position, with an initial three-year appointment. Starting salary is $31,500–$33,500 for the academic year, which may be supplemented by up to 28% of the academic year salary for summer salary through grants and contracts. The MSRC is the center for research, graduate education, and public service in the marine sciences for the State University of New York system and is a comprehensive coastal oceanographic institution. Applicants should send a complete resume, statement of research goals, and three letters of reference by 22 December 1989 to: **William M. Wise, Marine Sciences Research Center, SUNY Stony Brook, NY 11794–5000.** *SUNY Stony Brook is an affirmative action/equal opportunity educator and employer.* AK 256.

(NW4453)A

Assistant Professor Molecular Biology/Genetics

Franklin and Marshall College invites applications for a tenure-track position as Assistant Professor, to begin August 1990. Applicants should have a broad background in biology with extensive training in molecular biology and an active interest in both research and teaching. The successful applicant will teach an upper level course in molecular biology and participate in teaching genetics and introductory biology. Start-up funds and a well-equipped molecular biology research laboratory are available. Curriculum development and research are also supported by a major grant from the Howard Hughes Medical Institute.

Send curriculum vitae, graduate and undergraduate transcripts, and statements of research and teaching interests by December 15, and have letters of recommendation sent to: **Dr. David King, Department of Biology, Franklin and Marshall College, Lancaster, PA 17604-3003.**

The College is committed to cultural pluralism through the hiring of women and minorities. An Equal Opportunity Employer.

(NW4449)A

ECOLOGICAL ANTHROPOLOGIST

University of Georgia, Department of Anthropology and Linguistics, announces a newly created program in ecological anthropology and invites applications for a tenure-track position as Professor and Head of the department from scholars of recognized distinction with primary interests in ecological anthropology. Salary competitive. The individual chosen will play a major role in the development of the ecological anthropology program and the selection of the successful candidates for two tenure-track positions in ecological anthropology. The new Head will also work closely with the University of Georgia's Institute of Ecology. Deadline for applications is December 15, 1989. The University of Georgia is an equal opportunity, affirmative action employer. Women and minority candidates are encouraged to apply. Candidates should send a letter of applications, vita, and names of four referees, to **Chair, Search Committee, Department of Anthropology and Linguistics, University of Georgia, Athens, GA 30602, U.S.A.** *EOE/AAE.* (NW4456)A

ROYAL HOLLOWAY AND BEDFORD
NEW COLLEGE
University of London

SCHOOL OF LIFE SCIENCES

POSTDOCTORAL AND POSTGRADUATE RESEARCH POSITIONS

1. Post-Doctoral neurobiologist

A postdoctoral neurobiologist is required for a three year SERC-funded project supervised by Drs. M C. Thorndyke and P.W. Beesley. The aim of the project is to study molecular aspects of regeneration in the neural ganglion of the ascidian *Ciona intestinalis* The unique feature of this system is that the neural ganglion can completely regenerate in 4-6 weeks, making this an ideal model system for studying many of the molecular aspects of neuronal regeneration

The project will involve immunochemical and in vitro culture techniques as well as the use of cell-type specific monoclonal antibodies and radiochemical markers to study cell lineage. Experience in these areas would be an advantage but the main requirement is for a well motivated candidate with a strong commitment to fundamental research. Informal enquiries welcomed. Contact Dr M.C Thorndyke (Department Biology tel· 0784 434455 Ext 3766 or Dr P.W. Beesley (Biochemistry) Ext 3546.

2. Research Assistant in Endocrinology/Cell Biology

A postgraduate research assistant is required to work on a SERC-funded project supervised by Dr M C. Thorndyke on the regulation of secretory activity in isolated fish gastric oxyntopeptic cells

The project seeks to investigate the role of neurohormonal peptides (bombesin, gastrin, CCK, substance P) in the differential control of acid and pepsin secretion The fish stomach includes a discrete population of secretory cells which produce both pepsin and acid (the oxynto-peptic cells) and the major aim of the project will be to develop an isolated oxyntopeptic cell preparation with which to study the neurohormonal regulation of secretory activity. Informal enquiries welcomed. Contact Dr. M.C. Thorndyke tel: as above. The appointment will be for one year in the first instance

The successful applicants will join an active Life Sciences research group studying selected aspects of Cell Recognition and Neurobiology

We anticipate a starting date for both positions early in 1990. The appointments will be at the lower end of the RAIA scale for the postdoctoral position (£10,458-16,668) and RAIB scale for the postgraduate position (£9,816-12,381) both plus £1,650 a year London allowance Formal applications for these two positions with the names and addresses of two academic referees should be submitted not later than 1st December 1989 to the **Personnel Officer, Royal Holloway & Bedford New College, Egham Hill, Egham, Surrey TW20 0EX.** (1945)A

PHARMACOLOGISTS

UNIVERSITY OF TORONTO

The Department of Pharmacology, Faculty of Medicine, University of Toronto invites applications for 3 tenure-track Assistant Professorships from individuals well-qualified to establish an independent first-class research program in one of the following areas:

1. Molecular biology of receptors/signal transduction/ 2nd messengers
2. Cellular/molecular toxicology
3. Molecular biology/genetics of drug metabolism

Successful applicants will have promise in teaching as well as in research and will be expected to teach some portion of pharmacology to students in undergraduate, graduate, or professional (medical/dental) courses and to train graduate students. Qualifications should include a Ph.D. or M.D. degree with postdoctoral research experience. The starting date is July 1990 with some flexibility if necessary. Applications should include a complete curriculum vitae, a letter stating current and intended research interests and the names of at least three referees. Please indicate which of the 3 specific positions you are seeking. Apply before 15 January 1990 to: **Dr. Allan B. Okey, Professor and Chair, Department of Pharmacology, Medical Sciences Building, University of Toronto, Toronto, Ontario, Canada M5S 1A8.**

Both men and women are encouraged to apply. In accordance with Canadian immigration requirements priority will be given to Canadian citizens and permanent residents of Canada. (NW4461)A

RESEARCH OFFICER/ POSTDOCTORAL FELLOW

A Molecular Biologist is required to join a vigorous Immunology research team involved in the characterisation and cloning of genes of cytokines affecting macrophage function. Expertise in gene cloning techniques is essential. A lateral thinker with broader interests in cellular immunology would find this position stimulating.

The Heart Research Institute is a recently established modern facility comprising five major groups with interests in cell biology, immunology, molecular biology, biochemistry and coagulation with particular emphasis on mechanisms of atherogenesis. Applications are invited from persons holding PhD or equivalent. The position will be available from January 1990 for an initial period of three years. Salary is in accordance with NH & MRC scales. Further information is available on request. Applications close 30th November, 1989.

Written application should be sent to **Dr. Carolyn Geczy, Heart Research Institute, 145 Missenden Road, Camperdown, NSW 2050, Australia (Fax +61 (2) 550 3302).** Include detailed CV, contact number (phone and FAX) and names and addresses of 3 referees. (W6446)A

MASSEY UNIVERSITY
Palmerston North, New Zealand

LECTURER IN BIOCHEMISTRY

Applications are invited for the above position in the Department of Chemistry and Biochemistry. The appointee will be expected to contribute to the undergraduate and graduate teaching programme of the department and carry out an active research programme

The department is particulary interested in applicants who have a research interest in metabolic or physiological biochemistry or in the application of recombinant DNA technology to protein structure and function. Candidates with a good research record in other fields will be considered.

Information about the department and its activities is available from Dr J C Hawke, Head of Department.

Salary: NZ$36,000-NZ$47,200.

Further information and conditions of appointment may be obtained from Appointments (37047), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF, or from Mrs V B Bretherton, Personnel Section, Massey University, Palmerston North, New Zealand, with whom applications, including a full curriculum vitae and the names of three referees, close on *8 December 1989* (W6636)A

THE UNIVERSITY OF LEEDS
Department of Chemical Pathology and Immunology

LECTURER (NON CLINICAL) (NAAS)

Applications are invited for the above post which is available immediately.

Candidates should have a PhD in biochemistry, immunology or a related subject, together with suitable postdoctoral experience and will be expected to establish a research team working in the application of molecular biology, biochemistry or immunology to medicine

Salary on the scale for Lecturer Grade A (£10,458–£15,372) or exceptionally Grade B (£16,014–£20,469) according to qualifications and relevant experience.

Informal enquiries may be made to Professor Whicher (tel 0532 335673)

Application forms and further particulars may be obtained from and completed applications forwarded to the **Registrar, The University, Leeds LS2 9JT** (tel 0532 333969) quoting reference no. 84/24 *Closing date for applications 22nd October 1989.*

(1946)A

POSTDOCTORAL POSITION

One year postdoctoral position, (with annual renewal depending on performance) to study RNA metabolism. Qualified candidate must possess Ph.D. in biochemistry or molecular biology with experience in DNA cloning and RNA Salary $20,000 per annum Please forward résumé to **Civilian Personnel, Henry M. Jackson Foundation, 4301 Jones Bridge Road, Bethesda, MD 20814–4799** (NW4346)A

THE UNIVERSITY OF LEEDS

Department of Physics

CHAIR OF PHYSICS

Applications are invited for a new Chair in the Department of Physics which has been created following the appointment of Professor I M Ward, FRS, to the Directorship of the IRC in Polymer Science and Technology. The post is available from 1 October 1990. Candidates will be expected to have a proven and well supported record in an area of physics which lends itself to practical application and exploitation. The successful applicant will be required to lead a new research group within the Department; a Lectureship is associated with the Chair

The salary will be within the professorial range

Further particulars may be obtained from The Registrar, The University of Leeds, Leeds LS2 9JT, quoting reference number 52/54. Applications (two copies) giving details of age, qualifications and experience should reach the Registrar not later than 1 December 1989. Applicants from overseas may apply in the first instance by telex (556473 UNILDS G) or FAX (Group 2/3 (0532-334123 or 336017) naming three referees, preferably at least one in the United Kingdom. (1909)A

POSTDOCTORAL FELLOWSHIP (Skin Vascularization)
RESEARCH STUDENTSHIP (Molecular Biology/Biochemistry)
AND
RESEARCH ASSISTANTSHIP (Technician)

We have three new vacancies in the group to work on the control of blood vessel formation i.e. angiogenesis Angiogenesis is important (e g in cancer, diabetic retinopathy, psoriasis, rheumatic arthritis, wound healing etc) but its molecular mechanisms remain unknown.

Postdoctoral fellow (salary up to £16,000 pa) is funded by a pharmaceutical company and after 2 years by mutual agreement, will lead to a tenured position The pathobiology of skin vascularization in human and *in vitro* and *in vivo* animal models is the underlying theme of this work

The *student* will receive a bursary of approximately £5,500 pa tax free (CRC rate) and is expected to have a good honours degree in an appropriate science subject.

The post of *Research assistant* (salary approximately £10,000 pa) will suit someone with a degree and some experience in biochemistry/cell or molecular biology.

Please send your CV together with the names of 3 referees to **Mrs P Jones, Clinical Research Laboratories, Christie Hospital, Manchester M20 9BX, England.** (1908)A

LITHOSPHERIC PROCESSES
UNIVERSITY OF MARYLAND, COLLEGE PARK

The Lithospheric Processes Group of the Department of Geology, University of Maryland, College Park, invites applications for

Faculty Positions in Radiogenic or Stable Isotope Petrology

Higher education in Maryland has recently undergone reorganization, and the College Park campus has been officially designated as the flagship campus of the University of Maryland system. The growth and development of geology at College Park is part of this overall plan The Department offers B S., M S., and Ph D. degrees Research in the Lithospheric Processes Group is conducted in the areas of tectonics, igneous and metamorphic petrology, experimental petrology and mineralogy, economic geology and geochemistry, Further, there are numerous federal and private laboratories in the Washington, D.C. area including USGS National Center, NASA, DTM, Geophysical Laboratory, NIST (NBS) and the Smithsonian Institution

Appointments will begin August, 1990 The Ph.D. is required. The rank and salary are open, but our preference is to appoint at a junior level. The successful candidates will be expected to develop strong research and teaching programs Applicants should send a detailed resume, a statement of research and teaching interests and the names of three references to **Chair, Lithospheric Processes Search Committee, Department of Geology, University of Maryland, College Park, MD 20742.** For full consideration, applications should be received by February 1, 1990 *The University of Maryland is an equal opportunity/affirmative action employer. Women and minority candidates are encouraged to apply.* (NW4446)A

AFRC INSTITUTE FOR GRASSLAND AND ANIMAL PRODUCTION

WELSH PLANT BREEDING STATION
ABERYSTWYTH

PLANT MOLECULAR BIOLOGIST/CELL BIOLOGIST

Applications are invited for the permanent post of Higher Scientific Officer in the Cell Biology Department to lead a project concerned with modifying the responses of perennial grasses to environmental stress, particularly extremes of temperatures, by the application of genetic manipulation procedures.

Qualifications.
First or upper second class honours degree in Botany, Genetics, Biochemistry or an appropriate related subject with at least two years' post-graduate experience in molecular biology or cell biology.

Terms & Conditions.
Salary scale: £10678-£14909.
Non-contributory superannuation scheme
Annual leave· 25 days plus 10.5 Public & Privilege holidays per annum.

Written requests for further particulars and application form should be made to the Secretary, AFRC Institute for Grassland & Animal Production, Welsh Plant Breeding Station, Plas Gogerddan, Aberystwyth, Dyfed. SY23 3EB. (Quote Ref. 89/15).

Closing date: 17 November 1989.

The AFRC is an Equal Opportunities Employer. (1924)A

MONASH UNIVERSITY
DEPARTMENT OF MATHEMATICS
CONTINUING LECTURER

Preference given to candidate with strong research interests in the numerical solution of the fluid dynamics problems occurring in astrophysics. Appointee will join a group of applied mathematicians working on cosmology, star formation and relativistic flow problems. Computing facilities include access to a Cray XMP and Silicon Graphics workstations and a Centre for Computational Mathematics has been formed to support research on computationally demanding scientific problems. Other research areas include general relativity and geophysical fluid dynamics Salary $A31,259-$A40,622 p.a. Enquiries to Professor J. J. Monaghan phone (03) 565 4463. Applications including Ref. no. 40112C, curriculum vitae and 3 referees to the Registrar, Monash University, Clayton, Victoria, Australia 3168 by 14/12/89

AN EQUAL OPPORTUNITY EMPLOYER
(W6335)A

POST DOCTORAL POSITION (ASSISTANT RESEARCH SCIENTIST)
AVAILABLE SPRING 1990

in Laboratory of Dr. Claudio Basilico, Department of Pathology Areas of research presently investigated include: 1) The regulation of expression of the K-FGF/HST oncogene, and the characterization of the growth factor it encodes. 2) The interaction of K-FGF and related growth factors with their receptor(s) 3) Cloning and characterization of genes regulating cell cycle progression in animal cells. Background in Molecular Biology, Genetics or Cell Biology desirable. Salary open. Send CV and names of references to: **Joan Harmon, Personnel Department, NEW YORK UNIVERSITY MEDICAL CENTER, 550 First Ave., New York, NY 10016.** *An Equal Opportunity Employer M/F* (NW4428)A

RESEARCH ASSOCIATE

Brigham & Women's Hospital has an opening for a research associate to study electrophysiology of smooth muscle Applicant should have experience with in-vivo experimentation, chronic animal preparations and basic physiological techniques Experience with patch clamp technique welcome.

Candidates should have a Ph.D. in a related field and capacity for interdisciplinary research and growth. Please send resume, letter of interest and names of references to: **D.S. Sugarbaker, M.D., Department of Surgery, Brigham & Women's Hospital, 75 Francis Street, Boston, MA 02115.** (NW4404)A

POSTDOCTORAL RESEARCH POSITION IN NEUROANATOMY

A position is available immediately to investigate the magnetic properties of the human brain. Qualifications include a PhD with a strong background in anatomy, physiology, or cell biology. The techniques used are similar to those involved in studies of rock magnetism, and a willingness is required to learn and apply these techniques to the problem of characterizing ferromagnetic particles in the brain. Please send curriculum vitae and the names of three references to· **Dr. Joseph L. Kirschvink, Caltech 170-25, Pasadena, California 91125** *The California Institute of Technology is an equal-opportunity/affirmative-action employer Applications are encouraged from qualified women and minority candidates.* (NW4432)A

nature
— the professionals' choice

UNIVERSITY OF OXFORD

MEDICAL RESEARCH COUNCIL ANATOMICAL NEUROPHARMACOLOGY UNIT

Postdoctoral Research Positions

MRC Non-clinical Scientific Staff (Electrophysiologist Grade II)

To join a group whose goal is to understand the structure and function of local circuits in the cerebral cortex in sufficient detail to build a realistic model cortex. A very wide range of techniques are in daily use, ranging from extracellular and intracellular recordings *in vivo* and *in vitro*, physiological and histological studies of the neurochemistry of identified nerve cells, tracing of the connections of single nerve cells at light and electron microscopic levels, and computer modelling of the electrical properties of single cells and neural networks (see Martin, K.A C. (1988) Q J Exp. Physiol. 73, 637). The laboratory has developed a strong base in contemporary computer technology for all aspects of the research. There are rich collaborative opportunities both within the Unit and with groups in Europe and the USA The successful candidate will be given ample opportunity to develop projects within this framework and will be encouraged to learn appropriate new skills. Remuneration on the scale for university non-clinical academic staff up to a maximum of £15,372 *per annum*, depending on age.

Neuromorphologist Grade IA

To join the above group, studying the development and modification of circuits in the cerebral cortex. The projects are centred on the functional and morphological development of identified nerve cells and the synaptic connections they make in the visual cortex, with the goal of understanding the development and plasticity of neocortex at the cellular level (see Friedlander & Martin (1989) J. Physiol. 416, 183) Techniques include neurochemistry, light and electron microscopy, and computer-based reconstruction of nerve cells. Requisite skills can be acquired on site. The current projects, funded by the Wellcome Trust, involve collaborations with physiologists, microscopists, neurochemists and computer modellers within the Unit, Europe and the USA, and the successful candidate will be encouraged to use these opportunities in his/her own projects Remuneration on the university scale up to a maximum of £16,665 *per annum*, depending on age.

Both postholders would work with Dr Kevan A C. Martin from whom further particulars can be obtained and to whom applications (CV and names of two referees) should be sent. **MRC Anatomical Neuropharmacology Unit, Department of Pharmacology, South Parks Road, Oxford OX1 3QT (TEL 0865 275179, FAX 0865 275161).**

Closing date: 30 November 1989

EQUAL OPPORTUNITY EMPLOYERS (1957)A

UNIVERSITY OF ZIMBABWE

Applications are invited for the following posts:

ASSOCIATE PROFESSORSHIPS/ SENIOR LECTURESHIPS/LECTURESHIPS

Department of Physics (BTech Programme)
(4 Posts)

Appointees will teach general physics plus one of: Electronics and Instrumentation; Exploration Geophysics; Atmospheric Physics and Meterology; Medical Physics.

CONDITIONS OF SERVICE

Salary Scales: Lecturer: Z$19,860–Z$28,176; Senior Lecturer: Z$29,124–Z$31,572; Associate Professor: Z$32,532–Z$33,624. Appointment on the above scales will be according to qualification and experience.

Both permanent and short-term contracts are offered. Persons who are not Zimbabwean citizens may be appointed only on a short-term contract basis for an initial period of two years. Short-term contracts may be extended. Applicants should quote reference number ASA/16/9/89 and submit six copies of applications giving full personal particulars which should include full name, place and date of birth, qualifications, employment and experience, present salary, date of availability, telephone number and names and addresses of three referees to the **Deputy Registrar (Administration), University of Zimbabwe, PO Box MP 167, Mount Pleasant, Harare, Zimbabwe.** Telegrams: UNIVERSITY; Telex: 4–152 ZW Applicants from outside Zimbabwe should also send a copy to the **Appointments Officer, Association of Commonwealth Universitites, 36 Gordon Square, London WC1H 0PF, UK,** from whom further details may be obtained.

Closing date for receipt of applications is *17 November 1989.*

(W6642)A

The University of Manitoba
Faculty of Science

GEOLOGICAL SCIENCES

The Department of Geological Sciences, University of Manitoba has tenure-track opening in geophysics at the assistant professor level, beginning July 1, 1990, or as soon as possible thereafter. Applicants must have a Ph.D. in geophysics at the time of appointment. Primary research areas include electromagnetics, geodynamics, and seismology. Outstanding candidates in other fields will be considered. The successful candidate will be expected to develop an independent research program, have a strong interest in undergraduate and graduate teaching, and complement the ongoing research programs of other faculty members in the department. The department has 16 full-time faculty members and offers Honours B.Sc., M.Sc. and Ph.D. programs in geophysics and geology. Salary dependent on qualifications and experience. Both women and men are encouraged to apply. In accordance with Canada Immigration, priority will be given to Canadian citizens or permanent residents. Please send applications, curriculum vitae, and the names of three referees to: **Professor G.S. Clark, Head, Department of Geological Sciences, University of Manitoba, Winnipeg, Manitoba, R3T 2N2, Canada.** Applications should be received by December 31, 1989. (NW4460)A

RESEARCH SCIENTIST/ Biological Sciences Center

The Desert Research Institute is accepting applications for a Research Scientist to design and develop a plant physiological ecology teaching and research program emphasizing plant-atmosphere interactions, ecological toxicology, and plant population biology/genetics. Successful candidate will be required to interact with and develop inter-disciplinary teaching and research programs within the University of Nevada System and with other professionals in government, industry, and education The position is 80% research and 20% teaching. Requirements include. Ph.D. in Population Biology/Plant Physiology; 10 or more years experience beyond the Ph.D. in conducting air population-plant population/genetics, plant physiological/genetics, and plant physiological effects research; 4 or more years experience in managing physiological ecology research, a strong publication record, and the proven ability to attract research funding. Salary and rank commensurate with qualifications, excellent benefit package. Applications must be received by Nov. 30, 1989. Additional information may be obtained from Dr. Carl Fox (702) 673-7322. To apply, send curriculum vitae, names of three references, and letter of interest to: **Personnel Office, Desert Research Institute, P.O. Box 60220, Reno NV 89506.** *An Affirmative Action/Equal Opportunity Employer.* (NW4464)A

UNIVERSITY OF LIVERPOOL

Chair of Oceanography

Applications are invited for the Chair of Oceanography to be held in the Department of Earth Sciences

Applications will be welcomed from candidates working in the fields of physical/dynamical oceanography, marine geochemistry or marine geology.

The salary will be within the range approved for non-clinical professorial salaries, at present not less than £25,919 per annum, and, initially will depend on the qualifications and experience of the successful candidate.

Prospective applicants are invited to contact Professor A.L. Harris, Tel. 051-794 5145.

Applications, together with the names of three referees, should be received not later than 31st December, 1989, by **The Director of Staffing Services (AS), The University, P.O. Box 147, Liverpool, L69 3BX,** from whom further particulars may be obtained.

An Equal Opportunity Employer (1947)A

AFRC Institute of Engineering Research

PROJECT LEADER

AFRC Institute of Engineering Research, sited in rural parkland, is internationally renowned for innovation in engineering and scientific research applied to agriculture and food. We now require a dynamic research leader to pioneer food engineering research (especially mixing studies) within the Chemical Engineering Group. The post holder will be responsible not only for supervising work on discharge of liquid/solid mixtures from hoppers but also for developing his/her own research on modelling the performance of mixers for free flowing and cohesive particulate materials.

Candidates should have a First or Upper Second Class honours degree in Chemical Engineering or another branch of Engineering or in a Natural Science, or equivalent qualification with at least four years' post-graduate research. For appointment at the higher grade considerable and relevant post-graduate research is required.

The post is graded Senior Scientific Officer/Unified Grade 7.

Salary scale.	Senior Scientific Officer	£13,254 - £18,864
	Unified Grade 7	£13,360 - £22,606

Performance related increments.
Non-contributory Superannuation Scheme

Assistance with re-location expenses may be available.

Further details and an application form from **The Personnel Office, AFRC Institute of Engineering Research, Wrest Park, Silsoe, Bedford MK45 4HS. Telephone: 0525 60000.**

AFRC Engineering is an Equal Opportunities Employer. (1958)A

WEIZMANN INSTITUTE OF SCIENCE
Rehovot 76100 Israel

OPENINGS FOR SCIENTISTS

The Weizmann Institute of Science is now offering a limited number of temporary appointments to the position of Scientist

Candidates must have completed two years of post-doctoral work.

Appointments will be made in all the areas of scientific research at the Institute.

Life sciences **Physics**
Chemistry **Mathematics**
Science teaching

Appointments are for a period of one year. However, they may be extended for a period not to exceed 5 years from receipt of Ph.D degree (or equivalent) Successful appointees will be eligible to apply for promotion to the position of Senior Scientist.

Financial renumeration for a Scientist is at the level of Lecturer and includes all of the associated benefits. In addition, a relocation stipend is provided.

Application forms and additional information may be obtained from:

The Feinberg Graduate School
The Weizmann Institute of Science
Rehovot 76100, Israel

Applications are reviewed twice each year: January 1 and May 15 (W6458)A

dkfz

A post-doctoral position is immediately available in the

Division of Immunogenetics (Prof. Dr. P.H. Krammer)

of the Institute for Immunology and Genetics at the German Cancer Research Center, Heidelberg/FRG to investigate the rôle of cell surface molecules in growth control of normal and malignant lymphocytes. Biologists and/or M.D.'s with experience in cellular immunology, immunochemistry and/or molecular biology preferred.

Send applications and the names of two referees to: **Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, D-6900 Heidelberg. Tel. 1949–6221–484717.** (W6450)A

JCU JAMES COOK UNIVERSITY OF NORTH QUEENSLAND

Townsville, Australia

CHAIRS

Department of Civil and Systems Engineering

Following the retirement of Professor D H Trollope (the Foundation Professor of Civil Engineering and former Head of Department) and the untimely death of Professor K P Stark (the Foundation Professor of Systems Engineering and recently Head of Department), the University is seeking to fill both chairs now vacant in the Department of Civil and Systems Engineering.

The Department, which was established in 1961 as part of the then University College of Townsville, is a dynamic one which has earned an international reputation for its contributions in a number of areas including geomechanics, cyclone engineering, coastal engineering, groundwater engineering and systems engineering. The Department has strong contacts with industry and other groups outside the University In addition to its civil and systems engineering activities, the Department is presently fostering developments in mechanical engineering and building with a view to the establishment of two new departments covering these fields

Applications are now invited from suitably qualified persons with international reputations for research and scholarship for the following chairs in the Department.

CHAIR OF CIVIL ENGINEERING

The appointee will also be appointed as Head of the Department of Civil and Systems Eng neering for a five year term.

Applicants will be expected to have a PhD in Civil Engineering and must have a high level of expertise and achievement in one of the areas of structures, hydraulics or geomechanics

In addition to providing strong academic leadership in the appointee's specialist area a commitment to fostering the Department's broad range of activities is required.

Reference No 89155

THE KEVIN STARK CHAIR OF SYSTEMS ENGINEERING

Applicants will be expected to have a PhD in a relevant field and must have a high level of expertise and achievement in Systems Engineering. Experience in numerical modelling, particularly outside traditional engineering applications (such as marine environmental areas) is also required Qua ifications and/or experience in related areas such as economics, operations research, marine science and computer science will be well regarded.

The appointee will be responsible to the Head of the Department of Civil and Systems Engineering for providing strong academic leadership in Systems Engineering including a commitment to continuing the multidisciplinary systems engineering activities that have been undertaken successfully to date, particularly in the areas of environmental studies, transportation and energy systems and marine science.

Reference No. 89156

General Information

Initial enquiries regarding the duties of the position may be made in confidence to Dr B S Best, Head of the Department of Civil and Systems Engineering, on (077) 81 4270, or by FAX to (077) 75 1184.

The salary rate for Professor is currently A$63,919 a year.

Applications close on *30 November 1989.*

Further particulars and application forms are available from the **Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF,** or from the **Registrar, James Cook University of North Queensland, Townsville, Qld 4811, Australia.** (W6455)A

Molecular Genetics/ Circadian Rhythms

We use classical and molecular genetics to study the molecular mechanism of the circadian clock (*Nature* **333**, 558–562, June 15, 1989 cover article), (*Science* **243**, 385–388, 1989). Exprience w th genetics, biochemistry, and/or recombinant DNA is essential. Please send CV and the names of three references to Prof Jay C. Dunlap, Dept of Biochemistry, Dartmouth Medical School. Hanover, NH 03756. (NW4356)A

Assistant Professor

The Biophysics & Cell Physiology Division of the Department of Molecular & Cell Biology invites applications for a tenure-track faculty position at the Assistant Professor level, the appointment to begin in the 1990-91 academic year, pending budgetary approval. Formed during the recent reorganization of the biological sciences at Berkeley, this new department contains 92 faculty in six divisions.

Applicants should hold a Ph.D. degree, or equivalent, and have had significant research experience in one of the following areas: computation by systems of real neurons, the study of intercellular messengers in nerve cells, or structural molecular biophysics. Candidates should have a demonstrated experimental ability and a strong theoretical background. The duties of this position include: continuing important research, supervision of graduate students and postdoctoral fellows and innovative course design and teaching at the undergraduate and graduate levels. Applications should include a letter specifying qualifications and current research interests, curriculum vitae, a list of scientific publications with representative reprints and the names and addresses of four persons from whom we may request letters of recommendation. Applications must arrive no later than January 15, 1990 and should be addressed to: **Professor W. Geoffrey Owen, Head, Division of Biophysics & Cell Physiology, Department of Molecular and Cell Biology, 102 Donner Laboratory, University of California, Berkeley CA 94720.** *The University of California is an Equal Opportunity, Affirmative Action employer.* (NW4447)A

EXTENSION OF SEARCH

NAMED PROFESSORSHIP IN BOTANY OR MICROBIOLOGY

The Department of Botany and Microbiology at the University of Oklahoma is seeking nominations and candidates for a named professorship in recognition of Dr George Lynn Cross, former president of the University and Chairman of the department. The Department of Botany & Microbiology has 20 faculty members, about 50 graduate students, well-equipped teaching and research facilities and strong externally-funded research programs. The candidate must be an established scholar with research interests in molecular aspects of physiology or a related area of modern biology to further advance the department's research and educational excellence and to help develop biotechnology in the state. Candidates must have a Ph.D. in a life science or related area and possess a distinguished, internationally recognized, and externally-funded research program.

The candidate must submit curriculum vitae, description of current and future research goals and the names of five references. Applications will be accepted until position is filled and reviewed at 2-month intervals starting on January 1, 1990 Application materials and nominations should be sent to: **Dr. Michael J. McInerney, Search Committee, Department of Botany & Microbiology, University of Oklahoma, Norman, Ok. 73019.**

The University of Oklahoma is an equal opportunity/affirmative action employer (NW4466)A

SEISMOLOGIST/BROWN UNIVERSITY

The Department of Geological Sciences at Brown University invites applications for a tenure track position at the **Assistant Professor** level We are looking for an outstanding young scientist within the field of seismology who will complement our existing programs in global dynamics, mid-ocean ridge tectonics, earthquake prediction/fault mechanics, and/or regional studies of tectonically active areas Preference will be given to a candidate who uses a balanced approach combining observation and theory, but primary emphasis will be on the candidate's qualifications as a scientist and potential for innovative research and teaching. The candidate is expected to develo a strong research program with extramural funding and to participate in both graduate and undergraduate teaching.

Applicants should forward a curriculum vitae, description of research and teaching interests, and list of at least three potential referees to: **Donald W. Forsyth, Chair, Search Committee, Department of Geological Sciences, Brown University, Providence, RI 02912.** *Brown University is an equal opportunity/affirmative action employer.* (NW4468)A

APA MONITOR

The School of Human Development at The University of Texas at Dallas announces the availability of four faculty positions in the areas of Cognition and Neuroscience. These appointments will contribute to the School's interdisciplinary graduate programs where we are developing emphases in cognitive neuroscience Responsibilities also include teaching in the undergraduate program in Psychology. Candidates should provide evidence of scholarly productivity and a commitment to graduate education in an interdisciplinary context Appointments will generally be made at the assistant professor level, although one of these positions may be filled at a more advanced level

COGNITIVE SCIENCE — Emphasis on knowledge acquisition and representation, artificial intelligence and expert systems, complex problem solving, human-computer interaction, or text comparison. Academic Search # 548

NEUROSCIENCE — Two positions are open for neurophysiologists or neuroanatomists One with an emphasis in computational neuroscience, neural modeling of behaviour and/or neural circuit analysis. The second position seeks candidates with expertise in neural plasticity, learning, perception or development. Academic Search #.547

AGING AND LANGUAGE — Expertise in brain mechanisms and language processes, including the aphasias, in aging Academic Search # 544

Salary, teaching loads and research support are highly competitive *Indication of sex and ethnicity for Affirmative Action purposes is requested but not required.* Please send letter, curriculum vitae and the names of three references by 15 November 1989 to **Academic Search # , The University of Texas at Dallas, P O. Cambridge

RESEARCH ASSISTANT

Applications are invited from research orientated graduates to work in a research group with Dr. Richard Henderson The research concerns the structure of membrane receptors coupled to G-proteins involved in signal transduction (rhodopsin, ß-adrenergic receptors and related receptors). These molecules all contain seven transmembrane helices and their structure is important for understanding of the action of many existing drugs and for the development of more specific drugs in the future.

Practical work will include membrane receptor protein expression in eucaryotic and procaryotic systems, functional analysis of the products and development of large scale purifications. Candidates will benefit from practical experience in biochemistry and molecular biology.

For more information contact directly Dr Richard Henderson or Dr Gebhard Schertler (phone 0223 248011). Application, including a CV and the names of two professional referees, should be sent by Friday 27 November 1989 quoting reference SS 7196 to:

The Personal Officer,
MRC Laboratory of Molecular Biology,
Hills Road,
Cambridge,
CB2 2QH.

MRC
Medical Research Council

The Medical Research Council is an Equal Opportunity Employer. (1949)A

THE UNIVERSITY OF CALIFORNIA, SAN DIEGO

is recruiting for a position of research psychologist as Assistant Adjunct Professor in the Division of Adolescent Medicine. Applicant will be responsible for identification, implementation, administration, coordination and evaluation of research programs within the division. Identification of pertinent field laboratory projects dealing with Teenage Obstetrics. Candidates should have training in early adolescent social relationships, social support and a person-context fit conceptualization of social competence. Train and provide consultation in psycology for Divisional staff. Applicant must have Ph.D in research psychology. Salary commensurate with experience.

Interested individuals' should send C.V. with a list of 3 references no later than December 1, 1989 to. **Michael M. Kaback, M.D., UCSD/Pediatrics Business Office, M-026, La Jolla, CA 92093.**

The University of California is an Equal Opportunity/Affirmative Action Employer. (NW4469)A

Senior Scientist

A Senior Scientist is needed in the National HIV Reference Laboratory The Laboratory, which was established in 1985, is funded by the Commonwealth Department of Community Services and Health.

The Laboratory is responsible for providing reference services for HIV and related human retroviruses specifically to:

- Evaluate new diagnostic assays for the Commonwealth Department of Health
- Provide a confirmatory testing service for sera referred by State Reference Laboratories
- Develop quality control programmes to monitor the quality of anti-HIV testing in Australia.
- Assist in training personnel, convene workshops for exchanging information on test performance and appropriate testing strategies;
- Collate information on antigen variability, antibody response and such other similar matters as are pertinent to HIV testing.

The position requires a mature person with a strong scientific background, sound administrative skills and the ability to liaise with government, industry and laboratory staff

Salary and conditions are in accordance with the Victorian Hospital Scientists' Award, currently Scientists Grade 3.

Further information can be obtained from Professor Ian Gust (61-3) 488 2388. Fax 61-3-481-3816. Written applications, including names of 3 referees, should be forwarded to the Employee Relations Manager by 23 November, 1989.

Fairfield Hospital

Yarra Bend Road, Fairfield 3087 Australia

UNIVERSITY OF BATH
MOLECULAR GRAPHICS UNIT

POSTDOCTORAL RESEARCH OFFICER

This SERC (Membrane Initiative) funded position is available to explore the use of modern molecular graphics techniques to elucidate constraints on the membrane organisation and topography of the hexose carrier protein. The project will involve computer-aided modelling but there will be facilities available to test model predictions experimentally.

Experience in computers or modelling is not essential and this may be an opportunity for candidates who wish to enter the field of molecular modelling. The candidate will join an active research group of 3/4 postdocs and 2 postgraduates involved in modelling systems from small peptide hormones to the acetylcholine receptor. Funded by SERC and industry, including ICI Pharmaceuticals, Shell Agrochemicals, Fisons and Organon.

The appointment is for up to three years. The salary is in the range of £10,458 per annum to £12,381 per annum.

Application forms may be obtained from the **Personnel Office, University of Bath, Claverton Down, Bath BA2 7AY** or 'phone Bath (0225) 826095 quoting ref no: 89/327. Closing date: 23.11.89 Further information may be obtained from Dr D Osguthorpe, School of Chemistry (0225 826116) or Dr G D Holman, Biochemistry Department (0225 826874) (1923)A

University of Cambridge
Department of Biochemistry

SERC Molecular Recognition Centre

Physical Biochemistry of Protein Electron Transfer

Applications are invited for a postdoctoral research associateship to study the interaction between plastocyanin and cytochrome by NMR, stopped flow spectrophotometry and other techniques. A series of mutant plastocyanins are being prepared in collaboration with Dr. J C. Gray. The post is available for up to 3 years with a salary in the range £10,458-£15,372 p.a. according to age and experience.

Applications (with curriculum vitae and names of two referees) should be sent to **Dr. D.S. Bendall, Department of Biochemistry, Tennis Court Road, Cambridge, CB2 1QW,** as soon as possible. Further details from Dr. Bendall Tel: (0223) 333631).

THE UNIVERSITY FOLLOWS AN EQUAL OPPORTUNITY POLICY (1944)A

Neurochemist

Smith Kline & French Research Ltd is a member company of the SmithKline Beecham group of companies, one of the world's most innovative ethical pharmaceutical organisations with a strong commitment to research and development.

We are looking for a well motivated, experienced scientist to join our expanding Neuropharmacology Section. As a member of this group you would carry out research critical to the discovery of novel therapeutic agents for the treatment of CNS disorders. The position would be suitable for a graduate with relevant experience or someone who has recently gained a PhD in a relevant discipline. Candidates should have a background in neurochemistry, preferably with experience in HPLC or radioligand binding/autoradiographic techniques. Computer literacy, though not essential, would be an advantage.

In return, you can look forward to a competitive salary and benefits package, free BUPA and life assurance, bonus scheme, flexible working hours and subsidised sports, social and canteen facilities. Generous relocation assistance will be given where appropriate.

Please send your CV quoting reference 052/89 to the Personnel Officer, Smith Kline & French Research Ltd, The Frythe, Welwyn, Herts AL8 9AR. (1951)A

SK&F

Postdoctoral Position

Applications are invited for postdoctoral scientists to work on a Drosophila neurobiology project in the Institute for Molecular Genetics at Baylor College of Medicine, Houston, Texas. Research projects will involve studying essential genes that have been identified with P-element mediated enhancer detection and that are expressed in the peripheral nervous system of embryos or larvae. Candidates should possess a Ph.D. in Molecular Biology, Genetics, or Biochemistry. Starting date to be arranged.

Forward curriculum vitae and three letters of recommendation to: **Hugo Bellen, Baylor College of Medicine, One Baylor Plaza, Rm. T634, Houston, Texas 77030.**

We Are An Equal Opportunity Employer (NW4472)A

Postdoctoral Position Immunology

Projects to develop specific T cell immunity as cancer therapy, including characterization of autologous tumor antigens recognized by tumor infiltrating T cells, anti-clonotype antibodies as vaccines to augment specific T cell immunity, and primary *in vitro* immunization to generate tumor antigen-specific T cells.

Contact **Dr. Martin A. Cheever, Oncology, RM-17, University of Washington, 1959 NE Pacific Street, Seatle, WA 98195.** (NW4471)A

Three **POSTDOCTORAL BIOCHEMIST/CHEMIST** positions available to work with Professors Bernd Meyer and Herman van Halbeek in the study of complex carbohydrates of biomedical interest. Specific projects are (1) separation and structural analysis using LC and MS, (2) experimental conformational analysis using NMR spectroscopy, and (3) theoretical conformational analysis. Salary negotiable depending on experience. Applications received by December 1, 1989 will be reviewed then; applications received later will also be considered. Send letter of application, complete c.v., and description of research experience to **Dr. Alan Darvill, Complex Carbohydrate Research Center, The University of Georgia, 220 Riverbend Road, Athens, GA 30602, USA.** An AA/EEO institution. Post Doctoral Research at The Wistar Institute

Post doctoral positions are available at The Wistar Institute for candidates with a strong background in molecular and cell biology, virology, immunology, genetics or protein chemistry. Specific areas of research include: human retroviruses; DNA/RNA tumor viruses; growth factors; oncogenes; pattern formation in embryos; molecular mechanisms involved in the immune response; x-ray crystallography of virus receptor interaction; and aging in tissue culture. The Wistar Institute is an independent institution, located on the campus of the University of Pennsylvania and is equipped with the latest biotechnology facilities.

Starting salary at $20,000 a year. Interested applicants are requested to send a curriculum vitae and the names of 3 references to: **Coordinator of Research Training, THE WISTAR INSTITUTE, 36th and Spruce Streets, Philadelphia, PA 19104.** Equal opportunity employer, M/F. (NW4467)A

THE WISTAR INSTITUTE

STUDENTSHIPS

cf

RESEARCH STUDENTSHIPS IN BIO-MEDICAL SCIENCES

Following the discovery of the CF gene the Cystic Fibrosis Trust wishes to continue funding research on themes relating to improved diagnosis, understanding and treatment of the disease. The Trust is particularly anxious to encourage new strategies for research arising from the new knowledge of the gene and the type of protein for which it codes. It is not necessary to have access to CF patients or patient material, and applicants need not have previously worked on CF.

Maintenance awards of £4,500 will be made to research students as well as approved tuition fees. Applicants may claim research costs up to £2,000 pa.

Prospective supervisors should prepare a brief account of the proposed research (up to 1000 words) and a statement of its relevance to research on Cystic Fibrosis, which should be submitted to the Trust by 10 December 1989. Notification of successful applications will be sent together with a form asking for details of the prospective student for submission to, and approval by, the Trust before October 1990.

Initial applications should be sent to:

The Director, Cystic Fibrosis Research Trust,
Alexandra House, 5 Blyth Road,
Bromley, Kent, BR1 3RS.
Telephone: 01-464 7211.

(1952)A

THE UNIVERSITY OF MELBOURNE
Australia
CHAIR OF INORGANIC CHEMISTRY

The University of Melbourne invites applications for the Chair of Inorganic Chemistry, which has become vacant following the retirement of Professor T.A O'Donnell. The appointee shall be a distinguished inorganic chemist and be prepared to give leadership within the discipline and within the School of Chemistry.

The Department's current research programs include synthetic, spectroscopic and electrochemical studies; investigations of structures in the solid state, gas phase and using theoretical methods, inorganic rate processes and catalyst design; marine and analytical chemistry.

Salary; A$63,919 per annum. The University is currently examining the question of salary loadings and responsibility allowances.

Further information about the position, application procedure, superannuation, travel and removal expenses, housing assistance and conditions of appointment is available from the Registrar, or from Appointments (37083), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF. All correspondence (marked "Confidential"), should be addressed to the Registrar, The University of Melbourne, Parkville, Victoria, 3052, Australia, tel.(03) 344 7528, Facsimile: 344 6897.

Applications close on 24 November 1989.

The Council reserves to itself the right to make no appointment or to fill the Chair by invitation at any stage.

An equal opportunity employer (W6456)A

FELLOWSHIPS

C.H. BEST FOUNDATION POSTDOCTORAL FELLOWSHIP

In diabetes research, molecular endocrinology, molecular biology, differentiation, reproductive biology, immunology, structure and function of membranes or lipid metabolism. Tenable in the Banting and Best Department of Medical Research for two years after July 1, 1990 with a competitive stipend. Available to new Ph.D.'s or candidates with less than two years postdoctoral training by June 30, 1990 Send curriculum vitae, transcripts and three letters of reference, preferably before December 15, 1989 to. **Dr. Irving B. Fritz, Fellowship Committee Chairman, Banting and Best Department of Medical Research, University of Toronto, Toronto, Ontario, Canada M5G 1L6.**
(NW4463)A

THE ROYAL SOCIETY

EUROPEAN SCIENCE EXCHANGE PROGRAMME
POSTDOCTORAL FELLOWSHIPS

The Royal Society invites applications from UK residents for fellowships tenable in laboratories of applicants' choice in:–

Austria, Belgium, Denmark, Finland, France, Federal Republic of Germany, Greece, Republic of Ireland, Italy, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland and Turkey. Residents in these countries should apply to the Royal Society's partner organization in the country (generally the research council or academy).

Fellowships are normally for a full academic year, although applications for less than a full academic year, but not less than six months, will also be considered, as will applications for up to two years.

Preference is given to newly or recently postdoctoral applicants and the award is based on UK university lecturer rates, taking account of cost of living differences Candidates holding permanent appointments in the UK are also eligible to apply; in such instances the award will take into account any continuing salary which the candidate will receive.

The closing dates for applications in 1990 will be 12 January and 10 May, for awards to be taken up approximately 8 months after these dates.

Further details and application forms can be obtained from **The Executive Secretary (ref: ESEP/N), The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG. Telephone· 01-839 5561 (ext. 218).**

HUMAN GENOME MAPPING PROJECT
Research Assistants 1A/1B

Institute of Molecular Medicine, Oxford

Two research assistants (one senior and one junior) are required to work on the setting up and screening of YAC libraries as part of the human genome mapping initiative funded by the Medical Research Council. Initial work will involve the transfer and testing of a YAC library constructed by Olson and colleagues in St Louis, USA. The senior appointment will be made either at the top of the RS1B scale or on the RS1A scale depending on the qualifications of the applicant and with a subsequent adjustment in duties (£10,458–£15,372). The junior appointment will be made on the RS1B scale (£9,816–£14,169). The successful candidates will be responsible for setting up the YAC library and devising efficient methods of screening the colonies. This effort will be closely coordinated with active research going on in the Institute (e.g. mapping of the X chromosome and chromosome 16). The candidates will be given the opportunity to participate in the long term programme of research with the aim of constructing a full physical map of the human genome. Some molecular biology experience is essential but training will be given in the handling of yeast recombinants.

The University of Oxford is an equal opportunities employer. Applications with c.v and the names of two referees should be sent to: **Dr Kay E. Davies, Institute of Molecular Medicine, John Radcliffe Hospital, Oxford OX3 9DU.** Closing date three weeks from appearance of the advertisement. (1960)A

KRONENBOURG BREWERY

Our R&D center is located at Strasbourg (France). We are looking for a:

POSTGRADUATE OR POSTDOCTORAL RESEARCH SCIENTIST IN PLANT ENZYMOLOGY AND FERMENTATION

The job: The appointee will undertake research into the field of Brewing and Yeast fermentation process.

Appointment will be for a period of 18 months.

Send application letter with current CV and summary of research interests to:

M. ROGEAUX,
TEPRAL/KRONENBOURG, BP13CR,
67037 – STRASBOURG CEDEX – FRANCE

EMBL

EUROPEAN MOLECULAR BIOLOGY LABORATORY

PhD Programme in Molecular, Cellular, Structural and Computational Biology

The European Molecular Biology Laboratory will award predoctoral fellowships in 1990 for University graduates wishing to study for a PhD at EMBL Heidelberg, Federal Republic of Germany, or at the EMBL Outstations in Hamburg, FRG, and Grenoble, France Areas of study include· **Biocomputing** (theory and analysis of protein structure and genomic sequence information, development of computer methods for molecular biology), **Biological Structures** (structural analysis of membrane proteins and assemblies, nucleic acid-protein interactions and cytoskeletal and muscle proteins), **Cell Biology** (protein and membrane traffic, membrane biogenesis, post-translational modifications, functional aspects of the nucleo- and cytoskeleton), **Differentiation** (oncogenes, growth factors and growth control, haemopoietic cell differentiation, developmental and tissue-specific gene expression), **Gene Expression** (regulation of gene expression at the transcriptional and post-transcriptional level, protein engineering, structure and function of small RNAs) and **Instrumentation** (technical innovations relevant to molecular, cellular and structural biology). At the **Outstations,** biological structures and dynamics are studied using the specialised techniques of synchrotron radiation (Hamburg) and neutron diffraction (Grenoble).

To be eligible, candidates must hold, or anticipate receiving in 1990, a first or upper second class honours degree, a masters degree, a diploma or equivalent in biological sciences, physical sciences or mathematics.

Candidates must be citizens of the member states of EMBL or EMBC namely Austria, Belgium, Denmark, Finland, France, Federal Republic of Germany, Greece, Iceland, Ireland, Israel, Italy, Netherlands, Norway, Spain, Sweden, Switzerland or the United Kingdom.

The deadline for receipt of completed applications is December 31, 1989. Successful candidates will be notified by the end of March 1990 Those awarded predoctoral fellowships will be expected to begin working at EMBL in 1990 The normal duration of the fellowships will be 3½ years

Application forms and a brochure giving further information about the research at EMBL and the groups participating in the Laboratory's PhD programme are available on request from· **Dean of Graduate Studies, EMBL, Postfach 10.2209, D-6900 Heidelberg, Federal Republic of Germany.**

(W6530)E

POSTDOCTORAL RESEARCH TRAINING FELLOWSHIPS

available immediately in the areas of: (i) The neuro-virology and -immunology, -endocrinology, -pathology, -psychiatry, and -psychology of *HIV* and *AIDS*; ii) The epidemiology of CNS *HIV* infection and *AIDS*; iii) The role of psychosocial and emotional co-factors in the natural history of *HIV* infection; iv) The passage of anti-viral drugs through the blood-brain barrier. Eligibility U.S. citizens or permanent residents. M.D , D.O and completion of accred. residency, Ph.D. or equivalent. NIMH stipend plus supplement. Send curriculum vitae, three letters of reference, research proposal in area of interest to: **Dr. Herbert Weiner, C8-861, Neuropsychiatric Institute, UCLA, 760 Westwood Plaza, Los Angeles, Ca. 90024-1759.** UCLA is an EO/AAE.

(NW4431)E

WEIZMANN INSTITUTE OF SCIENCE
Rehovot 76100 Israel

POSTDOCTORAL FELLOWSHIPS

The Feinberg Graduate School of the Weizmann Institute of Science is now offering Postdoctoral Fellowships in the following fields of study:

Life sciences **Physics**
Chemistry **Mathematics**
Science teaching

These Fellowships are intended for young scientists who have recently received a Ph.D. degree.

The fellowship provides a 12-month stipend (with COL adjustments), a relocation allowance and airfare to Israel. If the Fellowship is renewed for a second year, return airfare is provided.

Application forms and additional information may be obtained from:

The Feinberg Graduate School
The Weizmann Institute of Science
Rehovot 76100, Israel

Applications are reviewed twice each year: January 1 and May 15

(W6457)E

UNIVERSITIES OF GLASGOW AND STRATHCLYDE
WELLCOME BIO-MAGNETISM UNIT

RESEARCH FELLOW in Clinical Neurophysiology

Applications are invited for a post-doctoral Research Fellow in this newly constructed Unit at the Institute of Neurological Sciences, Glasgow The appointee will take part in a research programme funded by the Wellcome Trust comparing electrophysiological and magneto-physiological methods of recording normal and abnormal nervous system function. Previous interest in visual and/or spinal cord physiology would be an advantage as well as experience in human evoked potential recordings.

The salary would be on the 1A range of salary scales for Research and analogous staff commencing at the 4th point (£12,150-£13,870) Clinically qualified applicants may be considered for Honorary NHS grading appropriate to their experience, plus an adjustment to a clinical salary scale The post is available immediately and is funded for a maximum of four years, reviewable biannually

Applications with names of 2 referees should be made to **Dr Andrew I Weir, Consultant Clinical Neurophysiologist, Department of Clinical Neurophysiology, Institute of Neurological Sciences, Southern General Hospital, Glasgow.**

Closing date for applications: 28 November 1989

(1930)E

Post Doctoral Research Fellow

Computer Modelling of Protein Structure

The Imperial Cancer Research Fund is the largest independent cancer research institute in Britain, with wide ranging interests in fundamental, applied and clinical research

Applications are invited for a three year postdoctoral research fellow to work on the development of methods to model and predict protein structure from sequence using computer graphics and databases. The methods will be applied to study the structure and function of proteins relevant to cancer

£14,800-£18,400

For further details contact Dr Mike Sternberg, Biomolecular Modelling Laboratory, on 01-269 3565 Applications, including a curriculum vitae and details of three referees, should be sent to the Recruitment Officer, Imperial Cancer Research Fund, 44 Lincoln's Inn Fields, London WC2A 3PX.

Smoking is actively discouraged.

MAF

MAFTECH FELLOWSHIPS "FACIAL ECZEMA" RESEARCH BIOCHEMIST/ORGANIC CHEMIST/ MOLECULAR BIOLOGIST/MYCOLOGIST

MYCOTOXIC DISEASES GROUP, RUAKURA AGRICULTURAL CENTRE
MAF, PRIVATE BAG, HAMILTON, NEW ZEALAND
VACANCY NO. MTN 89/63

Applications are invited for Post-Doctoral Fellowships to collaborate in Mycotoxic Diseases Group research programmes with one of the following goals:

(1) A ruminal organism modified to detoxify sporidesmin

(2) A marker protein or DNA probe for facial eczema resistance

(3) A strain of Pithomyces chartarum modified to be a non-toxin producer capable of dominating and supplanting the wild type

Facial eczema is a hepatogenous mycotoxicosis, involving secondary photosensitisation of exposed areas of skin in grazing livestock in New Zealand. The mycotoxicosis is caused by a toxin, sporidesmin, produced by the saprophytic fungus, Pithomyces chartarum. Sporidesmin has been isolated, purified and its structure determined. The histology and pathology of the disease is well characterised and the biochemical mode of action of the toxin largely determined. A heritable resistance to the toxin has been identified and breeding programmes designed to increase livestock resistance to the disease implemented. Despite progress made, facial eczema is still a major animal health problem and novel approaches are required to provide long-term control methods.

Fellows would join one of the following programmes:

A Modification of ruminal micro-organisms to promote sporidesmin metabolism and detoxification.
Biochemist/Molecular Biologist with interests in microbiology is required to initiate a programme which will screen anaerobic organisms for ability to metabolise sporidesmin with the ultimate aim of introducing this activity into rumen-adapted micro-organisms. Experience in enzyme purification and gene identification is desirable.

B The study of the pathways pharmacokinetics of sporidesmin metabolism and excretion in facial eczema resistant and susceptible sheep.
Biochemist/Organic Chemist with interest in intermediary metabolism. Applicant would be expected to provide the analytical support for a programme elucidating changes in the metabolism and excretion of sporidesmin that are responsible for the differences in resistance to the toxin. Experience in relevant analytical techniques eg. HPLC, GC, FTIR and GC-mass spectrometry desired.

C A study of the factors promoting production of sporidesmin by Pithomyces chartarum.
Mycologist/Biochemist to investigate the advantages conferred by toxin production. Although most New Zealand isolates produce sporidesmin some isolates reported from South Africa and the USA do not. An understanding of why this is so would be an important step in a programme investigating the possible production of a non-toxic strain of Pithomyces to supplant the wild type.

Fellow would be appointed for an initial 2-3 year period with possible re-appointment of Fellows making a major contribution to promising programmes. Salary would depend on previous experience but would normally be in the range $NZ32,257 to $37,748. Travel expenses will be covered under the Fellowship.

Further information can be obtained from Dr Neale Towers, Ruakura Agricultural Centre, Private Bag, Hamilton, New Zealand. Telephone 64-71-62839; FAX 64-71-385658.

Applications quoting vacancy number MTN 89/63 including a curriculum vitae and the names of two referees should be sent to:

Management Support Officer
Animal Research Group
MAFTech
Ruakura Agricultural Centre
Private Bag
Hamilton

Applications for vacancy close on 30 November 1989. (W6638)E

The Wellcome Trust

Training Fellowships in Health Services Research

The Trustees invite nominations for Training Fellowships in Health Services Research These awards, which are tenable for up to three years, are intended for the support of younger medical or non-medical graduates with some appropriate experience who wish to pursue a career in Health Services Research.

Health Services Research is broadly defined as the identification and quantification of health care needs and the quantitative study of the provision and use of health services. The research is usually multi-disciplinary and involves clinical, epidemiological, social science, economics, operational and management disciplines. It is concerned with populations, and with both the cost and effectiveness of health care interventions

Further particulars and an application form may be obtained from: The Grants Section (HSR/SC), The Wellcome Trust, 1 Park Square West, London NW1 4LJ. Tel: 01-486 4902 ext 273.

The closing date for receipt of applications is 5th January 1990. Late applications will not be accepted.

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited from candidates with PhDs in Pharmacology or a related discipline for an ICI Pharmaceuticals Limited funded Postdoctoral Research fellowship (tenable for 2 years) to study ionic currents in cardiac myocytes. Preference will be given to candidates with backgrounds in electrophysiology or the cardiovascular system. Salary in range:- £10,458-£15,372 per annum.

Applications (Ref· R80/89) with full CV and the names and addresses of 2 referees should be sent by 10th November 1989, to **Dr K A Kane, Department of Physiology and Pharmacology, University of Strathclyde, Glasgow G1 1XW,** who will be pleased to supply further information. (1922)E

UNIVERSITY OF DURHAM RESEARCH FOUNDATION

ADDISON WHEELER FELLOWSHIP

Applications are invited for an Addison Wheeler Fellowship tenable for five years from as soon as possible. The Fellowships were established to encourage "efforts for increased knowledge of Man and his physical make-up so as to enable him to make better use of his life here on earth". It is assumed that candidates will be working in the Life Sciences, but candidates in other fields who feel that their research meets the aims of the Wheeler Fellowships are encouraged to apply.

Candidates must be under 28 years of age on taking up the Fellowship. Salary on Research Grade 1A, currently £10,458-£16,665 per annum.

Applications (three copies) including details of the proposed field of study and naming three referees, should be sent by 31 October 1989 to the **Deputy Secretary, Old Shire Hall, Durham DH1 3HP** from whom further particulars may be obtained

(1934)E

STUDENTSHIPS

THE ROYAL SOCIETY

JOHN MURRAY TRAVELLING STUDENTSHIP IN OCEANOGRAPHY AND LIMNOLOGY 1990

Applications are invited for the above Studentship, open to British graduates under the age of 35, for the encouragement of travel and work in oceanography or limnology. This award, which may be held for periods from three months to one year, will in 1990 be up to £2500, adjusted according to qualifications and place and duration of research. Applications are especially invited from workers in oceanography and limnology, as well as in zoology, botany, geology, mathematics and physics, and it will be permitted to hold the award while receiving a salary from a regular appointment.

Applications receivable by 15 December 1989 should be made on forms obtainable from **Mrs U. M. A. Tokle, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG.** (1927)F

ST. HILDA'S COLLEGE, OXFORD OX4 1DY

Junior Research Fellowship

The College invites applications from women graduates for the EPA-Brereton-Sherman Junior Research Fellowship from 1st October 1990, for two years renewable for a third, for studies in Chemistry, Medicine or the Biological Sciences.

Further particulars should be obtained from the **College Secretary** to whom completed applications (8) should be returned by 8th January 1990. (1929)E

MRC Human Genetics Unit, EDINBURGH

MRC PhD Studentship

A studentship funded by the Human Genome Mapping Programme is available now to investigate the use of embryonal stem cells for rapidly making and mapping mutations in the mouse. The studentship will be held in the Molecular Genetics Section of this large, well-equipped and very active institute, under the supervision of Dr Ian Jackson.

Applicants having an appropriate 1st or upper 2nd class degree, and satisfying MRC residency requirements should telephone Dr. Jackson on 031 332 2471 xt 3301 or write as soon as possible to **MRC Human Genetics Unit, Western General Hospital, Crewe Rd., Edinburgh EH4 2XU.** (1942)F

Post-Doctoral Fellowships

The Imperial Cancer Research Fund is one of the largest independent cancer research institutes in Europe employing approximately 400 scientists and clinicians. It has a wide-ranging programme in fundamental, applied and clinical cancer research.

There are approximately seventy research groups encompassing the major disciplines of cellular and molecular biology including biochemistry, genetics, immunology, and virology. Most are housed at the main building in Central London: there are also research units at Clare Hall, North London and at Dominion House attached to St. Bartholomew's Hospital. ICRF's external clinical units based in major teaching hospitals form the link between fundamental research and clinical activities.

Each research group works independently. All have access to centralized services including cell production, oligonucleotide and peptide synthesis, amino acid and DNA sequencing, a library of DNA probes and somatic cell hybrids for gene mapping, experimental animal breeding and maintenance including transgenic mice, electron microscopy, and a large computer facility.

Fellowships

Approximately 40 post-doctoral fellowships are available each year to scientists of any nationality Most of these are three-year fellowships, but visiting fellowships for a period of one or two years are also offered.

Salaries for post-doctoral fellows are in the range of £12,500-£16,000, dependent on age and experience. This is subject to UK tax but avoidance of double taxation agreements exist with all countries of the EEC, the Commonwealth and the USA. Salaries for Visiting Fellows are dependent on age and experience. Visitors are entitled to medical and dental care under the National Health Service. ICRF will provide assistance with relocation expenses.

The projects currently available are listed below.

1 **John Armstrong:** Role of ras-like G-proteins in membrane traffic of S pombe.

2 **David Bentley** Regulation of transcription in differentiation

3 **Lionel Crawford**· Transformation of human keratinocytes by human papillomaviruses and oncogenes.

4 **Andrew Creighton**· Targeting ^{32}P-labelled monoclonal antibodies to tumour tissue.

5 **Julian Downward**· Studies of a novel protein that controls the activation state of ras oncogene products.

6 **Gerard Evan** Identification and analysis of genes involved in the promotion and regulation of mammalian cell growth

7 **Paul Freemont.** X-ray crystallographic studies of two myeloid calcium binding proteins, P8/P14.

8 **Michael Fried:** Molecular analysis and cloning of amplified DNA

9 **Michael Fried**· Mammalian gene organisation and expression.

10 **Anna-Maria Frischauf:** Finding candidate genes for polycystic kidney disease

11 **Sandra Gendler** Analysis of molecular events in breast cancer

12 **Peter Goodfellow:** Molecular analysis of sex determination in man.

13 **Peter Goodfellow**· Development of methods for human genome analysis.

14 **Ian Hart:** Molecular mechanisms in regulation of melanoma development.

15 **Bridget Hill:** Differential repair and tolerance of cisplatin-induced DNA damage in human tumour cells

16 **Michael Horton**· Molecular analysis of bone cell specific genes

17 **Peter Karran**· Control of the expression of the human DNA repair enzyme O^6-methylguanine-DNA methyltransferase

18 **Ian Kerr.** The control of interferon-inducible gene expression and the mechanism of action of the interferons

19 **Roger King:** Hormone sensitivity of normal and neoplastic human epithelium.

20 **Hartmut Land:** Isolation and functional analysis of cellular genes able to co-operate with ras

21 **Hans Lehrach** Molecular approaches to subdivide human chromosomes X and 21

22 **Tomas Lindahl:** Deficiencies and inducibilities of DNA Glycosylases.

23 **Mark Meuth**· Fine structure deletion mapping of a putative origin of DNA replication in the hamster APRT locus

24 **Mike Owen**· Tissue specific gene expression and cell surface interactions during thymocyte development

25 **Malcolm Parker:** Molecular aspects of steroid hormone action

26 **Gordon Peters**· Analysis of genes on chromosome 11q13 in relation to breast cancer.

27 **Ellen Solomon.** Molecular genetic analysis of sporadic colorectal carcinoma

28 **Michael Sternberg:** Prediction of protein structure using computer graphics.

29 **Joyce Taylor.** The receptor for HuIFN-α2 Binding studies and gene cloning

30 **Joyce Taylor:** Oncogenic transformation of human mammary epithelial cells.

31 **Philip Thorpe**· Immunotoxins for the selective destruction of tumour vasculature

32 **John Trowsdale** Mammalian zinc finger genes and regulation of differentiation

33 **Sue Watt/Bryan Young.** Identification of regulatory elements for the CD7 gene

34 **Stephen West** The molecular biology of genetic exchange

35 **Roland Wolf** Molecular genetic analysis of the mammalian cytochrome p-450 system

36 **Bryan Young** Flow sorting and analysis of human chromosomes

Applications for 1990 will be considered at the February and June meetings of the Academic Board Further project details can be obtained from the address below. Completed applications should be submitted two months prior to the Academic Board meetings.

ARE YOU LOOKING FOR OPPORTUNITY IN RESEARCH?

Research Development Corporation of Japan (JRDC), established in 1961, is a government owned organization which operates under the Science and Technology Agency (STA).

The objective of JRDC is to effectively carry out the development of new technology, engage in the basic research deemed to contribute to the creation of new technology, and to disseminate the outcome of these developments and basic research.

In addition to these activities, JRDC is to undertake the promotion of the International Research Exchange Program, consisting of 1) The International Joint Research Program, 2) The STA Fellowship Program, 3) The Support Programs, and 4) The Research Information Program.

INTERNATIONAL JOINT RESEARCH PROGRAM

1. Purpose

This program shall work toward the following purposes through joint research supported by JRDC and foreign research organizations:

(1) Develop the seeds of innovative science and technology by integrating the advanced research activities of Japan and of other countries concerned; (2) Contribute internationally by fostering broad public dissemination of the knowledge gained from such research; and (3) Promote research exchange between Japan and other countries, thereby promoting science and technology.

2. Outline of the Program

Non-Japanese research organizations wishing to conduct joint research projects with JRDC shall carry out such research with JRDC within the following framework, and shall share, on an equitable basis, personnel and all expenses and costs necessary for the implementation of the research.

(1) Research fields and themes

Research themes are to be sought in basic research fields including new materials, life sciences and electronics. Themes should be directed toward creating new concepts that will become the seeds of innovative science and technology development. These research themes must be those for which consent is obtained from both JRDC and its counterpart.

(2) Framework for a Joint Research Project (Standard model for joint research)

① Term: 5 years (Flexible: 3 to 7 years)

② Budget: ¥ 2 to ¥ 3 billion (approx U.S.$14–21 mil.) [Each side bears ¥ 1 to 1.5 billion]

③ Site:

A research site shall be established at a suitable university or a research institute.

④ Researchers:

Both JRDC and its foreign counterpart concerned may select their respective researchers from academia, industry and government.

i) Research directors: 2 (one from each side)

ii) Researchers: 15 to 20 in total for both countries.

⑤ Patent rights:

The patent rights resulting from the joint research should be jointly owned on an equitable basis.

STA FELLOWSHIP PROGRAM

1. Purpose

The purpose of this program is to promote the international exchange of researchers by providing fellowships to foreign researchers in the science and technology fields (excluding those concerned exclusively with the humanities).

2. Outline of the Program

Fellowship awardees fall into two categories: (1) those recommended by their own governments and (2) those recommended by Japanese host institutes.

(1) Numbers of awardees: 130 for FY 1989 (100 for FY 1988).

(2) Qualifications:

① Possession of a doctoral degree in a scientific or engineering field, or an equivalent qualification.

② Age under 35, in principle.

③ Having sufficient language ability to be able to pursue research in Japan. Japanese ability is preferable, but in most cases English ability is sufficient. With the host institute's agreement, other languages may also suffice.

3. Tenure and field of research:

Tenure is between 6 months and 2 years, to be decided through negotiation between the candidate and the host institute.

The field of research is also decided through negotiation between the candidate and the host institute. The results of research work produced during the tenure will be subject to the regulations of the host institute.

4. Fellowship awards:

The following items will be provided to the Fellowship awardees as tax-free allowances.

① Round-trip airline ticket (economy class).

② Living allowance: ¥ 270,000 per month, (approx U.S.$2,000).

③ Family allowance: ¥ 50,000 per month (approx U.S.$370).

④ Housing: ¥ 100,000 maximum per month (approx. U.S.$740) may be paid as housing allowance; any shortfall is to be borne by the awardee.

⑤ Relocation allowance for moving from overseas to Japan: ¥ 200,000 (approx. U.S.$1,500).

⑥ Travel allowance (in Japan for business trips regarding research activities): ¥ 100,000 maximum per year (approx. U.S.$740).

5. Host Institutes

Host institutes comprise national laboratories (excluding universities and laboratories affiliated with universities), public (semi-government) corporations, and non-profit organizations.

JRDC is to undertake the implementation of STA Fellowship Program: Japan International Science and Technology Exchange center (JISTEC) is responsible from the receipt of the application from candidates and liaising with them.

SUPPORT PROGRAMS

In order to help foreign researchers, who are engaging in research or exchanging information at Japanese research institutes, and their families to make a smooth transition to research and enjoy their everyday life, JRDC is to promote support programs such as assistance to find houses, supply of information on living in Japan, counselling for daily life and Japanese language lessons.

RESEARCH INFORMATION PROGRAM

For foreign research institutes and researchers who are seeking opportunities for research exchange with Japanese counterparts, information focused on Japanese research activities will be provided.

GRANTS & SCHOLARSHIPS

Stipendienprogramm zur Verstärkung der AIDS-Forschung in der Bundesrepublik Deutschland

Auf Empfehlung der wissenschaftlichen Gemeinschaft und durch einen Senatsbeschluß der Deutschen Forschungsgemeinschaft inhaltlich mitgetragen, vergibt das Deutsche Krebsforschungszentrum aus Mitteln des Bundesministeriums für Forschung und Technologie im Interesse einer Verstärkung der Forschung zur erworbenen Immunschwäche AIDS

Stipendien für

Molekularbiologie, Virologie, Immunologie und Epidemiologie

an promovierte Mediziner und Naturwissenschaftler.

Umfang und Laufzeit

Jährlich können bis zu 50 Stipendien für eine Gesamtlaufzeit von 5 Jahren vergeben werden. Davon sind zwei Jahre Auslandsaufenthalt an einer international ausgewiesenen Forschungseinrichtung vorgesehen. Anschließend soll das Forschungsprogramm drei Jahre an einer deutschen Institution, nach Wahl des Stipendiaten, fortgeführt werden. Anstelle des Stipendiums kann auch eine Beschäftigung im Angestelltenverhältnis (BAT Ib) treten.

Voraussetzungen

- Die Bewerber sollten zum Zeitpunkt der Antragstellung nicht älter als 35 Jahre sein.
- Die Förderung setzt voraus, daß die Antragsteller nach oder während der Promotion herausragende wissenschaftliche Leistungen erbracht haben. Die Promotion soll nicht länger als 5 Jahre zurückliegen.
- Die Bewerber müssen ihren ständigen Wohnsitz in der Bundesrepublik Deutschland oder in Berlin(West) haben.

Der Bewerbung sind sowohl detaillierte Angaben zu den im Ausland angestrebten Forschungsarbeiten auf der Grundlage der bisherigen wissenschaftlichen Tätigkeit als auch die Stellungnahme eines in der Forschung und/oder der Lehre tätigen Wissenschaftlers zur Person und zum wissenschaftlichen Vorhaben des Antragstellers beizufügen.

Interessenten können für die Antragstellung beim Deutschen Krebsforschungszentrum ein Merkblatt einschl. eines Bewerbungsformulars anfordern. Bewerbungen sind bis **31. Dezember 1989** an

Deutsches Krebsforschungszentrum
AIDS-Stipendienprogramm
im Neuenheimer Feld 280
D-6900 Heidelberg

zu richten.

THE ROYAL SOCIETY
MARINE SCIENCES RESEARCH GRANTS 1990

The Council of the Royal Society invotes applications from qualified research workers of Ph.D. or equivalent status for personal grants from three funds for marine sciences:

(a) *Browne Research Fund:* for research in marine biology at a marine biological laboratory or elsewhere. Preference will be given to those who propose to work on purely scientific problems rather than to those whose work would be primarily directed towards an economic end.

(b) *Maurice Hill Research Fund:* established in memory of the late Dr M.N. Hill, F.R.S., for research in the general fields of physical and chemical oceanography, marine geophysics and geology, either at sea or in laboratories and institutes having adequate facilities.

(c) *Marshall and Orr Bequest:* for the support of marine biological research.

Grants may be used for periods up to one year, and are made on the understanding that university or other posts held by applicants will meanwhile be kept open for them. Recipients are permitted to use grants while receiving salaries from regular appointments.

In 1990 the total amounts available to be shared among all successful applicants will be about £8,000 from the Browne Research Fund, £19,000 from the Maurice Hill Research Fund and £24,800 from the Marshall and Orr Bequest; individual grants will not ordinarily be more than £2,500.

Applications should be made on forms to be obtained from **Mrs U.M.A. Tokle, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG,** and returned by 15 December 1989. (1928)H

ST. HUGH'S COLLEGE
OXFORD
GRADUATE SCHOLARSHIPS

St. Hugh's offers a range of scholarships for graduates for October 1990, each of £1,250 p.a., for a period normally depending on the fee-paying duration of the student's course. Scholarships are offered in both arts and sciences.

Each graduate scholar will be entitled to a room in St. Hugh's graduate accommodation for two years at the standard charge, and to dine periodically at the High Table.

Awards to applicants not already reading for a higher degree at Oxford will be conditional on their being accepted to do so by the relevant Faculty Board of the University

Further particulars of the Scholarship and of the application procedure may be obtained from the **Tutor for Graduates, St. Hugh's College, Oxford 0X2 6LE,** who should receive applications by Thursday, *1st March 1990.* (1907)H

COURSES & CONFERENCES

COURSES ON
PROTEIN AND DNA ELECTROPHORESIS TECHNIQUES

Organised by Harish Patel and Alan D.B. Malcolm
Department of Biochemistry,
Charing Cross and Westminster Medical School,
Fulham Palace Road, London W6 8RF.

Both courses consist of lectures and hands on practice. Various aspects of electrophoresis techniques and applications will be discussed including the following topics:

Protein course 9 & 10 Jan. '90	1	Immunoelectrophoresis
	2	Isoelectric focusing
	3	Two Dimensional electrophoresis
	4	Protein Blotting Techniques
	5	Densitometry
DNA course 11 & 12 Jan '90	1	Nucleic Acid Blotting
	2	Nucleic Acid Hybridisation
	3	DNA Sequencing
	4	Pulsed Field Gel Electrophoresis
	5	PCA
	6	Gel analysis and trouble shooting of DNA sequencing

For further details write to Shirley Line at the above address (Tel 01-846 7048). (1955)C

COLD SPRING HARBOR LABORATORY

PROTEIN PURIFICATION AND CHARACTERIZATION
April 16 - 30, 1990

Daniel R. Marshak, *Cold Spring Harbor Laboratory*
Bruce W. Erickson, *University of North Carolina*
Jim Kadonaga, *University of California, San Diego*
John A. Smith, *Harvard Medical School*

This course is intended for scientists who are not familiar with techniques of protein isolation and characterization. Students will learn the major techniques in protein purification by actually performing four separate isolations including: (i) a regulatory protein from muscle tissue; (ii) a fusion protein from *E. coli;* (iii) a DNA binding protein from nuclei of tissue culture cells; and (iv) a chemically synthesized peptide. A variety of chromatographic, electrophoretic, and bulk fractionation techniques will be employed including: ion exchange, gel filtration, hydrophobic interaction, affinity-based adsorption, and immunoaffinity chromatography; polyacrylamide gel and two-dimensional gel electrophoresis and electroblotting; precipitation by salt and pH; and HPLC analysis. Methods of protein characterization will be discussed including amino acid analysis, protein sequencing, and mass spectrometry. Emphasis will be placed on methods of protein purification rather than automated instrumental analysis. Guest lecturers will discuss protein structure, modifications of proteins, and methodologies for protein purification. Applications of protein biochemistry to various areas of research in molecular biology will be discussed. Guest lecturers include: R. Aebersold, B. Dunbar, D. Graves, L. Gierasch, Y. Paterson, P. Robbins, G. Rose, and K. Wilson

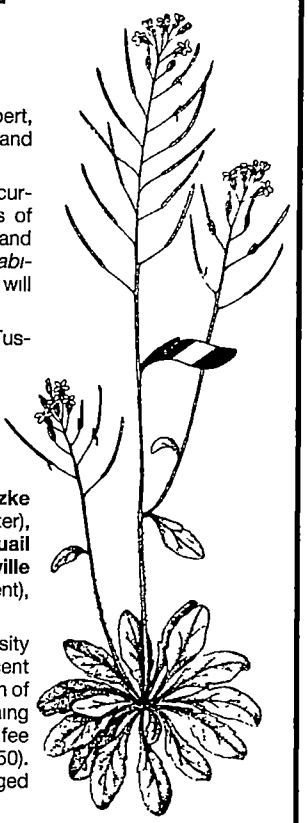
CLONING & ANALYSIS OF LARGE DNA MOLECULES
April 17 - 30, 1990

Robert Gemmill, *Eleanor Roosevelt Institute, Denver*
Nat Sternberg, *E. I. DuPont de Nemours & Co.*
Sue Klapholz, *Stanford University*

This course will cover the theory and practice of manipulating and cloning high molecular weight DNA. Lectures and laboratory work will deal with the use of bacteriophage P1 and yeast artificial chromosome (YAC) cloning systems, the isolation and manipulation of high molecular weight DNA from mammalian cells for cloning (including the size-selection of 200-300 kb DNA fragments), and the analysis of high molecular weight DNA by pulse field gel (PFG) separation techniques. P1 and YAC recombinant DNA molecules will be produced, introduced into cells (*E. coli* and yeast, respectively), and reisolated after appropriate clone selection and colony screening procedures. Comparison of DNA separation capabilities will be made among the five major PFG techniques commonly in use. All aspects of Southern blot analysis of DNA will be covered including sample digestion with restriction enzymes, separation on pulse field gels, Southern transfer, hybridization, and interpretation of results. Students will gain hands on experience through participation in ongoing efforts to prepare physical maps of portions of human chromosomes 3 and 12. Lectures by outside speakers on topics of current interest will supplement the laboratory work.

Tuition, room and board.....$1,390

Application deadline: January 15, 1990



Application/information may be obtained from:

REGISTRAR
Cold Spring Harbor Laboratory
Cold Spring Harbor, New York 11724
Phone: 516-367-8343

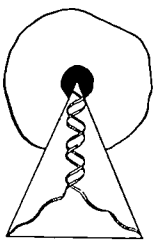
FOURTH INTERNATIONAL CONFERENCE ON *ARABIDOPSIS* RESEARCH

Vienna, June 2–5, 1990

organized by D. Schweizer, R. Albert, E. Heberle–Bors, W Löffelhardt and M. Maluszynski.

The Conference is to cover all aspects of current *Arabidopsis* research Contributions of general interest dealing with the genetics and molecular biology of plants other than *Arabidopsis* will also be considered Speakers will include:

F.M. Ausubel (Boston), **H.J. Bohnert** (Tuscon), **A.R. Cashmore** (Philadelphia), **N.H. Chua** (New York), **K.A. Feldmann** (Wilmington), **G.R. Fink** (Cambridge/USA), **R.B. Flavell** (Norwich), **R.B. Goldberg** (Los Angeles), **H.M. Goodman** (Boston), **W. Gruissem** (Berkeley), **M. Koornneef** (Wageningen), **A.J.M. Matzke** (Salzburg), **D.W. Meinke** (Stillwater), **E.M. Meyerowitz** (Pasadena), **P.H. Quail** (Albany), **J. Schell** (Koln), **C.R. Somerville** (East Lansing), **M. Van Montagu** (Gent), **L. Willmitzer** (Berlin).



The Conference will be held in the University of Vienna–Biocenter and in the adjacent WU-buildings and will start in the afternoon of Saturday, June 2nd, and finish in the evening of Tuesday, June 5th, 1990. The Congress fee will amount to OS 2000, -- (approx. $150). Only half of the Congress fee will be charged from bona fide Ph.D students

Fundación Juan March

International Meetings on Biology
Approaches to Plant Development
12-15 February, 1990. Madrid Spain

Lecture Course: review of cellular, genetic and molecular data related to Plant Development **Topics will include:** Genetic analysis of developmental mutants, transposon tagging, use of chimeric plants and clonal analysis, somatic embryogenesis, control of development by hormones and agrobacterium, advanced cell and molecular techniques applied to model plant systems, molecular mechanisms of gene control Examples of animal systems will also be reviewed. **Speakers:** M Delseney, S de Vries, M Estelle, M Freeling, P Hoykaas, J.M Martínez, J Modolell, T Nelson, M Pagès, S. Poethig, P Puigdoménech, J Rothman, F Salamini, A Spena, I Sussex **Organizers:** Dr Pedro Puigdoménech, CSIC Barcelona Spain, Dr Timothy Nelson, Yale University New Haven, USA **Participants:** Attendance limited to 25 Applications should include a short curriculum vitae, a statement on current research, and intention of presenting a poster Send to. **Dr. Pedro Puigdomênech. Departamento de Genêtica Molecular. CID-CSIC. Jordi Girona, 18. 08034 Barcelona. Spain. Fax: 34-3-2045904.**

Deadline: November 25th
No application fee is required A limited number of fellowships are available to help cover travel and accomodation expenses Desire to apply should be expressed in letter of application.

the widest international selection of jobs in science — EVERY WEEK

International Medical Course

Oncogenes and human cancer

3–8 June 1990, London

This course is being organized by the British Council in co-operation with the Department of Clinical Oncology and the ICRF Oncology Group, Royal Postgraduate Medical School, Hammersmith Hospital. The aim is to review the remarkable recent advances in the application of molecular biology to our understanding of cancer.

The following topics will be discussed: growth factors; growth factor receptors; cytoplastic oncoproteins as second messengers; nuclear oncoproteins and transcription factors; and tumour suppressor genes.

The Co-Directors of Studies will be **Dr William Gullick,** ICRF Oncology Group and **Professor Karol Sikora,** Department of Clinical Oncology, Royal Postgraduate Medical School, Hammersmith Hospital London.

The course is designed for those with some experience in laboratory work and who wish to review the impact of molecular biology on cancer research.

There are vacancies for 40 participants.

Course fee: £565; accommodation charge: £285; total fee: £850.

The course will be held at the Wolfson Conference Centre, Royal Postgraduate Medical School, London. Resident participants will be accommodated in a centrally placed and convenient hotel.

The British Council

Further information and application forms are available from British Council Representatives overseas or from Courses Department, The British Council, 65 Davies Street, London, W1Y 2AA.

CALL FOR
POSTERS AND SHORT REPORTS

"Advances in Gene Technology: The Molecular Basis of Immune Diseases"

January 21-26, 1990

The major gene technology conference of 1990 - **THE MIAMI BIO/TECHNOLOGY WINTER SYMPOSIA** is announcing its call for poster presentations that will appear in the conference proceedings as Short Reports and will be published by the ICSU Press and IRL Press.

Poster sessions are scheduled for January 22,23, and 24, 1990 at which time you may present your reports on 4' high x 6' wide corkboards provided for the occasion. The Short Report is the permanent record of your poster.

To have your Short Report considered for acceptance, you must be registered for the Symposia, and your Short Report must be received no later than **November 1, 1989.** Notification of acceptance will be sent within three weeks of the closing deadline.

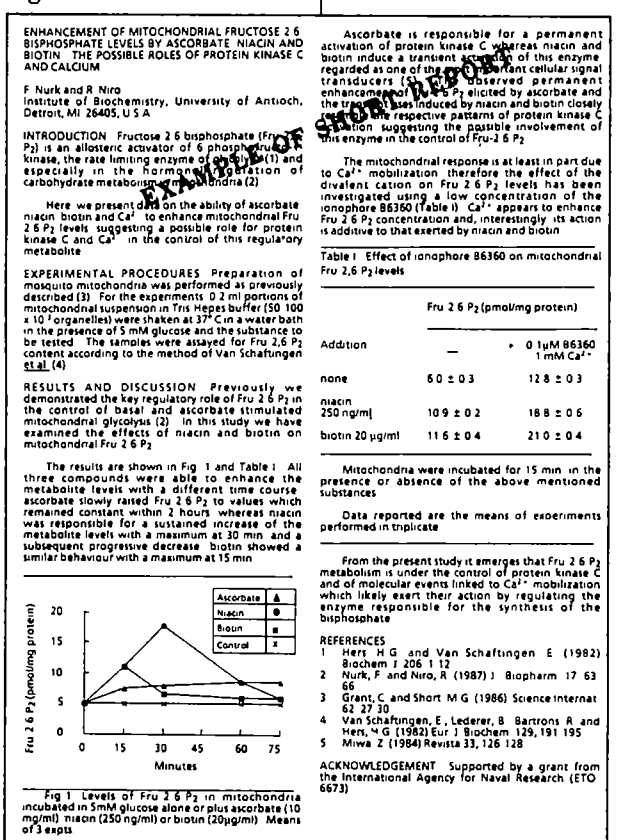
GUIDELINES FOR PREPARING SHORT REPORTS

To give your report the best chance of being accepted by the Symposia, try to follow these simple guidelines:

Legibility. The type style must be letter quality. Neatness counts.

Technical Specifications. Use the grid paper or type on two A4 or legal size sheets within a grid of 10 cm. wide and 28 cm. deep. Do not draw lines around your Report. Type size - 12 pitch. Single space. Number the pages in pencil on the reverse.

Length of Report. Two columns (2 grids of 10 x 28 cm) equals one page. **You must occupy two (2) columns in order to be considered for publication.** Anything under or over will automatically be rejected.



Headings. Capitalize headings for major sections either by topic, or organizationally, e.g. INTRODUCTION, DISCUSSION, REFERENCES.

Subheadings. Use capitals for initials and underline the phrase.

References. Cite these by number in the order in which they appear in the text. Collect the bibliography into a section at the end. **A bibliography is essential.**

Acknowledgements. These should appear last.

Make certain your work is represented at this important event. **Mail** your **UNFOLDED** Short Report to: MIAMI BIO/TECHNOLOGY WINTER SYMPOSIA, P O. Box 016129, Miami, FL 33101, USA. ENHANCEMENT OF MITOCHONDRIAL FRUCTOSE 2 6 BISPHOSPHATE LEVELS BY ASCORBATE NIACIN AND BIOTIN THE POSSIBLE ROLES OF PROTEIN KINASE C AND CALCIUM

F Nurk and R Niro
Institute of Biochemistry, University of Antioch, Detroit, MI 26405, U S A

INTRODUCTION Fructose 2 6 bisphosphate (Fru 2 6 P_2) is an allosteric activator of 6 phosphofructo 1 kinase, the rate limiting enzyme of glycolysis (1) and especially in the harmonious regulation of carbohydrate metabolism in mitochondria (2)

Here we present data on the ability of ascorbate niacin biotin and Ca^{++} to enhance mitochondrial Fru 2 6 P_2 levels suggesting a possible role for protein kinase C and Ca^{++} in the control of this regulatory metabolite

EXPERIMENTAL PROCEDURES Preparation of mosquito mitochondria was performed as previously described (3) For the experiments 0 2 ml portions of mitochondrial suspension in Tris Hepes buffer (50 100 x 10^{-3} organelles) were shaken at 37° C in a water bath in the presence of 5 mM glucose and the substance to be tested The samples were assayed for Fru 2,6 P_2 content according to the method of Van Schaftingen et al (4)

RESULTS AND DISCUSSION Previously we demonstrated the key regulatory role of Fru 2 6 P_2 in the control of basal and ascorbate stimulated mitochondrial glycolysis (2) In this study we have examined the effects of niacin and biotin on mitochondrial Fru 2 6 P_2

The results are shown in Fig 1 and Table I All three compounds were able to enhance the metabolite levels with a different time course ascorbate slowly raised Fru 2 6 P_2 to values which remained constant within 2 hours whereas niacin was responsible for a sustained increase of the metabolite levels with a maximum at 30 min and a subsequent progressive decrease biotin showed a similar behaviour with a maximum at 15 min

Fig 1 Levels of Fru 2 6 P_2 in mitochondria incubated in 5mM glucose alone or plus ascorbate (10 mg/ml) niacin (250 ng/ml) or biotin (20µg/ml) Means of 3 expts

Ascorbate is responsible for a permanent activation of protein kinase C whereas niacin and biotin induce a transient activation of this enzyme regarded as one of the important cellular signal transducers (5) We observed permanent enhancement of Fru 2 6 P_2 elicited by ascorbate and the transients induced by niacin and biotin closely resembling respective patterns of protein kinase C activation suggesting the possible involvement of this enzyme in the control of Fru-2 6 P_2

The mitochondrial response is at least in part due to Ca^{++} mobilization therefore the effect of the divalent cation on Fru 2 6 P_2 levels has been investigated using a low concentration of the ionophore B6360 (Table I) Ca^{++} appears to enhance Fru 2 6 P_2 concentration and, interestingly its action is additive to that exerted by niacin and biotin

Table I Effect of ionophore B6360 on mitochondrial Fru 2,6 P_2 levels

	Fru 2 6 P_2 (pmol/mg protein)	
Addition	—	+ 0 1µM B6360 1 mM Ca^{++}
none	6 0 ± 0 3	12 8 ± 0 3
niacin 250 ng/ml	10 9 ± 0 2	18 8 ± 0 6
biotin 20 µg/ml	11 6 ± 0 4	21 0 ± 0 4

Mitochondria were incubated for 15 min in the presence or absence of the above mentioned substances

Data reported are the means of experiments performed in triplicate

From the present study it emerges that Fru 2 6 P_2 metabolism is under the control of protein kinase C and of molecular events linked to Ca^{++} mobilization which likely exert their action by regulating the enzyme responsible for the synthesis of the bisphosphate

INTERNATIONAL CENTRE FOR GENETIC ENGINEERING AND BIOTECHNOLOGY (ICGEB)

MOLECULAR AND GENETIC APPROACHES TO PLANT STRESS

15–17 February 1990, New Delhi, India

Invited speakers and moderators include:
M. Bhattacharyya (St. Louis, USA), F.R. Bidinger (ICRISAT, India), C.-W. Chi (Shanghai, PR China), Y.-L. Fan (Beijing, PR China), A. Gatehouse (Durham, UK), T.K. Hodges (West Lafayette, USA), R. Hull (Norwich, UK), R. Johnson (Pullman, USA), K. Kloppstech (Hannover, FRG), J. Leach (Manhattan, USA), J. Manners (Brisbane, Australia), J. Mullet (College Station, USA), K.S. Nwanze (ICRISAT, India), H. Pakrasi (St. Louis, USA), J. Peacock (ICRISAT, India), R.S. Rana (New Delhi, India), M.A. Rezaian (Adelaide, Australia), E.A. Siddiq (Hyderabad, India).

Sessions will cover:
Plant viruses, fungal diseases, pest resistance, insecticidal proteins, plant transformation and regeneration, RFLP analysis, stress-regulated gene expression, genetic variation in pathogens and pasts, heritability of resistance to abiotic stress, herbicide degradation and resistance. Two poster sessions will allow participants to present their work.

Registration:
The Symposium will be held at the Ashok Hotel, New Delhi, with registration on Wednesday, 14th February.

Aims:
The Symposium will bring together molecular biologists and geneticists concerned with biotic and abiotic stress in plants. Lectures and discussions will focus on the use of molecular, cellular and genetic techniques to accelerate the breeding of plants with enhanced stress resistance. Since ICGEB has a mandate for research and advanced teaching in genetic engineering and biotechnology for the benefit of developing countries, applications are especially welcome from citizens of these countries. A limited number of travel scholarships are available for applicants from ICGEB member countries.

Application:
The deadline for applications is 14th December 1989. Applications may be made by post or by fax and should include a curriculum vitae, a brief description of research interests, and a fax or telex number for reply. The organizers will notify those who have been accepted as soon as possible after the deadline. The total number of participants will be limited to about 100. Applications should be addressed to **Mr. G. Chatterjee, Administrative Officer, ICGEB, NII Campus, Shaheed Jeet Singh Marg, New Delhi-110067, India (fax: 91-11-6862316).** Successful applicants will be expected to present a paper. (W6453)M

SYMPOSIUM ON HUMAN GENOME RESEARCH: STRATEGIES AND PRIORITIES

29–31 January 1990

UNESCO Headquarters, 7 Place de Fontenoy, 75007 Paris, France

This Symposium, organized by G. Bernardi (Paris), F. Gros (Paris), V. Sgaramella (Pavia), M. Singer (Washington), and N. Zinder (New York), is co-sponsored by the Committee on Genetic Experimentation (COGENE) of the International Council of Scientific Unions (ICSU), the European Economic Community (EEC), the Federation of European Biochemical Societies (FEBS), the International Union of Biochemistry (IUB), and the United Nations Educational, Scientific and Cultural Organization (UNESCO).

The aim of the Symposium is to review the present status of genome research and to discuss its future developments especially in Europe, as well as the participation of developing countries.

The program will comprise the following Sessions:

1. The genomes of bacteria, yeast, plants and invertebrates. Chairman: F Jacob (Paris); S D Ehrlich (Jouy en Josas), H. Feldmann (Munich), F. Kafatos (Harvard, Heraklion), J. Schell (Cologne).

2. The human genome: organization, genetic and physical mapping. Chairman: J. Watson (Cold Spring Harbor); G. Bernardi (Paris), A. Bird (Vienna), W.R A. Brown (Oxford), K. Gardiner (Denver), T. Ikemura (Mishima), D Schlessinger (St. Louis), M. Singer (Washington), R White* (Salt Lake City).

3. The human genome: developments in experimental approaches. Chairman: P. Berg (Stanford); W. Ansorge (Heidelberg), J. Celis (Aarhus), H Lehrach (London), A. Mirzabekov (Moscow), M. Olson* (St. Louis), V. Sgaramella (Pavia), M. van der Ploegh (Leiden).

4. The human genome: genetic diseases. Chairman: J Dausset (Paris); T Caskey* (Houston), D Cohen (Paris), K. Davies* (Oxford), B. Jordan (Marseille), J L. Mandel (Strasbourg), J. Weissenbach (Paris), H. Zachau (Munich).

5. Genome projects under way. Chairman: W. Gilbert (Harvard); A.A. Bayev (Moscow), C. Cantor (Berkeley), R Dulbecco (La Jolla), P Fasella (Bruxelles), K. Matsubara (Japan), L Philipson (Heidelberg), G. Tocchini-Valentini* (Rome), N Zinder (New York).

6. The participation of developing Countries and of international organizations. Chairman: R. Dulbecco (La Jolla); J Allende* (Santiago), A. Falaschi (Trieste), K. Tewari* (New Dehli), J. Tooze (Heidelberg) and others.

7. Genome Research: a critical assessment of strategies. Chairman: W. Arber (Basel); E. Barnard (London), R. Weinberg (MIT) and others.

8. Genome Research: ethical and legal problems. Chairman: J. Kendrew (Cambridge); B. Muller-Hill (Cologne), P. Starlinger (Cologne) and others.

Invited participants include M. Ashburner* (Cambridge), F. Ben Hamida (Tunis), A. Bernardi (Gif-sur-Yvette), U. Bertazzoni (Bruxelles), A Boué (Paris), A. Bussard (Nice), F Chapeville (Paris), O. Ciferri (Pavia), B F.C. Clark (Aarhus), J.M. Claverie (Paris), G Cohen (Paris), S Cohen (Stanford), C. Coutelle (Berlin), P. Day (New Brunswick), K. Dellagi (Tunis), J.P. Ebel (Strasbourg), M. Fellous (Paris), J Frézal (Paris), F. Galibert (Paris), G. Georgiev (Moscow), A. Goffeau (Louvain), S Grisolia (Valencia), M. Grunberg-Manago (Paris), A. Kahn (Paris), J.C. Kaplan (Paris), E. Katchalski-Katzir (Rehovoth), R. Keynes (Cambridge), G Macaya (Costa Rica), J. Marton-Lefèvre (Paris), W. Mommaerts (Heidelberg), O.O Ole-MoiYoi (Nairobi), S. Panyim (Bangkok), C Rolz (Guatemala), J. Rosa (Paris), A. Rynditch (Kiev), G. Salvatore (Naples), M Siniscalco (Alghero), A.M. Skalka (Philadelphia), K. Skryabin (Moscow), R.G. Tsanev (Sofia), P Venetianer* (Szeged), T. Younes (Paris) (Asterisks indicate participations not yet confirmed).

Applications for participating in the Symposium (including a C.V. and a list of recent publications) should be sent to **G. Bernardi, Laboratoire de Génétique Moléculaire, Institut Jacques Monod, 2 Place Jussieu, 75005 Paris, France.** The registration fee will be 300 US Dollars. Participants below the age of 31 will be entitled to a reduced fee and may apply for FEBS Fellowships covering the fee, travel and living expenses (This is an amended version of the announcement published on October 21, 1989). THE CARE TO MEET, TO KNOW, TO UNDERSTAND

Ares-Serono Symposia is an independent foundation, created in 1971, to promote scientific research in all disciplines which contribute towards improving human health. This aim is pursued by means of congresses, courses, seminars and specialized studies.

Some of the international meetings scheduled for 1990 are:

Cytokines: Basic Principles and Clinical Applications
Florence / March 26-28
Scientific Organization: A.K. Abbas (USA) and S. Romagnani (I)

Hormonal Communicating Events in the Testis
Rome / April 9-10
Scientific Organization: M.L. Dufau (USA) and A. Isidori (I)

Reproduction, Growth and Development. V Pan-American Congress of Andrology
Acapulco / April 23-25
Scientific Organization: A. Negro-Vilar (USA) and G. Perez-Palacios (MEX)

Computers in Endocrinology
Milan / May 7-10
Scientific Organization: V. Guardabasso (I), G. Forti (I) and D. Rodbard (USA)

Major Advances in Human Female Reproduction
Rome / May 10-12
Scientific Organization: E.Y. Adashi (USA) and S. Mancuso (I)

The New Biology of Steroid Hormones
Budapest / September 3-4
Scientific Organization: F. Naftolin (USA)

Endocrinology Under 35
Siena / October 8-10
Scientific Organization: M. Maggi (I)

Plasminogen Activators: from Cloning to Therapy
Florence / October 29-31
Scientific Organization: T. Astrup (DK) and G.G. Neri Serneri (I)

IV Conference on Differentiation Therapy
Yamanashi-ken, Japan / November 4-9
Scientific Organization: G.B. Rossi (I), F. Takaku (J) and S. Waxman (USA)

Catch your glycoprotein!

Glycan Detection Kit

from Boehringer Mannheim

The new DIGOXIGENIN based carbohydrate immunodetection system guarantees you:

- **High specificity:**
  only glycoconjugates are detected
- **High sensitivity:**
  as few as 10 ng of glycoprotein is easily detected
- **Fast performance:**
  less than one working day is needed

For further details on this kit please ask your local representative or
